24-Bit 105 dB Audio Codec with Volume Control

Features

- 105 dB Dynamic Range A/D Converters
- 105 dB Dynamic Range D/A Converters
- 110 dB DAC Signal-to-Noise Ratio (EIAJ)
- Analog Volume Control (CS4224 only)
- Differential Inputs
- Differential Outputs
- On-chip Anti-aliasing and Output Smoothing Filters
- De-emphasis for 32, 44.1 and 48 kHz
- Supports Master and Slave Modes
- Single +5 V power supply
- On-Chip Crystal Oscillator
- 3 - 5 V Digital Interface

Description

The CS4223/4 is a highly integrated, high performance, 24-bit, audio codec providing stereo analog-to-digital and stereo digital-to-analog converters using delta-sigma conversion techniques. The device operates from a single +5 V power supply, and features low power consumption. Selectable de-emphasis filter for 32, 44.1, and 48 kHz sample rates is also included.

The CS4223/4 also includes an analog volume control capable of 113.5 dB attenuation in 0.5 dB steps. The analog volume control architecture preserves dynamic range during attenuation. Volume control changes are implemented using a "soft" ramping or zero crossing technique.

Applications include digital effects processors, DAT, and multitrack recorders.

The CS4223/4 is packaged in a 28-pin plastic SSOP.

ORDERING INFORMATION

CS4223-KS -10 to +70 °C 28-pin SSOP
CS4224-KS -10 to +70 °C 28-pin SSOP

Notes:

1. Referenced to typical full-scale differential input voltage (2 Vrms).
2. Filter characteristics scale with output sample rate. For output sample rates, Fs, other than 48 kHz, the 0.01 dB passband edge is 0.4535x Fs and the stopband edge is 0.625x Fs.
3. The analog modulator samples the input at 6.144 MHz for an Fs equal to 48 kHz. There is no rejection of input signals which are multiples of the sampling frequency (n x 6.144 MHz ±21.8 kHz where n = 0,1,2,3...).
4. Group delay for Fs = 48 kHz, \(t_{gd} = 15/48 \, \text{kHz} = 312 \, \mu\text{s}.

* Parameter definitions are given at the end of this data sheet.
Specifications are subject to change without notice.

4. FUNCTIONAL DESCRIPTION

4.1. Overview

The CS4223/4 has 2 channels of 24-bit analog-to-digital conversion and 2 channels of 24-bit digital-to-analog conversion. All ADCs and DACs are delta-sigma converters. The DAC outputs on the CS4224 have adjustable output attenuation implemented in 0.5 dB step resolution. The device also includes digital de-emphasis for 32, 44.1, and 48 kHz.

Digital audio data for the DACs and from the ADCs is communicated over separate serial ports. This allows concurrent writing to and reading from the device. The CS4223 is a stand-alone device controlled via pins. Control for the functions available on the CS4224 are communicated over a serial microcontroller interface. Figures 4 and 5 show the recommended connection diagram for the CS4223 and CS4224.

The CS4224 supports additional functions through the control port interface as outlined in Table 1.

Table 1. CS4224 vs. CS4223

4.2. Analog Inputs

4.2.1 Line Level Inputs

AINR-, AINR+, AINL-, and AINL+ are the differential line level input pins (See Figures 4 and 5). Figure 6 shows an AC coupled optional input buffer which combines level shifting with single-ended to differential conversion. Analog inputs may be AC coupled or DC coupled into the CS4223/4 with a 2.3 V common mode input voltage. Any DC offset at the input to the CS4223/4 will be removed by the internal high-pass filters (see Figure 8 for the differential input signal description). The CS4223/4 may also be driven with a single-ended input as illustrated in Figure 7. The ADC outputs in the CS4224 may be muted (set to zero) by writing the ADMR and ADML bits. ADMR, ADML, and PDN are all located in the ADC control byte (#1).

4.2.2 Input Level Monitoring (CS4224 only)

The CS4224 includes independent Peak Input Level Monitoring for each channel. The analog-to-digital converter continually monitors the peak digital signal for both channels, prior to the digital limiter, and records these values in the LVL2-0 (left channel) and LVR2-0 (right channel) bits in the Converter Status Report Byte (#6). These bits indicate whether the input level is clipping, -1 to -6 dB from full scale in 1 dB resolution, or below -6 dB from full scale. The LVL/LVR bits are "sticky" bits and are reset to zero when read.

4.2.3 High Pass Filter

The operational amplifiers in the input circuitry driving the CS4223/4 may generate a small DC offset into the A/D converter. The CS4223/4 includes a high pass filter after the decimator to remove any DC offset which could result in recording a DC level, possibly yielding "clicks" when switching between devices in a multichannel system. The characteristics of this first-order high pass filter are outlined below for Fs equal to 48 kHz. The filter re-
Figure 6. Optional Line Input Buffer

Figure 7. Single-ended Input Application
response scales linearly with sample rate. The high pass filter in the CS4224 may be defeated independently for the left and right channels by writing HPDR and HPDL in the ADC control byte (#1).

Table 2. High Pass Filter Characteristics

4.3. Analog Outputs

4.3.1 Line Level Outputs

The CS4223/4 contains an on-chip buffer amplifier producing differential outputs capable of driving 10 kΩ loads. Each output (AOUTL+, AOUTL-, AOUTR+, AOUTR-) will produce a nominal 2.83 Vpp (1 Vrms) output with a 2.3 volt common mode for a full scale digital input. This is equivalent to a 5.66 Vpp (2 Vrms) differential signal as shown in Figure 8. The recommended off-chip analog filter is either a 2nd order Butterworth or a 3rd order Butterworth, if greater out-of-band noise filtering is desired. The CS4223/4 DAC interpolation filter has been pre-compensated for an external 2nd order Butterworth filter with a 3 dB corner at Fs, or a 3rd order Butterworth filter with a 3 dB corner at 0.75 Fs to provide a flat frequency response and linear phase over the passband (see Figure 9 for Fs = 48 kHz). If the recommended filter is not used, small frequency response magnitude and phase errors will occur. In addition to providing out-of-band noise attenuation, the output filters shown in Figure 9 provide differential to single-ended conversion.

4.3.2 Analog/Digital Volume Control (CS4224 only)

The DAC outputs are each routed through an attenuator which is adjustable in 0.5 dB steps. Output attenuation is available through the Output Attenuator Data Bytes (#3 & #4). Level changes are implemented with an analog volume control until the residual output noise is equal to the noise floor in the mute state at which point volume changes are performed digitally. This technique is superior to purely digital volume control techniques as the noise is attenuated by the same amount as the signal, thus preserving dynamic range (see Figure 10).

The CS4224 implements a "soft" volume control whereby level changes are achieved by ramping from the current level to the new level in 0.5 dB steps. The default rate of volume change is 8 LRCK cycles for each 0.5 dB step (equivalent to 647 µs at Fs = 48 kHz). The rate of volume change is adjustable to 4, 16, or 32 LRCK cycles with the RMP1/0 bits in the DAC control byte (#2).

"Soft" volume control may be disabled through the SOFT bit in the DAC bit Control Byte (#2). When "soft" volume control is defeated, level changes step from the current level to the new level in a single step. The volume change takes effect on a zero crossing to minimize audible artifacts. If there is no zero crossing, then the requested level change will occur after a time-out period between 512 and 1024 sample periods (10.7 ms to 21.3 ms at 48 kHz sample rate). There is a separate zero crossing detector for each channel. ACCR and ACCL bits in the Converter Status Report Byte (#6) give feedback when a volume control change has taken effect for the right and left channel. This bit goes high when a new setting is loaded and returns low when it has taken effect.

Figure 8. Full Scale Input/Output Voltage
Figure 9. 2- and 3-Pole Butterworth Filters

Figure 10. Hybrid Analog/Digital Attenuation
4.3.3 Soft Mute/Mute on Zero Input Data (CS4224 only)

Muting is achieved by software control. Under software control, each output can be independently muted via mute control bits, MUTR and MUTL, in the DAC Control Byte (#2). Soft mute output level will ramp down in 0.5 dB steps to a muted state or zero crossing mute will be implemented depending on the state of the SOFT bit in the DAC Control Byte (#2). When "soft" mute is defeated, muting occurs on zero crossings or after a time-out period, similar to the volume control changes.

Muting on consecutive zero input data is also provided where all DAC outputs will mute if they receive between 512 and 1024 consecutive zeros (or -1 code). Detection and muting is done independently for left and right channels. A single non-zero value will immediately unmute the DAC output. This feature is disabled on power-up, and it may be enabled with the MUTC bit in the DAC Control Byte (#2).

4.4. Master Clock Generation

The Master Clock, XTI, is used to operate the digital filters and the delta-sigma modulator. XTI must be either 256x, 384x, or 512x the desired Input Sample Rate, Fs. Fs is the frequency at which digital audio samples for each channel are input to the DAC or output from the ADC and is equal to the LRCK frequency. The XTI to LRCK frequency ratio is detected automatically during the initialization sequence by counting the number of XTI transitions during a single LRCK period. Internal dividers are then set to generate the proper clocks for the digital filters, delta-sigma modulators and switched-capacitor filter. Table 3 illustrates the standard audio sample rates and the required XTI frequencies. If XTI stops for 10 µs, the CS4223/4 will enter a power down state until the clock returns. The control port registers will maintain their current settings. It is required to have SCLK and LRCK derived from the master clock.

\[
\begin{array}{|c|c|c|c|}
\hline
\text{Fs (kHz)} & \text{XTI (MHz)} \\
\hline
\text{256x} & 8.1920 & 12.2880 & 16.3840 \\
\text{384x} & 11.2896 & 16.9344 & 22.5792 \\
\text{512x} & 12.2880 & 18.4320 & 24.5760 \\
\hline
\end{array}
\]

Table 3. Common Clock Frequencies

4.5. Master vs. Slave Mode

The CS4223/4 may be operated in both Master mode (LRCK and SCLK are outputs) and Slave mode. When a 47 kΩ pulldown resistor is present on SDOUT at startup or after reset, the part will operate in master mode (see Figure 5). Table 4 outlines the various clocking modes for Master and Slave modes for the CS4223 and CS4224.

Table 4. Master Mode vs. Slave Mode Clocking.

Notes: 15. Register #7 must be programmed within 1 (ms) after RST de-asserted.
4.6. Serial Audio Data Interface

4.6.1 Serial Audio Interface Signals

The serial interface clock, SCLK, is used for transmitting and receiving audio data. Data is valid on the rising edge of SCLK for both input and output data in the CS4223. In the CS4224, the active edge of SCLK is chosen by setting the DSCK bit in the DSP Port Mode Byte (#5). Data is valid on the rising edge for both input and output upon power up default. SCLK is an input from an external source and at least 24 SCLK’s per half period of LRCK are required for proper operation.

The Left/Right clock (LRCK) is used to indicate left and right data and the start of a new sample period. The frequency of LRCK must be equal to the system sample rate, Fs.

SDIN is the data input pin which drives a pair of DACs. SDOUT is the output data pin from the ADCs.

4.6.2 Serial Audio Interface Formats

The serial audio port supports 4 input and 4 output formats, shown in Figure 11. With the CS4223, the interface formats are chosen via the DIF0/DIF1 pins. With the CS4224, these formats are chosen through the DSP Port Mode Byte (#5) with the DDO and DD12/1/0 bits. The data output format is 24 bits and may be left justified or I2S compatible depending on the state of the DDO bit. The input data format is set with the DDI bits to be left or right justified or I2S compatible. When using right-justify mode for SDOUT, SCLK must be 64 Fs in slave mode. In addition, the polarity of the SCLK edge used to clock in/out data from the CS4224 may be set via the DSCK bit in the DSP Port Mode Byte (#5). The default input and output format for the CS4224 is I2S compatible.

4.7. Control Port Interface (CS4224 only)

The control port is used to load all the internal settings. The operation of the control port may be completely asynchronous with the audio sample rate. However, to avoid potential interference problems, the control port pins should remain static if no operation is required.

The control port has 2 modes: SPI® and I2C®, with the CS4224 operating as a slave device. The control port interface format is selected by the SPI/I2C pin.

![Figure 11. Audio DSP Data Input Formats.](image-url)
4.7.1 SPI Mode

In SPI mode, $\overline{\text{CS}}$ is the CS4224 chip select signal, CCLK is the control port bit clock, CDIN is the input data line from the microcontroller and the chip address is 0010000. All signals are inputs and data is clocked in on the rising edge of CCLK.

Figure 12 shows the operation of the control port in SPI mode. To write to a register, bring $\overline{\text{CS}}$ low. The first 7 bits on CDIN form the chip address, and must be 0010000. The eighth bit is a read/write indicator ($R/W$), which must be low to write. Register reading from the CS4224 is not supported in the SPI mode. The next 8 bits form the Memory Address Pointer (MAP), which is set to the address of the register that is to be updated. The next 8 bits are the data which will be placed into a register designated by the MAP.

The CS4224 has a MAP auto increment capability, enabled by the INCR bit in the MAP register. If INCR is a zero, then the MAP will stay constant for successive writes. If INCR is set to a 1, then MAP will auto increment after each byte is written, allowing block writes of successive registers. Register reading from the CS4224 is not supported in the SPI mode.

4.7.2 $I^2$C Mode

In $I^2$C mode, SDA is a bidirectional data line. Data is clocked into and out of the part by the clock, SCL, with the clock to data relationship as shown in Figure 13. There is no $\overline{\text{CS}}$ pin. Pin AD0 forms the partial chip address and should be tied to VD or DGND as desired. The upper 6 bits of the 7 bit address field must be 001000. In order to communicate with the CS4224, the LSB of the chip address field (first byte sent to the CS4224) should match the setting of the AD0 pin. The eighth bit of the address byte is the $R/W$ bit (high for a read, low for a write). If the operation is a write, the next byte is the Memory Address Pointer which selects the register to be read or written. If the operation is a read, the contents of the register pointed to by the Memory Address Pointer will be output. Setting the auto increment bit in MAP, allows successive reads or writes of consecutive registers. Each byte is separated by an acknowledge bit.
4.7.3 Control Port Bit Definitions

All registers can be written and read in I²C mode, except the Converter Status Report Byte (#6) and the CLKE and CALP bits in the ADC control byte (#1) which are read only. SPI mode only allows for register writing (see the following bit definition tables for bit assignment information).

4.8. De-Emphasis

The CS4223/4 is capable of digital de-emphasis for 32, 44.1, or 48 kHz sample rates. Implementation of digital de-emphasis requires reconfiguration of the digital filter to maintain the filter response at multiple sample rates (see Figure 14).

De-emphasis control is achieved with the DEM1/0 pins on the CS4223 or through the DEM1-0 bits in the DSP Port Mode Byte (#5) on the CS4224. The CS4223 de-emphasis control is defined in Table 5.

<table>
<thead>

<td>OFF</td>
</tr>
</tbody>
</table>

Table 5. CS4223 De-Emphasis filter control

4.9. Power-up / Reset / Power Down / Calibration

Upon power up, the user should hold \( \text{RST} = 0 \) for approximately 10 ms. In this state, the control port is reset to its default settings and the part remains in the power down mode. At the end of \( \text{RST} \), the device performs an offset calibration which lasts approximately 50 ms after which the device enters normal operation. In the CS4224, a calibration may also be initiated via the CAL bit in the ADC Control Byte (#1). The CALP bit in the ADC Control Byte is a read only bit indicating the status of the calibration.

Reset/Power Down is achieved by lowering the \( \text{RST} \) pin causing the part to enter power down. Once \( \text{RST} \) goes high, the control port is functional and the desired settings should be loaded.

The CS4223/4 will also enter power down mode if the master clock source stops for approximately 10 µs or if the LRCK is not synchronous to the master clock. The control port will retain its current settings.

If PDN is set to 1, the chip will power down.

The CS4223/4 will mute the analog outputs and enter the power down mode if the supply drops below approximately 4 volts.

4.10. Power Supply, Layout and Grounding

The CS4223/4 should be located on the analog ground plane along with associated analog circuitry and should be positioned near the split between ground planes (see Figure 15). Preferably, the device should also have its own power plane. The +5 V supply should be connected to the CS4223/4 via a ferrite bead, positioned closer than 1” to the device. A single connection between the CS4223/4 ground and the board ground should be positioned as shown in Figure 15. See the CDB4223/4 evaluation board data sheet for recommended layout of the decoupling components.
Note that the CS4223/4 is oriented with its digital pins towards the digital end of the board.

Figure 15. Suggested Layout Guideline (See CDB4223/4 Data Sheet)
4.11. ADC and DAC Filter Response Plots

3 - -4 dB level  
4 - -3 dB level  
5 - -2 dB level  
6 - -1 dB level  
7 - Clipping

LVL2-0 and LVR2-0 bits are ‘sticky’. They constantly monitor the ADC output for the peak levels and hold the maximum output. They are reset to 0 when read.

This register is read only.

MCK1-0 Master Clock Control
0 - XTI = 256 for Master Mode
1 - XTI = 384 for Master Mode
2 - XTI = 512 for Master Mode

The setting of these bits are not valid in Slave Mode.

This register defaults to 0.
6. PIN DESCRIPTIONS — CS4223

Power Supply

Positive Analog Power — VA

*Pin 21*

*Function:* Positive analog supply. Nominally +5 volts.

Positive Digital Power — VD

*Pin 6*

*Function:* Positive supply for the digital section. Nominally +5 volts.

Positive Digital Logic Power — VL

*Pin 13*

*Function:* Positive supply for the digital interface section. Nominally 3-5 volts.

Analog Ground — AGND

*Pin 22*

*Function:* Analog ground reference.

Digital Ground — DGND

*Pin 7*

*Function:* Digital ground for the digital section.
**Analog Inputs**

**Differential Right Channel Analog Input — AINR-, AINR+**  
*Pins 16 and 17*  
*Function:*  
Analog input connections of the right channel differential inputs. Typically 2 Vrms differential (1 Vrms for each input pin) for a full-scale analog input signal.

**Differential Left Channel Analog Input — AINL-, AINL+**  
*Pins 19 and 20*  
*Function:*  
Analog input connections of the left channel differential inputs. Typically 2 Vrms differential (1 Vrms for each input pin) for a full-scale analog input signal.

**Analog Outputs**

**Differential Right Channel Analog Outputs — AOUTR-, AOUTR+**  
*Pins 23 and 24*  
*Function:*  
Analog output connections for the Right channel differential outputs. Nominally 2 Vrms (differential) for full-scale digital input signal.

**Differential Left Channel Analog Outputs — AOUTL-, AOUTL+**  
*Pins 25 and 26*  
*Function:*  
Analog output connections for the Left channel differential outputs. Nominally 2 Vrms (differential) for full-scale digital input signal.

**Digital Inputs**

**Crystal Connections — XTI, XTO**  
*Pins 3, 2*  
*Function:*  
Input and output connections for the crystal used to clock the CS4223. Alternatively a clock may be input into XTI. This is the clock source for the delta-sigma modulator sampling and digital filters. The frequency of this clock must be either 256x, 384x, or 512x Fs in Slave Mode and 256x in Master Mode.

**Left/Right Clock — LRCK**  
*Pin 4*  
*Function:*  
LRCK determines which channel, left or right, is to be input/output on SDIN/SDOUT. Although the outputs for each ADC channel are transmitted at different times, Left/Right pairs represent simultaneously sampled analog inputs. LRCK is an input clock whose frequency must be equal to Fs.
Serial Data Clock — SCLK

Pin 5
Function:
Clocks the individual bits of the serial data out from SDOUT and in from SDIN.

Serial Data Input — SDIN

Pin 9
Function:
Two’s complement MSB-first serial data of either 20 or 24 bits is input on this pin. The data is clocked into the CS4223 via the SCLK clock and the channel is determined by the LRCK clock. The interface format is selected by the DIF0 and DIF1 pins.

De-Emphasis Select — DEM0, DEM1

Pins 12 and 18
Function:
Controls the activation of the standard 50/15 µs de-emphasis filter. 32, 44.1, or 48 kHz sample rate selection defined in Table 5.

Digital Input Format — DIF0, DIF1

Pins 11 and 10
Function:
These pins select one of four formats for the input/output serial data stream. These pins set the format of the SCLK and LRCK clocks with respect to SDATA. The formats are shown in Figure 11.

Digital Outputs

Serial Data Output — SDOUT

Pin 8
Function:
Two’s complement MSB-first serial data of 20-24 bits is output on this pin. The data is clocked out via the SCLK clock and the channel is determined by LRCK.

Miscellaneous Pins

Reset — RST

Pin 27
Function:
When low, the CS4223 enters a low power mode and all internal states are reset, including the control port. When high, the control port becomes operational and normal operation will occur.

No Connect — NC

Pins 1, 14, 15 and 28
Function:
These pins are not connected internally and should be tied to DGND to minimize noise coupling.

**Power Supply**

**Positive Analog Power — VA**

*Pin 21*

*Function:*

Positive analog supply. Nominally +5 volts.

**Positive Digital Power — VD**

*Pin 6*

*Function:*

Positive supply for the digital section. Nominally +5 volts.

**Positive Digital Logic Power — VL**

*Pin 13*

*Function:*

Positive supply for the digital interface section. Nominally 3-5 volts.

**Analog Ground — AGND**

*Pin 22*

*Function:*

Analog ground reference.

**Digital Ground — DGND**

*Pin 7*

*Function:*

Digital ground for the digital section.
Analog Inputs

Differential Right Channel Analog Input — AINR-, AINR+

Pins 16 and 17
Function:
Analog input connections of the right channel differential inputs. Typically 2 Vrms differential (1 Vrms for each input pin) for a full-scale analog input signal.

Differential Left Channel Analog Input — AINL-, AINL+

Pins 19 and 20
Function:
Analog input connections of the left channel differential inputs. Typically 2 Vrms differential (1 Vrms for each input pin) for a full-scale analog input signal.

Analog Outputs

Differential Right Channel Analog Outputs — AOUTR-, AOUTR+

Pins 23 and 24
Function:
Analog output connections for the Right channel differential outputs. Nominally 2 Vrms (differential) for full-scale digital input signal.

Differential Left Channel Analog Outputs — AOUTL-, AOUTL+

Pins 25 and 26
Function:
Analog output connections for the Left channel differential outputs. Nominally 2 Vrms (differential) for full-scale digital input signal.

Digital Inputs

Crystal Connections — XTI, XTO

Pins 3, 2
Function:
Input and output connections for the crystal used to clock the CS4224. Alternatively a clock may be input into XTI. This is the clock source for the delta-sigma modulator sampling and digital filters. The frequency of this clock must be either 256x, 384x, or 512x Fs. The default XTI setting in Master Mode is 256x, but this may be changed to 384x or 512x through the Control Port.

Left/Right Clock — LRCK

Pin 4
Function:
LRCK determines which channel, left or right, is to be input/output on SDIN/SDOUT. Although the outputs for each ADC channel are transmitted at different times, Left/Right pairs represent simultaneously sampled analog inputs. LRCK is an input clock whose frequency must be equal to Fs.
Serial Data Clock — SCLK

*Pin 5*

*Function:*
Clocks the individual bits of the serial data out from SDOUT and in from SDIN.

Serial Data Input — SDIN

*Pin 9*

*Function:*
Two’s complement MSB-first serial data of either 20 or 24 bits is input on this pin. The data is clocked into the CS4224 via the SCLK clock and the channel is determined by the LRCK clock. The default interface format on power-up is an I²S compatible 24-bit interface. This may be changed by writing the control port (DSP Port Mode Byte #5).

Control Port Format — I²C / SPI

*Pin 18*

*Function:*
When this pin is high, I²C mode is selected, when low, SPI is selected.

Digital Outputs

Serial Data Output — SDOUT

*Pin 8*

*Function:*
Two’s complement MSB-first serial data of 24 bits is output on this pin. The data is clocked out via the SCLK clock and the channel is determined by LRCK.

Control Port Signals

Serial Control Interface Clock — SCL/CCLK

*Pin 10*

*Function:*
SCL/CCLK is the serial control interface clock and is used to clock control bits into and out of the CS4224.

Address Bit/Control Port Chip Select — AD0/CS

*Pin 12*

*Function:*
In I²C mode, AD0 is a chip address bit. In SPI mode, CS is used to enable the control port interface on the CS4224. The CS4224 control port interface is defined by the SPI/I2C pin.

Serial Control Data In — SDA/CDIN

*Pin 11*

*Function:*
SDA/CDIN is the input data line for the control port interface.
Miscellaneous Pins

Reset — RST

Pin 27

Function:
When low, the CS4224 enters a low power mode and all internal states are reset, including the control port. When high, the control port becomes operational and normal operation will occur.

No Connect — NC

Pins 1, 14, 15 and 28

Function:
These pins are not connected internally and should be tied to DGND to minimize noise coupling.
8. PARAMETER DEFINITIONS

Dynamic Range
The ratio of the full scale rms value of the signal to the rms sum of all other spectral components over the specified bandwidth. Dynamic range is a signal-to-noise measurement over the specified bandwidth made with a -60 dBFS signal. 60 dB is then added to the resulting measurement to refer the measurement to full scale. This technique ensures that the distortion components are below the noise level and do not affect the measurement. This measurement technique has been accepted by the Audio Engineering Society, AES17-1991, and the Electronic Industries Association of Japan, EIAJ CP-307.

Total Harmonic Distortion + Noise
The ratio of the rms value of the signal to the rms sum of all other spectral components over the specified bandwidth (typically 20 Hz to 20 kHz), including distortion components. Expressed in decibels. ADCs are measured at -1 dBFS as suggested in AES17-1991 Annex A and DACs are measured at 0 dBFS.

Idle Channel Noise / Signal-to-Noise-Ratio
The ratio of the rms analog output level with 1 kHz full scale digital input to the rms analog output level with all zeros into the digital input. Measured A-weighted over a 10 Hz to 20 kHz bandwidth. Units in decibels. This specification has been standardized by the Audio Engineering Society, AES17-1991, and referred to as Idle Channel Noise. This specification has also been standardized by the Electronic Industries Association of Japan, EIAJ CP-307, and referred to as Signal-to-Noise-Ratio.

Total Harmonic Distortion (THD)
THD is the ratio of the test signal amplitude to the rms sum of all the in-band harmonics of the test signal. Units in decibels.

Interchannel Isolation
A measure of crosstalk between channels. Measured for each channel at the converter’s output with no signal to the input under test and a full-scale signal applied to the other channel. Units in decibels.

Frequency Response
A measure of the amplitude response variation from 20 Hz to 20 kHz relative to the amplitude response at 1 kHz. Units in decibels.

Interchannel Gain Mismatch
For the ADCs, the difference in input voltage that generates the full scale code for each channel. For the DACs, the difference in output voltages for each channel with a full scale digital input. Units are in decibels.

Gain Error
The deviation from the nominal full scale output for a full scale input.

Gain Drift
The change in gain value with temperature. Units in ppm/°C.

Offset Error
For the ADCs, the deviation in LSB’s of the output from mid-scale with the selected inputs tied to a common potential. For the DAC’s, the differential output voltage with mid-scale input code. Units are in volts.

Notes: 16. “D” and “E1” are reference datums and do not include mold flash or protrusions, but do include mold mismatch and are measured at the parting line, mold flash or protrusions shall not exceed 0.20 mm per side.

17. Dimension “b” does not include dambar protrusion/intrusion. Allowable dambar protrusion shall be 0.13 mm total in excess of “b” dimension at maximum material condition. Dambar intrusion shall not reduce dimension “b” by more than 0.07 mm at least material condition.

18. These dimensions apply to the flat section of the lead between 0.10 and 0.25 mm from lead tips.
