Select clean, coherent sinusoids at microwave frequencies. Wide-band synthesizer offers extended range with counter-like accuracy. Seven digital switches resolve frequencies in steps of 10 kHz; spectrally-pure signals from 1 to 12.4 GHz are instantly at hand. For a full readout on the specs and applications—see page 102.
TRW 50-volt Metallized Polycarbonate Capacitors are made to squeeze into tight places. Imagine 10 microfarads measuring .547” x 1 1/4” long... the smallest wound capacitor on the market!

Short on size and long on reliability, the X463UW series meets all requirements of MIL-C-27287.

- **VOLTAGE**—50V, 100V, 200V, 400V
- **CAPACITANCE**—.001 through 10 mfd
- **TOLERANCE**—available to ±1%

For data, write TRW Capacitor Div., Ogallala, Neb. Phone (308) 284-3611. TWX 910-620-0321.
The HP Vector Voltmeter tells all.

"All" means phase, the key to every RF measurement. Especially the tough ones like open-loop gain of feedback amplifiers, electrical lengths, resonance characteristics, or filter pass and rejection bands. And this 2-channel millivoltmeter-phasemeter makes them directly, accurately and conveniently.

The Vector Voltmeter covers the frequency range from 1 to 1000 MHz and automatically locks onto the signal anywhere within an octave—no fine tuning required. It’s extremely sensitive—full scale 100 µV. With its 90 dB dynamic range, you can easily measure high gain and high loss networks. It has a 360-degree phase range with 0.1° resolution. The 8405A also serves as a "frequency translator." How? By transforming the RF inputs to 20 kHz outputs whose wave shapes, amplitudes and phase relationship remain identical to the original RF signals. You can use these outputs for further analysis with low frequency scopes.

You needn’t waste time making a tough RF measurement any longer. The HP 8405A does it faster and more completely than ever before. Application Note 91 tells you how. Just call your HP field engineer for details, or write Hewlett-Packard, Palo Alto, California 94304; Europe: 54 Route des Acacias, Geneva.

VARIABLE RISE PULSE GENERATOR WITH PRECISION DC BASELINE OFFSET

The Datapulse Model 111 extends general purpose pulse generator technology a full octave in rise time capability, with full control over every major pulse parameter. No other pulse generator is so ideally suited for high speed integrated circuit testing and digital logic circuit design.

SPECIFICATIONS — 2 ns to 500 ns linear rise, 4 Hz to 40 MHz repetition rates, ±5V output into 50 ohms, precision baseline offset to ±5V with ±50mV accuracy, single or double pulse operation, 50 MHz simulated rep rates on double pulse, and 8 ns to 500 µs pulse widths. • PRICE: $1480.00

TYPICAL APPLICATIONS —

20ns/cm, 1V/cm

The 111's fully controllable fast pulses permit construction of a nearly limitless number of test waveforms for the design and test of high speed components, integrated circuits, analog devices, and other elements.

0.3V/cm, 5 ns/cm

Independently variable, linear rise and fall times permit marginal testing and exact simulation of pulse circuit rise and fall times.

10 ns/cm, 0.5V/cm

Narrow pulse output to 8 nanoseconds provides impulse type signals for high speed circuit development, high frequency complex impedance analysis, and other transient tests.

2V/cm, 20 ns/cm

Precision variable baseline level provides dc biased outputs for off-ground logic simulation; also for worst case tolerancing of logic circuitry and noise susceptibility analysis.

2V/cm, 0.1 µs/cm

Double pulse operation provides two identical pulses in each cycle. Ideal for flip-flop resolution checks, navigational signal simulation.

Today, your I/C logic system is only half as fast as it could be...
MECL III picosecond logic is here!

At last, fourth-generation computer designs and highly-sophisticated instrumentation designs have become a reality, thanks to the ultra-high speeds that are now possible through the current mode logic of MECL III!

Three different circuits in this new line of emitter-coupled devices are currently available for evaluation. MC1060S and MC1062S, dual 4 and quad 2-input gates, offer propagation delay times that are typically 900 picoseconds when operated into a 510 ohm load. Reduce the load an order of magnitude and the delay time is only 1.1 nanoseconds; still twice as fast as any comparable form of logic.

In addition, MC1070S, single phase, type "D" Flip-Flop, provides a toggle/shift frequency that is typically 350 MHz. And, it can be "tweaked" to higher frequencies by application of an external bias.

The standard MECL III package is a stud-mounted, 15-pin ceramic flat pack. The stud, connected to $V_m$, is designed to improve heat dissipation.

For further information about MECL III or for individual evaluation units, contact us at the address below. Don’t wait another day to begin designing the picosecond logic of tomorrow’s fourth generation computers.

MECL III picosecond logic available in prototype kit

Six MECL III circuits plus a design information brochure are packaged in a useful, compact kit. Devices include two each of the three circuits described here. The advance information brochure contains device specifications plus design rules and applications information. The entire package is available through your Motorola Semiconductor Representative for $154.00 (any quantity).
Flexibility.
And we'll give you a good reason to buy our flexible circuits over anyone else's:
We make them with the same kind of precision our regular printed circuits are known for.
We can produce them in quantity to the most stringent specifications—single or multilayer.

We're probably the flexible circuit source you've been looking for.
For your copy of "A Designer's Guide to Flexible Circuits," write to Printed Circuits, Lockheed Electronics Company, Data Products Division, 6201 E. Randolph St., Los Angeles, California 90022.

We've added a new wrinkle to our printed circuits.

LOCKHEED ELECTRONICS COMPANY
A Division of Lockheed Aircraft Corporation
MAKES THE HP 675A SWEEPER
A NETWORK ANALYZER...
Simultaneously display phase and amplitude!

Now you have both phase and amplitude information on a swept basis to 32 MHz. You save hours of time, see changes in phase and amplitude responses immediately as you make adjustments. This combination of instruments is oriented toward production and lab testing.

The 675A Sweeping Signal Generator has a 10 kHz to 32 MHz range with settings anywhere in this range for single or continuous sweep. The 676A Phase/Amplitude Tracking Detector adds a full 360° phase measurement capability and an 80 dB dynamic amplitude range. Combination is programmable for automatic or computerized testing.

Channel A and B outputs of the 676A provide simultaneous amplitude measurements of two devices for comparison. Amplitude A-B and PHASE A-B make difference measurements easy. Outputs can be easily calibrated in linear dB and linear phase on a low frequency oscilloscope or X-Y recorder. New active probe (100 kΩ, 3.5 pF) augments 50 Ω input for high impedance measurements.

Check your design and production areas for the savings you can make with the new network analyzer—the combination that makes point-to-point plotting passe. Call your local HP field engineer for complete information. Or, write Hewlett-Packard, Palo Alto, California 94304. Europe: 54 Route des Acacias, Geneva. Price: 675A, $2250; 676A, $1275.

ANBIENT TEMPERATURE \( T_a = 25^\circ C \)

The most reliable high-speed tunnel diodes you can design around—combining speed with reliability and hermeticity—are the RCA “TD-II” family of units. Type numbers from RCA 40561 to 40574 (axial-lead version of RCA types 1N3847 to 1N3860) make up a full line covering the spectrum of your needs. The chart above gives \( I_c \) in ps (typ.) and \( I_c \) in mA/pF typ. Go down the line and find your exact needs!

These units are designed for extremely critical switching and signal-processing applications requiring tight control \((\pm 5\%)\) of peak-point currents and rise times as fast as 100 ps (types 40570 through 40574).

Types 40566 through 40569 offer \( \pm 5\% \) control of peak-point current and rise times as fast as 160 ps. The rest of the family—types 40561 to 40566—offer \( \pm 10\% \) control of peak-point current and rise times in the range from 1,800 to 125 ps.

All 14 TD-II types feature RCA's unique expitaxially-grown junctions that have brought a new standard of stability, performance and reliability to tunnel diodes. Leads are gold-plated for soldering efficiency, requiring no pre-tinning. And the package configuration lends itself well to high-volume PC-board mounting operations. Circle Reader Service No. 121 for general line information.

New Design Dimension in 8-A Plastic Triacs: TA7364 Controls Up to 1,000 W, TA7365 Up to 2,000 W

Need to control ac loads in motor speed controls, heat controls, relay protection, light dimmers? Two new plastic triacs—RCA's developmental types TA7364 and TA7365—offer a number of important circuit advantages, in addition to being small, compact, flexible, and economical.

For example, exceptionally high "static" dv/dt capability gives immunity from false turn-on caused by high noise or high transient conditions found in heavy industrial environments. Increased commutating capability assures reliable operation under heavy inductive loads such as occur in motors, solenoids, and relays. And the high 100 A peak surge current capability offers important protection in applications such as inadecent lighting controls and motor start-up, where inrush currents can be many times higher than the RMS "on-state" circuit.

As a bonus, both the 200-volt TA7364 and the 400-volt TA7365 provide long-term reliability as a result of the advantages of hermeticity made possible by RCA's glass passivation of the chip. They also have low thermal resistance (2.2 °C/W junction-to-case) so you can use smaller, more economical heat sinks. And they come in a package that's so easy to mount.

We'll help you with your design problems. Circle Reader Service No. 122 for complete details.

Complement Your Power Designs with Silicon!

Design Up to 300 V Capability with RCA PNP and NPN Types

Now you can meet your product needs for complementary designs that feature high-voltage capability. Commercial, military and industrial applications needing high-speed switching or linear amplifier capabilities up to 300 V are ideal for RCA's new 2N5415 and 2N5416 units in TO-5 lead packages. Audio amplifier and industrial power switching circuits call for RCA's 2N5322 and 2N5323... "beefed up" versions of the popular 2N4036.

Check the tabulation for specifications. Then circle Reader Service No. 123 for full details.

There's more coming. Look for low-cost silicon power PNP audio devices with gain up to 1.5 A, Pd of 5 watts. Look, too, for types with \( I_c \) 5 A and Pd 45 W, and voltage handling capability up to 75 V.
"Building Blocks" for High-Performance, Low-Cost Solid-State Circuitry

RCA's PHP MAX VALUE Silicon Signal Transistors provide an unmatched combination of Performance, Hermeticity and Price for a broad range of amplifier and switching applications. Amplifier types—with prices as low as 19¢ (1,000+ quantities OEM)—let you design up to 500 MHz and beyond. They provide low-noise, high-gain, low-capacitance performance over a wide range of voltage, current and power capabilities.

Switching types, with prices as low as 24¢ (1,000+ quantities OEM), combine high-speed performance with a voltage, power and current range covering a large percentage of high-speed switching and core driving applications.

Circle Reader Service No. 124 for cross-reference directory showing 444 industry types PHP MAX VALUE transistors can replace.

"Overlay" Transistors for Small Size, Big Power Amplifier in Aircraft AM Transmitters

Here is a simple amplifier circuit—designed around RCA "overlay" transistors. Emphasis is on ease of modification, adaptation to meet many needs, ready duplication and a minimum of adjustments in operation. The basic circuit is for a broadband amplifier for AM use in the 118-136 MHz aircraft communication band. The unit operates in low-voltage, high-power Class C service—delivers up to 40 W PEP at 95% modulation from 5 mW of unmodulated input drive, and 12.5 V power supply.

RCA devices used are RCA 1N3193 axial lead silicon diodes and RCA 2N3866, 40290, 40291 and 40292 silicon n-p-n "overlay" epitaxial planar type devices.

For a detailed Application Note, circle Reader Service No. 125.

A Simple Way of Measuring the Voltage on a Capacitor Without Significantly Disturbing the Charge!

How many times have you wanted to read out the voltage on a capacitor in your circuit without disturbing the charge—or the operation of the circuit?

Here is a simple circuit-solution to the problem. It takes advantage of the high input-resistance and low input-capacitance of the RCA 3N139 MOS FET. This basic circuit may be modified in many ways to provide ultra-low (or zero) effective input-capacitance.

Circle Reader Response No. 126 for more information.

RCA CA3028A and CA3028B Integrated Circuits for Versatility and Economy in RF and IF Amplifier Designs

Here’s true versatility for your IF designs—and more! RCA CA3028A and CA3028B integrated circuits are ideal for RF and IF amplifier designs; DC, audio and sense amplifiers; commercial FM band converter designs; oscillator, mixer and limiter applications... and much more.

RCA CA3028A is usable from DC to 120 MHz—provides a power gain of 32 dB (typ.) in differential and 39 dB (typ.) in cascade at 10.7 MHz. AGC range is 62 dB (typ.) at 10.7 MHz.

RCA CA3028B offers these big extras: tight control of input offset voltage, input offset current and input bias current for the more critical design uses. At power supply level of ±12 V, input offset voltage is 5 mV (max.); input offset current, 6 µA (max.) and input bias current is 80 µA (max.). Peak-to-peak output voltage swing is 15 V (min.) with f = 1 KHz and R, of 1.6 KΩ. Circle Reader Service No. 127 for full information.

See your RCA Representative for full information on all products shown. Ask your RCA Distributor for his price and delivery. For specific data sheets, write RCA Electronic Components, Commercial Engineering, Section Q-G-11-1, Harrison, N. J. 07029.
The product improvers.

Improved N-channel FET choppers from TI feature lower capacitances for reduced feedthrough plus faster chopping and switching.

Here's the new look in FET chopper transistors from TI. A new design gives significantly lower $C_{ss}$ and $C_{rs}$.

These lower capacitances reduce feedthrough of the input signal into the output line. Faster chopping and switching are other results.

In addition to the improved 2N4856A-61A series, this family now includes 2N3970-72, 2N4091-93, and 2N4391-93 FETs, as well.

Use of any or all of these FET “product improvers” will mean big dividends for you...in upgraded performance and reduced costs.

You won't have to wait, either, because production quantities are immediately available.

So don't put off evaluation any longer. Call your TI sales engineer or distributor now. Or, for data sheets, write on your company letterhead to Texas Instruments Incorporated, P.O. Box 5012, MS 980-A Dallas, Texas 75222.

Texas Instruments Incorporated

Electronic Design 23, November 7, 1968
Now, information from your analog sensor can command machinery, automate processes, interface computers, and provide remote digital display.

How? With a Theta Decitrak system, analog information is uniquely converted to digital format. Of course, data transmission and data acquisition applications abound. Over and above these, Decitrak delivers automatic digital-control of your prime mover.

The Decitrak control system will accept commands from punched cards, tape, or manual set-points. In addition, it will introduce high/low limits and arithmetical operations into the control loop. The end result is the precision control you would expect from a custom-engineered, closed-loop servomechanism.

More than 1,000 of these systems are now in use in nuclear installations, satellite tracking stations, wind tunnels, and aboard ships. Theta can assemble a low-cost, customized system for your application from 32 basic off-the-shelf electronic modules and 27 types of shaft encoders.

Send for "Designer’s Portfolio on Decitrak" — and see how Decitrak can put your information to work!

Theta Decitrak® puts information to work
If you’re building any computer except a Computer, you need CTμL. CTμL integrated circuits will give you more speed for less money than any other ICs. They’re perfect for process control systems, test instrumentation, central processing units, computer peripheral equipment—just about anything short of an airborne computer.

Keep it in the family.
You can build a complete digital logic system with Fairchild’s family of CTμL devices. We have gates, flip-flops, inverters and memory circuits. A dozen different devices that make a computer easy to package. And, you’ll need only about 80 percent as many packages as required with TTL.

You get out of it what you put into it.
The key CTμL characteristic is nonsaturating logic. That means you get fast gate propagation delay (typically 3nsec) with slow rise and fall times (typically 6nsec). So, there’s no need for transmission lines or complex packaging. You can build an entire computer with normal two-sided circuit boards. Also, CTμL can handle signal swings as large as 3V. It also provides typical noise immunity of 500mV.

What we’ll do for an encore:
MSI CTμL will be out before the year ends. CTμL-II will be out even sooner, offering improvements like gate propagation delay of 1.5nsec. (typical, loaded) and a buffer and

The world’s largest manufacturer
inverter with propagation delays of 5nsec, compared with 12nsec in standard CTµL. And, the new MSI and CTµL-II circuitry will interface beautifully with all these standard CTµL devices:

If you want CTµL-II in sample quantities, call Fairchild. If you want standard CTµL in production quantities, call a Fairchild distributor. He has everything you need to build any computer. Even a Computer.
Who Built the Converter Used on the Army's Minigun?

Abbott did. Out of 931 converters delivered during 14 months, only two were returned for repair. Maybe that's the reason, Abbott's Model BL5D-I-1A converter was selected as a power supply for installation in the SUU-11A/A minigun system, used on helicopters in Vietnam. This system employs a 7.62 millimeter minigun pod with firing rates of 6000 rounds per minute and therefore demands high reliability. This Abbott converter has an MTBF (mean time between failures) of .129,379 hours as calculated from the MIL-HDBK-217 handbook.

Abbott power modules use only the highest quality semiconductors and MIL-T-27B transformers in their construction to obtain the high degree of reliability under tough environments demanded by today's military requirements. To withstand heat sink temperatures of 100° C all silicon semiconductors are used exclusively.

High density electronics packaging, coupled with good design, give Abbott power modules a minimum size and weight for their rated power output. One group of Abbott's DC to DC converter line, for example, the Model B05D, is smaller than a package of cigarettes, weighs less than a pound and produces five watts of regulated output voltage. All of the models described in the Abbott Catalog have correspondingly small sizes and weights.

If you have a need for a reliable converter, inverter or modular power supply, take a look at Abbott's. There are over 3000 models listed in their new catalog. They are built to operate in military environment of MIL-E-5272C at 100° C. They include output voltages from 5 volts to 10,000 volts DC with output currents from 2 milliamperes to 20 amperes. A wide range of different types of input power is available:

- 60V dc to DC, Regulated
- 400V dc to DC, Regulated
- 28 VDC to DC, Regulated
- 28 VDC to 400V, 1p or 3p
- 60V to 400V, 1p or 3p

Please write for your FREE copy of this new catalog or see EEM (1968-69 ELECTRONIC ENGINEERS MASTER Directory), Pages 1727 to 1740.
These new SAMPLE/HOLD MODULES from BURR-BROWN will help you build accurate A/D conversion systems in less time...at lower cost

Of the six Sample and Hold (or Track and Store) modules supplied by Burr-Brown, these two new units are proving to be the most popular. Why? Because they provide the type of precise, non-inverting performance that is ideally suited for highly-accurate A to D conversion systems. And, the price is reasonable. Only $110.00 for the 4034/25...$125.00 for the 4035/15...in single unit quantity.

Both units have excellent gain accuracy (+/-0.01%), low drift in the HOLD mode and a 10Mohm input impedance. Size is a convenient 1.80" x 2.40" x .60" for the Model 4034/25...only 1.20" x 1.80" x .60" for the Model 4035/15. Rack mount versions are also available.

FOR DETAILED INFORMATION on the complete line of Burr-Brown Sample/Hold Modules, simply contact your Burr-Brown Engineering Representative or use this publication's reader service card.

Operational Amplifiers Instrumentation Amplifiers Function Modules Active Filters Power Supplies

INFORMATION RETRIEVAL NUMBER 9
Help Yourself To Better Power Circuit Systems With This All-New Designer's Handbook!

Two hundred and fifty information-packed pages that will help you make the best use of the best of today's power transistors, rectifiers, thyristors and regulator diodes — with proven circuits springboarding auxiliary ideas for your future requirements!

"How-to-do-it" is the keynote. Nearly 150 breadboarded and tested designs — many of them unique and up-to-now-unpublished — point the ways to a great variety of state-of-the-art power semiconductor applications. Even for a given power system, such as dc-ac conversion multi-faceted approaches are described: low and high voltage inputs and high power outputs, 60 Hz to 15 kHz switching frequencies, unregulated and regulated output with and without overload protection and using SCR's and transistors.

Specific titled sections include:
- Motor Speed Controls
- Inverters and Converters
- Regulated Power Supplies
- Static Switching
- Servo & Audio Power Amplifiers
- Thyristor & Transistor Switches

The first of many section highlights illustrates excellent control of ac induction motors through two unique designs followed by dc motor speed controls featuring control of rotation direction, compensation for load changes and optical feedback. Other chapters are equally engrossing spotlighting series, parallel and impulse-commutated thyristor inverters; overload circuit protection with automatic reset with no series resistance to power source; triac-relays with no contact bounce or arcing; low-distortion, transformerless, load-protected power amplifiers and much, much more.

Learn the latest in power circuit designs with this invaluable technical library addition. Send for your copy today!

(To receive "Semiconductor Power Circuits," send check or money order for $2.00 payable to Motorola, Inc., to Box 20912, Phoenix, Arizona 85036.)
FEATURES:

- Wide frequency range covers 10 kHz-30 MHz.
- Measure Voltage: 1µV to 1V, f.s.d. (-118 dB to +2 dB).
- Measure Current: Clip-on current probe (optional, 0.1 — 30 MHz) 1µA to 1 A, f.s.d.
- Dynamic Range: 60 dB
- Fine Frequency Adjustment: ±2.5 kHz
- Selectable Bandwidth: 500 & 5000 Hz
- Noise Level: 0.5µV
- Input Impedances: 50, 60, 75, 150, 600Ω and 500kΩ. | 20 pF High impedance probe available.
- Internal reference makes unit self-calibrating.
- Demodulated phone output.
- Economically priced.

Price: $3085.00

Type USVH Selective Microvolt/ammeter is continuously tunable over the wide frequency range of 10 kHz to 30 MHz. High sensitivity and selectivity are outstanding features of this superheterodyne receiver with direct readings in volts and decibels. Voltage measuring range covers from 1µV to 1 V f.s.d. with an accuracy of ±3% referred to 1 MHz & 1 V. Measurements can be made to ±0.5 µV. Frequency response is ±0.5 dB from 20 kHz — 10 MHz, and ±1.0 dB from 10-20 kHz and 10-30 MHz. Type USVH also can be used for selective current measurements using Clip-On Current Probe, BN 150013. Instrument features selectable bandwidth of 500 & 5000 Hz, and provides six switchable input frequencies.

Applications Include:
- 30 MHz Wave Analyzer
- Attenuation and frequency response measurements on networks up to 140 dB
- Null indicator for high frequency bridges
- Measurements of RF distortion as low as —60 dB
- Inter-Channel cross-talk attenuation measurements on carrier systems
Add Sprague Series 7400A to your prints for Series 74N TTL circuits. They're pin-for-pin identical.

now have a phenolic terminal base

Type 7C Radial-lead Capacitors are made with alternate layers of sprayed ceramic dielectric material and screened metallic electrodes, fired into a solid homogeneous block and coated with a tough phenolic resin. Their new bossed terminal base construction provides these advantages: (1) No resin run-down on leads. (2) Uniform lead spacing is automatically maintained. (3) No dirt and moisture entrapment; degreasing fluid flows freely between capacitor and board.

Software patent debate rages despite guidelines

Can computer programs be patented? New guidelines published by the U.S. Patent Office, after several years of debate in the computer software industry, seem destined to raise more objections than they are intended to resolve.

The guidelines were announced in Washington, D.C., in a speech by Edward J. Brenner, Commissioner of Patents, before the Computers-In-Law Institute of George Washington University. They merely reaffirm in writing what has been the Patent Office's position all along:

Computer programs, as such, are not patentable. This conclusion, Brenner said, "is based on the well-established doctrine that processes which can be performed solely by mental acts do not constitute patentable subject matter."

The guidelines limit patent protection to programs that are combined with a process that alters "the form, composition, or condition of a physical substance or object."

This position of the Patent Office has stirred strong opposition among the nation's 425 software firms. Conservative estimates are that their software business will pass the $1.5 billion sales mark by 1970 and will be absorbing up to 70 per cent of the computer industry's research dollar by then. Software developers hold that patent protection is essential to the growth of their industry.

Richard C. Jones, president of Applied Data Research of Princeton, N.J., which holds the only U.S. software patent issued so far—on a sorting system—argues that current patent laws cover software "inventions." He asks that the Patent Office give software the same treatment it does hardware—that each case be considered on its own merits. Jones is confident that the courts will vindicate his position.

Referring to software as an engineering equivalent of hardware, Jones points out that in many applications, it is engineering considerations alone that dictate whether hardware or software is used to perform a given function.

But Commissioner Brenner warned in his speech that a policy of giving patents on computer programs alone would create long delays in an area where, because of rapid development, prompt action is imperative.

The issue seems likely to end up in the courts.

Lower costs foreseen for silicon devices

No significant innovations but considerable reductions in manufacturing costs are expected next year in silicon device technology.

That's the evaluation of Dr. Gordon E. Moore, vice president of Intel Corp., Mountain View, Calif. He spoke on trends at the 1968 IEEE Electron Devices Meeting in Washington, D.C.

Moore sees a move toward bigger wafers, bigger chips and greater complexity, a lower defect rate, good surface control in crystals, and an elimination of flying leads. "Little wires are on the way out," he says. "Beam-leads or flip-chips, will be adopted to achieve more reliable multiple-chip structures at lower cost."

He also sees packaging as a problem, with hermetic seals at the chip level the logical solution. "The package is a principal contributor to the cost of a circuit and has done more to down-grade semiconductor devices than anything else," he says. "Let's do away with packages and put the protection on the chip."

Moore sees dielectric films providing protection from ions and preserving surface properties in silicon devices, as well as providing mechanical and chemical protection to finished circuits. Such films are used also as insulation for multilevel interconnections and for isolation of devices in radiation-resistant circuits.

"Suitable dielectrics," Moore says, "are glass, silicon dioxide and silicon nitride. These will find increasing use in future technology.

We can use sedimentation, chemical-vapor-deposition or vacuum-deposition methods for dielectric films. Investigating the possibilities for protective films that are available to us now will keep research labs going for years."

The perfection of processes will cut manufacturing costs, Moore asserts. "Present yields definitely do not approach 100%," he notes.

He looks for two separate attacks on the low-yield problem: through direct examination of failure modes and elimination of the causes of failure, and through the use of redundancy techniques in the masking process.

"Redundancy in masking," he says, "is an important trend."

As for doping, Moore says that "we still use the same three techniques"—grown-junction and solid-state diffusion methods, and a technique in which dopants are added during epitaxial growth.

"These techniques are powerful," he says, "and offer good control of impurity patterns. We can build almost any three-dimensional structure that we desire, and although we may employ many more steps, the processes are the same as they were a few years ago."

Who's who, what's what in data-processing field?

In the last decade there's been a small population explosion in the world of data processing. Who are the people in this mushrooming field? What do they do? How much money do they make?

The questions are expected to be answered in a comprehensive report, "Survey of Information Processing Personnel," which is being compiled by the American Federa-
news

Electroacoustic amplifier has separate elements

A new type of traveling-wave electroacoustic amplifier that uses mutually coupled piezoelectric and semiconductor materials has been developed at the General Telephone and Electronics Laboratories, Inc., Bayside, N.Y.

As developed by Stephen Yando, senior engineering specialist, and Dr. Chava Fischler, research engineer, a wafer of silicon is bonded to a wafer of lead zirconate titanate—a piezoelectric material. Acoustic waves are launched in the piezoelectric wafer, and a parallel current of drifting carriers is set up in the close-coupled silicon wafer. Amplification takes place when the carrier drift velocity exceeds the traveling-wave velocity, and energy is transferred from the carriers to the wave.

Because the new amplifier has separate semiconductor and piezoelectric elements, it can be designed with more flexibility than older, single-crystal types which were made from a semiconductor with piezoelectric properties. Where, up to now, the designer has been locked in by the properties of the single-crystal material, with the GT&E amplifier approach the designer is free to choose materials independently of each other.

The GT&E device has reportedly achieved gains of 12 dB/cm over octave bandwidths in the range of 0.5 to 4.0 MHz. Although noise-figure measurements have not, as yet, been made, the experimenters report that their signals appear to be much cleaner than those achieved with single-material amplifiers.

Approximately 0.5 watt of output power has been obtained so far. The researchers explain that no attempt has been made to maximize power output.

The work was described at the International Electron Devices Meeting in Washington, D.C.

U.S. to award contracts for computer interfaces

Bid proposals to build interface message processors (Imps) for a computer network for the Defense Dept.'s Advanced Research Project Agency have been narrowed down to a few. The contract winner should be announced in a few weeks.

Imps, which will be made of modified off-the-shelf equipment, are needed because many of the 35 computers at 19 sites in the U.S. don't speak a common language. Digital computers themselves, the interface message processors will translate each computer's output into one standard code for communications and display. And, when necessary, they will translate the language of one computer into the language of another.

The defense agency plans to use the network to exchange research and development information and to test new techniques for tying together military command and control networks.

Spaceborne instrument may monitor pollution

Polluted air in the earth's atmosphere may soon be monitored and measured by a new instrument—the correlation spectrometer—that will look down from space orbit.

The feasibility of monitoring, by satellite, the movement and dispersion of masses of polluted air has been demonstrated, according to the developer, Dr. A. R. Barringer, president of Barringer Research, Rexdale, Ontario.

Speaking at the 23rd annual conference of the Instrument Society of America, the Canadian researcher cited results of measurements made during airplane flights over a dozen U.S. and Canadian cities earlier this year. These results, he maintains, demonstrated the practicality of making similar measurements from orbiting satellites.

The measuring technique, he devised, employs the characteristic spectra or "signatures" of specific pollutants which appear in the visible and near visible wavelength regions.

The Barringer Correlation Spectrometer views the atmosphere through reflected sunlight, which is dispersed by a grating onto a photographic mask. Since the mask is a photographic replica of the pollutants being sought, only light identical to that imprinted on the mask is registered. The amount of light thus passed gives a measure of the contamination present. Resolution of the measurement amounts to a few parts in a billion.

Financial support for the new development has been provided by the National Aeronautics and Space Administration and the Department of Health, Education, and Welfare.

Photomultiplier accuracy raised tenfold by RCA

A photomultiplier amplifying stage that is 10 times more efficient than previous models has been developed by RCA's Industrial Tube Div., Lancaster, Pa. The new light detector, the company says, counts the electron input inaccurately enough "to revolutionize studies of the DNA molecule, detect light from radio stars and show how green plants convert sunlight into food.

The amplifier's dynode is coated with a gallium phosphide layer that emits approximately 30 electrons for each one that reaches it from the photomultiplier. This ratio is large enough to overcome possible errors that arise when initial electron entry is counted with conventional photomultiplier materials; the latter emit electrons at the rate of only 5 or 6 to 1.

The dynode's gallium phosphide layer is deposited from hot vapors by a process known as "vapor phase growth."
How to use a Singer Model SPA-100 Microwave Spectrum Analyzer to measure close-in noise

Measuring close-in noise (noise that is close to the carrier) has always been a vital part of many laboratory and production-line tests. But today's solid state oscillators, so much noisier than klystrons or tubes, make the accurate, simple and fast measurement of close-in noise crucial to the successful operation of many systems. The Singer Model SPA-100 microwave spectrum analyzer replaces the complex microwave discriminator systems formerly required to make this measurement.

1. This measurement of noise (noise whose amplitude is inversely proportional to the frequency separation from the carrier per unit of bandwidth) can be clearly seen on the analyzer's screen as 47 dB down from the carrier. The analyzer settings for this measurement were fixed at a bandwidth of 3 kHz and a dispersion of 100 kHz per division on the CRT graticule. The noise level at any other frequency is easily scaled from the display.

The simplicity of its operation makes the Singer Model SPA-100 ideally suited for the measurement of close-in noise. It has six calibrated bandwidths and a virtually noise-free triode first local oscillator. Its excellent sensitivity provides the wide dynamic range necessary for these measurements as indicated:

<table>
<thead>
<tr>
<th>Signal Frequency (GHz)</th>
<th>Calibrated Bandwidth Setting (kHz)</th>
<th>Maximum Dynamic Range (dB)</th>
</tr>
</thead>
<tbody>
<tr>

<td>1</td>
<td>80</td>
</tr>
<tr>
<td>3.2 - 11</td>
<td>100</td>
<td>60</td>
</tr>
</tbody>
</table>

Sharp skirt selectivity allows signals close to the carrier to remain unmasked and easily visible. For example, in the 1 kHz bandwidth mode, signals as close as 25 kHz away from the carrier, 60 dB down may be measured. Similarly, using 100 kHz of bandwidth, signals 175 kHz away from the carrier, 60 dB down, may also be measured.

A detailed application/data bulletin on the Model SPA-100 is now available. The bulletin covers many of the principles of microwave spectrum analysis. For your copy, use the Readers Service Card, or write on your letterhead.

2. White noise (noise whose amplitude is constant with the frequency separation from the carrier per unit of bandwidth) is often measured by the Singer Model SPA-100 spectrum analyzer. Here, with the analyzer set at a bandwidth of 3 kHz and a dispersion of 100 kHz per division, the white noise is visible at 59 dB down, 150 kHz away from the carrier.

The Singer Company, Metrics Div., 915 Pembroke Street, Bridgeport, Conn. 06608 (203) 366-3201

INFORMATION RETRIEVAL NUMBER 14
If flat time delay is a requirement in your FM communications or radar system, specify the Damon line of Gaussian Crystal Filters. For example, in a coherent pulsed radar system, the Damon Model 5750A can minimize return-pulse overshoot. And its well-behaved impulse response can reduce ringing in frequency scanning applications. In an FM application, the versatile 5750A provides 4-pole selectivity with a linear phase characteristic to eliminate delay distortion.

Model 5750A Specifications: Center frequency (f): 10.240 MHz ± .005%. Bandwidth at 3 db: 10 KHz nominal. Selectivity: 4-pole Gaussian approximation. Pulse response: ringing at least 25 db below main response, with input pulse of 100 microseconds at nominal f. Source and load impedance: 95 ohms. Insertion loss: 3 db max. Operating temperature: 0° to +55° C.

Whatever your signal-shaping needs...from a uniformly rounded Gaussian curve to a sharp rejection notch...rely on the form-factor specialists at Damon. Write: Electronics Division, Damon Engineering, Inc., 115 Fourth Ave., Needham, Mass. 02194, or call (617) 449-0800.
Thick-film, thin-film and monolithic approaches call for trade-offs by the microwave circuit designer

Michael J. Riezenman
Technical Editor

Knowledgeable designers are no longer asking whether microwave integrated circuits (MICs) are the wave of the future. The big question today is: "How should I make them?"

There are three major approaches in MIC design: thick-film, thin-film and monolithic. Each technique has advantages and limitations, and the designer must trade off such considerations as resolution, cost of fabrication and the number of circuits needed in deciding which approach to use.

This week NEREM 68—the IEEE Northeast Electronics Research and Engineering Meeting—is devoting an entire session in Boston to a discussion of the various fabrication techniques.

Thick films offer low cost

The thick-film circuits are the easiest to manufacture, says Tom M. Hyltin, manager of microwave circuits at Texas Instruments, Dallas, and chairman of the NEREM session (No. 15) in the Sheraton-Boston Hotel. Thick films require the least expensive equipment for fabrication, and they have the lowest cost per square inch of circuitry, according to Hyltin.

Monolithic circuits, he says, are without question the most difficult form of microwave circuitry to make, and they require the most expensive manufacturing equipment.

Thin-film circuits fall between these two extremes.

Why then use anything but thick-film MICs? The answer is resolution. Most MICs are constructed with a microstrip geometry (see box). In this configuration, the line impedance is strongly dependent on the width of the line and the thickness of the dielectric substrate. Hence, in applications where it is important that the line impedance not vary, it becomes necessary to control the line width very closely.

Similarly the lengths of the transmission lines must be controlled to within small fractions of a wavelength, since the phase shift that they introduce is usually a carefully calculated quantity in the design of the circuit. At X-band, for example, on an alumina substrate, the phase shift is 1 degree per mil.

Good resolution is also needed to allow the fabrication of very small lumped circuit elements; this increases the density of circuits per unit area of substrate surface and thus lowers the cost per circuit.

Monolithic circuits offer the best resolution and thick-film circuits the worst. However, thick-film technology is still good enough for many applications, and efforts are under way to improve the resolution.

But monolithic circuits, in which a semiconductor is used as the substrate, are not really serious contenders at frequencies below about 10 GHz. There are two significant reasons for this: (1) Microstrip transmission lines made with a semiconducting substrate are too lossy to be used at frequencies where the lines are at all appreciably long (see Fig. 1), and (2) The large areas of substrate material that are required at the lower microwave frequencies make the cost of the semiconductor prohibitively high.

Hence, below X-band the choice is really between thin-film and...
thick-film circuits. The terms "thin" and "thick" are actually somewhat misleading, says Dr. Martin Caulton, a member of the technical staff of RCA Laboratories, Princeton, N.J. The thickness of the films used in MICs is determined by skin-depth considerations, and the depth is approximately the same in both technologies. Caulton, who is presenting the thin-film paper at NEREM, pointed out that the metal films should be a few skin-depths deep to avoid excessive losses. Typically, he said, line thicknesses of 5 microns (0.2 mil) are used at 2 to 3 GHz and 3 microns at X-band. This is of the same order of magnitude as the 0.5-mil thickness that has become almost standard in the thick-film method. A more meaningful way to distinguish between thick-and thin-film circuits is suggested by Raymond K. Barcklow Jr., a member of the technical staff of ITT-Defense Communications, Nutley, N.J. Consider the way the two films are made, he says: The thin-film process is one of vacuum deposition by techniques such as evaporation and sputtering, whereas thick-film circuits are made by less exotic processes such as screen printing and spraying.

This difference is responsible for the differences in cost and resolution between the processes.

Thick films and thick inks

There are two competitive methods for fabricating thick-film circuits: screen printing and etching. In the etched approach (Fig. 2), you form a layer of metal on a dielectric substrate, such as alumina, by applying a metal solution to the substrate and firing it. The pattern on one side of the ceramic is left intact and serves as a ground plane, while the other side is etched with photolithographic techniques to form a pattern of conducting lines. These lines are then plated with gold, and uncased semiconductor chip devices can then be bonded to the conductors to form completed circuits.

The chief disadvantage of this technique is the large number of steps required to form multi-layer components, such as capacitors. Each layer of metal or dielectric must be applied, fired, masked and etched. This raises the cost above that of the competitive printed approach in which the layers are screened onto the substrate one at a time and fired individually. The etched approach does afford somewhat better resolution than the printed approach, however.

In an effort to investigate the limitations of the printed approach, Charles Greenwald, manager of advanced R&D, ITT-Defense Communications, along with Barcklow and E. Zaratkiewic of the ITT-Avionics Div., has been building experimental circuits with the screenprinting technique. He reports that circuits operating through X-band have been successfully constructed.

To build their relatively high-resolution, screen-printed circuits, the ITT group is employing a combination of techniques to improve the resolution of the thick-film printing process. These include the use of very fine-mesh screens, thixotropic inks and slow air-drying of the patterns. The present work uses 325 mesh screens (325 lines per inch). The conductors are made from DuPont No. 8115 gold ink with a viscosity of 1000 poise. Although it has a resistivity of 0.005 ohms per square, the gold ink is preferable to silver, with 0.001 ohm per square resistivity, because of its superior printing properties. The gold ink is thixotropic, which means that it doesn't flow unless it is subjected to shear forces. This improves pattern resolution, since the ink doesn't spread after printing. After the patterns are deposited, they are dried slowly in
Design in precise solid-state temperature sensing

...now for just pennies

Ice maker control circuit courtesy of Gibson Refrigerator Div.

Carborundum®
Negative Temperature Coefficient Thermistors with resistance tolerances to ±5% are now available for as little as 5c per unit.

Our new automated thermistor production line means greater savings, tighter control of tolerances, for every NTC application.

Now you get greater sensitivity at economy prices—choose from five alpha values ranging, for example, from -5.0%/°C to -7.2%/°C at -10°C.

This sensitivity means a large signal change for small temperature change.

In this ice cube maker control circuit, an NTC thermistor senses the change from cold water to ice, which is frozen dry. As temperature drops, resistance across the thermistor increases. At the required temperature, the thermistor activates the unit's ice cube harvest/refill cycle. A second thermistor compensates the reed relay for ambient-temperature changes.

You too can simplify circuit design, cut costs, and improve temperature-sensing reliability in your solid-state design with Carborundum NTC thermistors.

For detailed information, or assistance on specific applications, write to Mr. James Battle, The Carborundum Company, Electronics Plant, Niagara Falls, N.Y. 14302.

Precisely yours...
The big advantages of this technique, according to Greenwald and Barcklow, are its economy and flexibility. The process is simple and inexpensive because it consists of only two basic steps: printing and firing. Conductive inks, resistive inks, high-dielectric-constant inks and encapsulating inks are all available and are simply screened onto the substrate in the appropriate order to form various devices. Since the process does not have very high resolution, some trimming is needed; but this is done automatically and doesn't add greatly to the cost (see Fig. 3). In the manufacture of capacitors, a barium titanate-based ink with a relative dielectric constant of 1600 is screened over a metal film and topped with another metal film. The high dielectric constant means that the dielectric layer can be quite thick and the breakdown voltage correspondingly high. Capacitors with 10,000 pF per square inch and 500-V breakdown have been made this way.

If very high capacitance is not needed, titania (TiO₂) can be used with some improvement in temperature stability.

Flexibility is provided by the wide range of values that can be produced in such components as resistors and capacitors. Resistive inks, for example, are available that vary in resistivity from 1 ohm per square to more than 10-k ohms per square. This can be contrasted with the thin-film approach, in which the choice of resistive materials is limited by their compatibility with a vacuum-deposition technique.

However, as Greenwald and Barcklow are careful to point out, thin-film resistors have much lower temperature coefficients than the most stable inks, although the inks are steadily improving (see "Thick films headed for wide use in the 1970s," ED 16, Aug. 1, 1968, pp 25-32). A more important advantage of the thin-film approach is the extremely fine resolution that it provides. Caulton has fabricated lines 6 microns (0.24 mils) wide with a spacing of 6 microns, whereas thick-film technology is limited to line widths of about 2 mils and spacings of about 1 mil. Alexander T. Botka, head of IC development at Microwave Associates, Burlington, Mass., who is a co-author of the NEREl paper on etched thick-film circuits, points out that it is easier to make a narrow gap between two lines than to make a narrow line. The reason is undercutting. As seen in Fig. 4, undercutting is a problem with etched circuits because the etching solution attacks the sides of the conductors as it forms them. As a rule of thumb, the amount of undercut is about equal to the thickness of the metal. Hence, Botka says, if you try to make a very narrow line out of fairly thick material, it will fall off the substrate.

The problem of undercutting is not limited to the thick-film makers, since, as pointed out earlier, the thin films used in MIC work are actually quite thick. A partial solution to the problem—one being used in thin-film fabrication (Fig. 4)—is to deposit and etch very thin films and then, after the pattern is defined, to plate the required thickness of metal onto the pattern. This would seem to solve everything, but it does not. Caulton explains that the plated metal, unfortunately, does not always have the smoothness and conductivity of the bulk metal. Therefore it can be more lossy. Hence, in considering whether to etch the rather thick thin-films or use the plating and etching technique, the fabricator must weigh the relative importance of lossiness of the line and accuracy of its definition.

In the construction of coupled circuits, for example, it may be necessary to have line separations of less than one mil. This requires the plating and etching technique. On the other hand, a 50-ohm line on 20-mil alumina is 19 mils wide (see box). Here the etching uncertainty of, say, 0.3 mils is no problem, and the lower-loss etching method can be used.

**Lumped elements save space**

Traditionally the microwave circuitry is fabricated with distributed passive elements. But, as
For a paltry $38* each you can get a complete read-only memory system on a chip (made to your specs and delivered 4 weeks from next Tues.)

*Buy a hundred of the MM520 commercial version at $38 each.
Or, better yet, buy more.

Caulton points out, at the lower microwave frequencies, distributed circuits take up a great deal of area, and the use of lumped elements—if they can be made small enough and with sufficiently high Qs—is worthy of exploration. In fact, the only reason for using distributed elements in the first place is the difficulty in making miniature lumped elements. This point is recognized by Montgomery, Dicke and Purcell in a classic book in which they note that the difficulties of fabricating small, high-Q components call for using distributed techniques.

But, Caulton points out, modern photolithographic techniques have removed many of the objections to the lumped approach, and it must be reconsidered in the light of present knowledge.

Caulton and his colleagues at RCA Laboratories have built and tested 2-GHz, lumped-element, thin-film transistor amplifiers with single-stage gains of 13 dB at low power levels and 4 dB at 1 watt. Cascaded operation provided more than 17 dB of gain at 0.8 watts cw.

At L- and S-bands, the savings in substrate area that can be realized by using lumped elements is on the order of 10:1. This means that the amplifiers or other microwave circuits that can be put on one substrate can be increased about ten times. Now, since the cost of integrated circuits varies inversely with the number of circuits processed at one time, the size reduction has important economic significance. As frequency goes up, the size of the distributed circuits goes down, and the advantages of the lumped approach disappear.

In building lumped-element microwave ICs, the designer must keep the Qs of the inductors and capacitors as high as possible, to keep losses down to a level comparable to those achieved with distributed-element circuits.

Problems with monolithics

The monolithic MIC, in which the substrate serves both as an active semiconductor and a transmission line dielectric, represents the ultimate in line resolution and circuit reproducibility. But it also presents some very difficult fabrication problems. As is evident from Fig. 1, the ohmic losses of microstrip transmission lines with semiconducting substrates are too high to permit reasonable performance below X-band. Above those frequencies, acceptably low losses can be obtained with high-resistivity semiconductors.

However, Frank E. Emery of Texas Instruments, who is presenting the NEREM paper on monolithics, points out that at the higher frequencies great care is needed in circuit design to prevent surface-wave propagation. To avoid this problem, he says, the transverse dimensions of the microstrip must not be allowed to approach a quarter wavelength. This necessitates the use of thinner substrates and narrower lines than at the lower microwave frequencies.

The most important problem is that posed by impurities. Microwave ICs use a much higher resistivity, and hence a much purer semiconductor, than do ordinary ICs. To maintain the high-resistivity substrate characteristics while depositing impurities onto selected areas of the chip requires extreme care and special procedures. Hyltin cites the use of different oxides and diffusion temperatures as two of the steps taken to lessen the probability of picking up impurities.

If the problems are so great, why use monolithic MICs? First of all, says Hyltin, silicon has an amazingly fixed dielectric constant. It is essentially unchanged over wide ranges of temperature and over the whole microwave frequency spectrum. This means that narrowband filters built on silicon will be very reproducible and stable. No trimming should be needed in their manufacture, and no changes should occur in the field.

A second advantage of silicon, Hyltin notes, is its high thermal conductivity. This allows it to handle much higher powers than other materials. A switching diode built into a silicon substrate, for example, could handle much more power than a similar diode mounted on alumina, Hyltin says.

Nose-cone antenna aids ionospheric research

A four-frequency, omnidirectional antenna system, used to measure the effect of electron densities on rf propagation in the ionosphere, fits into a rocket nose cone that is only 43 inches long and 9 inches wide at the base.

The unique assembly, which weighs just under 14 pounds, has been used in Nike-Javelin III and other rocket flights from NASA's Wallops Island launching area in Virginia and from Eglin Air Force Base, Fla. While the Army has not disclosed the reasons for its ionospheric study, technical observers believe that it is in support of the development of the Sentinel antiballistic missile system.

The area of interest in the upper atmosphere, according to an Army spokesman, begins at 50 kilometers and extends to 640. Thus, data are being radioed, via four Army-furnished beacon transmitters, through the E- and F-layers of the ionosphere as the rockets ascend and descend.

Two major design problems

The antenna system, designed and built by the Orlando, Fla., division of Martin Marietta Corp., overcame two major design problems: the limited volume available within the nose cone of the rocket and the operational requirement for an acceptable antenna pattern from the rear of the rocket.

The minimum acceptable antenna pattern called for uniform coverage within a 90° pattern off the rocket tail and centered about its longitudinal axis. Uniform coverage was defined to mean a maximum of ±1 dB variation. Because rocket-motor burnout occurs at approximately 20 kilometers and the measurements were to begin at 50 kilometers, transmission to Earth through the rocket plume was not a design problem.

Joseph C. Pullara, the staff engineer at Martin-Orlando who designed the antenna, describes it as a four-frequency, continuous-wave, phase-coherent system. Measurements, he says, are made by comparing the phase of a low-frequency carrier with the phase of a much higher frequency. The basis of this technique is that the low-frequency carrier is strongly affected by an ionized medium, while phase at the higher frequency is comparatively unaffected. Thus a “dispersive-Doppler” measurement is obtained by determining the phase difference at any given point throughout the rocket flight.

The four frequencies are 37, 74, 148 and 592 MHz, each harmonically related. The 74-MHz signal, Pullara discloses, is employed for propagation-attenuation measurements only, while the three others are carrier frequencies required for the Doppler measurements.

A range of sensitivity

The most sensitive and accurate measurement, Pullara reports, is between the 37- and 148-MHz signals. But, he points out, the dynamic range at 37 MHz is limited by high attenuation. The converse is true with measurements that compare the 148-MHz signal with that at 592 MHz.

In his antenna design, a 37-MHz loop is mounted orthogonally with a 74-MHz loop; the 148-MHz, folded-back dipole is mounted orthogonally to a 592-MHz, folded-back dipole. The loop subassembly is oriented at a 45-degree angle with respect to the folded-back subassembly. The whole assembly is such that feedpoints are colinear with the longitudinal axis of the radiosounding rocket.

The two lower-frequency antennas, Pullara discloses, were designed as electrically small loops, since earlier study had shown this approach to provide the most efficient radiators for the particular application. Identical except for size, the two lower-frequency antennas are made of a brass strip, 1/8 inch thick by 1 inch wide and tapered to fit the nose-cone ogive. The loop is fed across a balanced transformer, and a shunt variable capacitor tunes out antenna reactance.

The 148-MHz antenna is described by Pullara as “simply a folded-back dipole.” The radiation pattern produced by such a configuration is very nearly isotropic, he asserts, since the swept-back dipole arms negate the effect that normally produces a null in the E-plane of a straight half-wavelength dipole. In this instance, reactance compensation is handled by an externally tuned capacitor (reactance is produced when the arms are folded back at a sharp angle).

No tuning required

The two upper-frequency antenna designs are nearly identical, except that the swept-back angle of the 592-MHz radiator is shallower. As a result, it responds electronically more like a half-wavelength dipole and exhibits no high-reactive impedance components, and it requires no tuning to meet bandwidth needs, Pullara says.

He emphasizes that the antenna does not compensate for spinning or precessing phase changes. Rather, it provides only uniform phase and amplitude coverage and pure linear polarization, thus significantly reducing phase variations caused by precessing. Phase variations resulting from rocket spin are periodic. These, says Pullara, can be subtracted from the data by receiving the linearly polarized signals through two oppositely sensed, circularly polarized antennas and, then, by processing the signals in such a manner as to leave only phase changes caused by Doppler shift.

Pullara emphasizes that the dispersive-Doppler technique is only one of several available electron-density measurement techniques. However, the approach was applied to the Army problem because it lends itself readily to the performance of attenuation measurements and still provides an extended range of electron-density measurements within a single electronic package.

Procurement was recently completed with delivery of a total of 22 systems, the Army says. ■■
Solve your noise problems with circuit modules.

We told you in the past how our circuit modules reduce noise. Now we've improved them even further.

An additional reduction in noise figures of from 30 to 50 percent has been obtained by circuit improvements in Sylvania's popular line of circuit modules. The 13 new modules added to the line are completely compatible with previous units.

The key to improved noise reduction is the addition of a leadless low-inductance capacitor between the power and ground planes. This improvement is in addition to the already low noise figure of our circuit card that is achieved by

its unique construction and inherent low noise of Sylvania’s SUHL integrated circuits.

Until the development of our circuit modules you couldn’t take full advantage of the speed capability of our SUHL II 50-MHz logic. Noise levels limited practical operation to speeds of about 20 MHz. Now you can approach the full 50-MHz capability of these devices when you buy them on our circuit boards.

The circuit module is made up of two four-layer boards mounted on either side of an aluminum “backbone.” Each board has two signal planes plus distributed power and ground planes. When necessary, the signal planes can be electrically interconnected with plated-through holes. The distributed power and ground plane construction allows every IC lead on the board to be within 1/64” of the power and ground planes. The result is extremely short lead lengths and, thus, low noise pickup.

Typical of the new circuit boards is our #262 memory card and #263 memory select driver. Here, we’ve done your memory design work for you. The #262 is a 128 bit card (2 bits x 64 words). Combined with the #263 memory driver, it gives you a sophisticated system-oriented building block that can solve your memory problems with a minimum of interconnections.

CIRCLE NUMBER 300

New CRT brightens picture for air controllers.

Scan conversion system using Sylvania CRT makes airport tower radar displays visible in bright sunlight.

Airport towers, where lighting conditions can vary from darkness to 4,000 foot-candles, put tough demands on the contrast and brightness of radar displays.

As a result of considerable research and development work within the Federal Aviation Administration, bright radar displays for use by air traffic controllers have become a reality. Based on an FAA-issued specification, ITT Industrial Laboratories, Fort Wayne, Indiana has come up with an optical scan conversion system that solves the problem for FAA flight controllers. The system uses a special long-lag vidicon camera optically coupled to a Sylvania 5-inch CRT to convert the PPI radar display into a high-brightness 945-line TV display.

The high-resolution requirements put a stringent demand on the CRT used in the conversion process. To meet the need, Sylvania developed the SC-5014P31. This tube provides a 0.0015-inch line width on a 5-inch optically flat faceplate. The neutral gray non-browning faceplate is designed to give optimum photographic quality. Brightness is enhanced by the use of an aluminized screen.

In operation the PPI unit in the diagram accepts the normal radar inputs and displays the radar video on the face of the Sylvania CRT. The vidicon camera is focused on the CRT display and converts it to a uniform bright TV display. The long-lag photoconductive surface of the vidicon retains images of moving aircraft so that a minimum of five trails are visible to indicate direction of movement.

The composite EIA video signal is fed to a special 12-inch CRT for viewing by the flight controller. The display has a highlight brightness of up to 500 foot-lamberts giving the controller an acceptable display in the tower at any time of the day or night.

It is in applications like this, where the demands on CRTs are exacting, that Sylvania’s experience and technical know-how really pay off.

CIRCLE NUMBER 301
A spark gap represents an almost ideal device for the job of protecting equipment against voltage surges. Under normal load conditions it presents a very high impedance (100 megohms). If a surge occurs, the gap breaks down and appears as a virtual short circuit. When the overvoltage drops below the extinguishing voltage of the gap, the device immediately returns to the high impedance state.

Sylvania's SG-1361 argon-filled spark gap is a miniature unit designed to protect low power components such as relays, capacitors, coils, and active devices from overloads. It has a nominal firing voltage of 600 V at 60 Hz and a firing voltage range of 500 to 900 V, 60 Hz. Maximum firing current is 25 mA.

The SG-1361 can be used with higher energy circuits if a series resistor is used to reduce the amount of energy transferred by the spark gap to ground. When used as a secondary protector, along with a primary surge arrestor, the SG-1361 can protect components against lightning strikes and other high-transient overloads.

Its small size (3/4-inch long and 0.215-inch in diameter) and its simple economical construction make the SG-1361 an easy component to fit into any system. Since it comes with pretinned Dumet leads the device can be wired directly into the circuit without the use of adapters or clip-type holders.

CIRCLE NUMBER 302
How to design with the SA-20 wideband amplifier.

Sylvania's SA-20 is a versatile general-purpose wideband amplifier. Its characteristics include a high gain-bandwidth product, large signal swing and excellent linearity.

The SA-20 has three direct-coupled NPN transistors in a single-ended configuration. Bias for the input transistor is established internally by divider \( R_1 \) and \( R_2 \) (Fig. 1). Zener diode \( D_2 \) raises the bias level of \( Q_2 \) to permit operation of \( Q_1 \) in the linear range. Emitter follower \( Q_3 \) buffers the output load circuit from the intermediate stage, \( Q_2 \), thereby giving a higher total open-loop circuit gain even with low-value loads. Series DC negative voltage feedback is applied from the output of the emitter follower to the emitter of \( Q_1 \) by divider \( R_4 \) and \( R_6 \).

The major power supply current path is through the output transistor, \( Q_3 \). Total device current drain is therefore strongly related to the quiescent output voltage and the value of \( R_6 \). The output transistor has a maximum current capability of 50 mA. Maximum junction and case temperature for the device are 200°C and 155°C, respectively. Worst-case thermal gradients of the dual inline package used for the SA-20 are \( \theta_{JA} = 0.15°C/mW \) and \( \theta_{JC} = 0.075°C/mW \).

In most instances the base current of the input tran-
Resistor is small relative to the current in the input divider. Under these conditions input quiescent voltage is:

\[ V_{\text{Qin}} = \frac{(V_{\text{cc}}R_2)}{(R_1 + R_2)} \]

Bias level of the input transistor may be varied by shunting resistors \( R_1 \) or \( R_2 \). However, consideration must be given to the effect of a change in \( V_{\text{Qin}} \) on such factors as current drain and output quiescent voltage.

The output quiescent voltage, \( V_{\text{Qout}} \), is:

\[ V_{\text{Qout}} = R_4 + R_1 \left( \frac{V_{\text{cc}}R_2}{(R_1 + R_2)} - V_{\text{BE}} \right) \]

\( V_{\text{Qout}} \) can thus be changed by external resistive shunting of any of the four resistors in the expression.

The maximum voltage swing of the device with an \( R_L = \infty \) is essentially a function of the supply voltage and the zener-diode voltage. In the positive direction the voltage is limited by the voltage drop across \( R_3 \) and the base-emitter voltage of \( Q_3 \). The voltage swing in the negative direction is limited by the zener voltage plus the saturation voltage of \( Q_3 \) minus the junction drop of \( Q_3 \). With a high \( R_L \) the device will normally swing between 22.5 V and 6.5 V. If the quiescent output voltage is at the optimum level of 14.5 volts, the AC swing at the output, assuming negligible resistive loading, is approximately ±8.0 V.

Current restrictions limit the maximum possible voltage swing when using AC-coupled resistive loads of more than approximately 600 ohms.

In the case, when \( R_L \) is low, the maximum output voltage is

\[ e_{\text{o max}} = V_{\text{cc}} - V_{\text{BB}} + \frac{(R_3V_{\text{Qout}})}{(\beta_3+1)(R_2)} \]

Assuming a typical device with \( V_{\text{cc}} = 24 \text{ V} \), an AC-coupled 50-ohm load and \( \beta_3 = 100 \) which is normally the case, the maximum absolute voltage level as seen at the emitter of \( Q_3 \) is \( e_{\text{o max}} = 16 \text{ V} \).

The maximum positive swing as seen at the load is therefore 1.5 V. The negative-going swing from the quiescent voltage level is a function of the quiescent current of the device. In terms of absolute voltage the minimum output voltage, \( e_{\text{o min}} \), of the device with low value of AC coupled load is:

\[ e_{\text{o min}} = V_{\text{Qout}} - \frac{(V_{\text{Qin}}-V_{\text{BE}})}{R_0} R_L \]

Again, assuming a typical device and AC-coupled load of 50 ohms, \( e_{\text{o min}} = 14.5 - 0.675 = 13.8 \text{ V} \).

The maximum linear swing with an AC coupled 50-ohm load is therefore 1.5 V above and 0.67 V below the quiescent voltage.

It is possible to increase the swing capability of the device in the negative-going direction when driving low-resistance loads by increasing the quiescent current. This may be accomplished by a DC resistive load or current source. A 1000-ohm DC resistive load increases the negative-going voltage swing across an AC-coupled load from 0.67 V to 0.67 + [((14.5 V) 50 / 1000)] or 1.4 V. Thus the swing can be made symmetrical.

The three-stage open-loop gain of the SA-20 is about 900. Closed-loop voltage gain is:

\[ A_{\text{VCL}} = \frac{A_{\text{VOL}}}{1+\frac{A_{\text{VOL}}}{\beta}} \]

where \( \beta = R_4/(R_4+R_6) \).

Resistors, \( R_4 \) and \( R_6 \) are 100 and 1000 ohms, respectively. Since the quantity \( A_{\text{VOL}} \beta \) at low and medium frequencies is significantly greater than 1, the expression for closed-loop gain simplifies to \( A_{\text{VCL}} = 1/\beta = 11 \). By shunting \( R_4 \) or \( R_6 \) with an external resistor, the gain of the circuit can be varied. However, as shown previously, other characteristics such as \( V_{\text{Qout}} \) and associated parameters are also changed by padding either of these resistors.

To change the mid-frequency gain without affecting the quiescent level, it is necessary to shunt the internal resistor with a series RC network.

To maintain AC stability a shunt-type feedback loop using an external capacitor is required between the base and collector of \( Q_2 \). Phase margin of a typical device is >45° when the feedback capacitor is 3.6 pF.

The SA-20, when connected in the standard configuration, as shown in Fig. 2, exhibits the characteristics shown in Fig. 3. It can be seen that by varying the value of the shunt-feedback capacitor, \( C_L \), the bandwidth of the device can be varied considerably.

In the maximum-gain configuration shown in Fig. 4, AC series feedback is removed from the circuit by shunting \( R_4 \) with a capacitor. With the device connected in this manner, the shunt-feedback capacitor which is normally connected between pin 1 and pin 2 is not required. The gain of the amplifier with all forms of AC feedback removed, is about 60 dB up to 5 MHz. From 5 MHz to 100 MHz, the amplifier rolls off at an average rate of ~8 dB/octave.

In the selective-amplifier configuration of Fig. 5, the circuit functions as bandpass and notch amplifiers. Series or parallel tuned circuits are used in the shunt feedback loop to achieve the desired response.
For short pulse detection: try back diodes.

Microwave designers have a wide choice of devices when it comes to video detectors. Few of these choices, however, have all of the advantages of back diodes when it comes to short-pulse response and fidelity. Among the features of back diodes are high sensitivity, low video impedance and low 1/f noise.

Sylvania's new planar germanium back diodes have all of these features plus a few others including high reliability, and improved temperature stability.

Typical values of tangential signal sensitivity range from $-56\, \text{dBm}$ (10 MHz video bandwidth) at L-band to $-50\, \text{dBm}$ at X-band. Low video impedance is a unique feature of back diodes and it is obtained without the use of any noise-generating DC bias. Impedance values in the hundreds of ohms range are commonly obtained, and in some cases can be as low as 100 ohms. Impedance levels like these mean shorter time constants in the video output circuit, which in turn means better pulse fidelity. Noise figure is another area where back diodes shine. Even where a substantial self-bias current or a DC bias is a must, 1/f noise is minimal thanks to the low resistance and inherent physical qualities of the device.

In Sylvania back diodes, ruggedness and reliability are assured by the use of bonded, brazed and welded construction. The Sylvania diodes are available in the 048 pill package that is ideal for stripline circuitry. They are also available in other package configurations or in chip form.

Electroluminescent clocks will time Apollo flights.

A total of 46 electronic clocks have been designed and built by Sylvania Electronic Systems for use in upcoming Apollo missions. The clocks display hours, minutes, and seconds on a 2 x 4½ inch electroluminescent display panel. Two clocks are used in each Apollo command module and one is used in the lunar excursion module.

Electroluminescent readouts were selected for a number of reasons: they are not prone to catastrophic failure, they give off almost no heat and require much less power than conventional light sources. Since the EL readout is a planar display there are no parallax problems when viewed from an angle.

The clocks used in the command module are used to keep a record of mission time and provide a reference for activities prescribed in the astronaut's flight plans.

The clock in the lunar excursion module will be used to time the landing and take-off on the moon. This seven-digit clock can display elapsed time up to 1,000 hours.

Both the clocks and the electroluminescent displays are hermetically sealed. They are designed to withstand extremes of shock and vibration over a temperature range from 0°F to 140°F.

In addition to these basic clocks, the Apollo astronauts will also carry a number of Sylvania electroluminescent timers. These are designed to time individual experiments on board the lunar module. These units display minutes and seconds on a 2 x 4 inch electroluminescent panel.

Sylvania's electroluminescent panels are available in a wide range of display patterns. The relative ease with which they can be modified makes them readily adaptable to a wide variety of display applications.

CIRCLE NUMBER 305
How synergism brings you new and better circuit assemblies.

A business-oriented definition of synergism might be: “The total strength of an organization is greater than the sum of its individual strengths.” At Sylvania Electronic Components, this definition is continually being applied to satisfy both industry needs and company objectives. Certainly, our newest addition, the Circuit Assemblies Operation, is a perfect example of this type of synergism at work.

The key consideration in any successful product development, regardless of company goals or objectives, must be user benefit. Put in a different way, if our new products don’t help solve a problem for you, then it’s just a wasted effort for Sylvania.

With our new Circuit Assemblies Operation, however, we feel we’re on safe grounds. Electronic circuitry is becoming increasingly more sophisticated, and bigger performance is being demanded from smaller systems. The result is that package design and density have become crucial considerations to the circuit engineer. The industry need, therefore, is for economically produced circuit assemblies manufactured with high reliability and in high volume. And that’s what our new operation is all about.

In addition to user benefit, however, there are two other criteria that must be met. The new product must have profitability and viability (the ability to grow). Thus, before entering the circuit assembly marketplace, Sylvania went through several stages of product evolution.

First of all, there was an exploration stage which quickly showed that circuit assemblies would allow us to optimize the total spectrum of technologies within Sylvania Electronic Components. This included the capabilities to manufacture not only the basic circuit boards, single, double sided or multilayer, but also integrated circuits, diodes and rectifiers, hybrid thick-film circuits, and even vacuum tubes. These capabilities provide a giant step toward the concept of added value.

Then, a screening stage proved the idea to be pertinent enough to merit further study. Next was a business analysis stage which confirmed that the explosive growth in electronic hardware had established significant trends in the circuit assembly business.

Then development, testing, and commercialization were undertaken. In this case, these stages were easily achieved since a full-scale circuit-board facility was already operating as a feeder plant to Sylvania Electronic Systems. It was simply a matter of taking their products to the customer. And that’s being accomplished by the efforts of the Sylvania Electronic Components sales force.

With circuit assemblies, therefore, the synergistic effect has combined the efforts of a number of strong elements within the Sylvania Electronic Components group to produce a new and better product line for you.

But the synergistic part was the easiest part to achieve—it was already there.

P. K. Packard
Product Marketing Manager, Circuit Assemblies

SPECIFICATION RATINGS:

\[ V_{\text{CEX}} = 700\text{V min} \]
\[ V_{\text{CEO(sus)}} = 400\text{V min} \]
\[ h_{\text{FE}} = 15-60 \text{ @ 3.0A} \]
\[ V_{\text{CE(sat)}} = 0.5\text{V @ 3.0A} \]

Also available in 500 Volt \( V_{\text{CEX}} \) versions, 2N5466 and 2N5468; all other specifications identical.

High voltage, triple-diffused silicon power transistors are now available from Solitron, with \( V_{\text{CEX}} \) up to 700 Volts. Typical applications include horizontal deflection circuits, ignition systems, CRT sweep systems, high voltage switching mode regulators, high voltage pulse amplifiers and high voltage pass series regulators. Priced low, they are available in TO-3 and TO-66 cases.

MAGNETICS

keep weaponry on target!

Unlike the cumbersome, clanking gear train of the Monitor's cannon, today's weapons are controlled by sophisticated and silent means. Artillery shells and bombs are exploded precisely on-target by delayed action fuses. A tape core in an oscillator generates pulses for a timing circuit. A bobbin core counts the pulses and actuates the explosive device at the exact instant selected by pre-setting the fuse. Some of our best tape and bobbin cores are blown to bits this way... but they do their job. Forward-looking manufacturers with airborne problems look to Arnold for high-quality magnetic materials, design, technology, components. Magnetic cores. Powder cores. Laminations. Permanent magnets. You ask. We'll supply. The best in magnetic materials.

Arnold Engineering Company, Main Office: Marengo, Ill.
Branch Offices and Representatives in Principal Cities

Write for your free guide to the only complete line of magnetic materials.

Other Arnold products are up in the air too: bobbin cores and MPP cores in aerospace telemetering • Supermendur in smaller, lighter transformers for jets and aerospace • iron powder cores in radio/TV coils • Alnico and Arnox in loudspeakers for radio/TV and communications • Alnico for microwave equipment.
The First Authoritative Single-Volume I/C Reference

...THE INTEGRATED CIRCUIT DATA BOOK

Here is the industry's most complete data guide and the most comprehensive source of general I/C information.

Nearly 1,000 fact-packed pages contain detailed specifications for all Motorola linear and digital integrated circuits, plus:

- INTERCHANGEABILITY CROSS-REFERENCE
- DIGITAL AND LINEAR APPLICATION SELECTION GUIDES
- SELECTED KEY APPLICATION NOTES
- SUPPLEMENTS - UPDATING SERVICE
- SUBSCRIPTION RESERVATION
- ALPHA-NUMERIC CIRCUIT IDENTIFICATION INDEX

Individual sections of the book treat each of the Motorola I/C families: MECL, MHTL, MTTL, MDTL, mWMRTL and MRTL, MOS, Complex Arrays, and each of the linear types. No single I/C information source offers so much toward the intelligent selection of the right device for the specific job . . . yet the price is only $3.95 per copy.

Integrated Circuit Data Book Coupon

Laser faster than radar, tracking Mach 4.5 sled

You're tracking a rocket sled a thousand feet away. It's whizzing along at a track at Mach 4.5—about 3000 miles an hour. You're interested in calculating the range to target at any given instant. How do you do it?

Sandia Corp. of Albuquerque, N. M., is faced with this problem. For its solution Sandia engineers are using a laser tracking system delivered by the Applied Research Laboratory of Sylvania Electronic Systems, Waltham, Mass. Although the tracker was developed for rocket sleds, W. D. Wright, a Sylvania development engineer, suggests that the system may also be used for tracking aircraft and targets that move in three coordinates because of the high sampling rate (1000 a second) used.

Brian P. Fitzgerald, who headed the project for Sylvania, claims that the angular tracking resolution of the system is 25 microradians. This resolution, he says, is orders of magnitude finer than a microwave radar.

The tracker (see figure) follows a cooperative target, and is insensitive to any input but the reflection of its own laser beam off glass retroprisms that are fastened to the sled. A 50-watt helium-neon cw laser is used instead of a more powerful argon ion laser because it lessens the radiation hazard. Wright asserts that a range of "10 miles for tracking an aircraft is not unreasonable even with a helium-neon laser."

The laser output is modulated by the application of two sine waves to a Pockel cell. This electro-optic modulation permits the phase of the laser returns to be compared with the transmitted signal. Ambiguity is resolved by the use of two tones at the same time: One, at 50 kHz, corresponds to 10,000 feet, and the other, 3.2 MHz, to 153 feet. The phase data is digitized and stored on magnetic tape.

The retroprism on the rocket sled returns the laser beam to the gimbal mirror, which directs it along the receiving path. The beam is divided, and the reflected portion is collected by a 5-inch lens, collimated, passed through an interference filter and focused on the face of the image dissector.

Shaft-angle encoders on the servo-driven tracking mount convert the azimuth and elevation angles into data for storage on tape. Azimuth, elevation and range are eventually fed to a general-purpose computer.

Laser system can track aircraft and other targets moving in three coordinates. Its angular tracking resolution is 25 microradians.
Our airborne switches and relays are finding a home in military systems down below.

Specifying Cutler-Hammer airborne switches and power relays is getting to be a habit with more and more designers. They're putting our equipment to work in computers, radar, shipboard electronics, tanks, trucks, power and fire-control equipment.

Good idea. After all, they're using the same components that have proved themselves for nearly 40 years—under the extreme conditions of flight.

No wonder. Cutler-Hammer switches and power relays are designed by pros. People with a world of experience in designing these components to perform normally under some mighty abnormal conditions. They're rigorously inspected at every stage of the manufacturing process, and subjected to unbending quality control standards.

Specify Cutler-Hammer equipment on your next project—whether ground, marine or airborne. Call your local Stocking Distributor or write for new catalogs LL-291-W217 and LL-292-W217.

The natives are friendly.

Some of our relays and switches for ground, sea and airborne installations around the world:

- Miniature and standard-size, positive-action toggle switches built to the requirements of MIL-S-8834, Shallcross rotary switches (to MIL-S-3786), Hermetically sealed power relays and 175-amp generator contactor (to MIL-R-6106).

BOURNS, INC., TRIMPOT PRODUCTS DIVISION • 1200 COLUMBIA AVE., RIVERSIDE, CALIF. 92507
Optimism plus persistence pays off

Just over 14 months ago, Honeywell's Aerospace Div. proposed development of a new satellite called Orbital Scanner, a vehicle designed to perform a comprehensive mapping of the Earth's infrared horizon (see ED 20, Sept. 27, 1967, p. 29). At that time, prospects for funding a new, unmanned, scientific satellite effort appeared dim, because of the overtightening NASA budget. Yet only last month NASA awarded Honeywell a $1-million design-study contract to refine concepts for satellite pointing systems and infrared instrumentation.

There is no question that the project is directly related to the original proposal. Honeywell Aero. Div. general manager E. H. Olson stated that: "This development will be necessary in order to conduct future space missions, such as orbital scanner flights for mapping a new infrared horizon in the Earth atmosphere and earth resources in the 1970s."

Control Data Corp. and Lockheed Missiles and Space Company will work on the 11-month program. CDC is well along in development of star telescopes that will provide vehicle attitude determination. Designed as dual star mappers and a sun sensor, the optical units are intended to assure a 10-arc-second pointing accuracy with respect to the Earth's surface. Lockheed has been developing the IR radiometer employing cadmium-doped germanium detectors that encompass a 0.01° field of view and operate in the 15-micron range. The detectors will be neon cooled.

In July 1967, Honeywell completed a 15-month over-all program study leading to the present program for NASA's Langley Research Center. The current Langley effort could lead to a satellite program in the early 1970s. The original Honeywell proposal called for a 725-lb spin-stabilized spacecraft to be placed in a circular, polar orbit at a 270 nautical mile altitude. The program cost was then estimated at $10 million. In the present contract, CDC will get about $150,000 and Lockheed some $300,000.

RTCA releases new test "bible"

A must for those involved in aircraft avionics systems, the revised "Environmental Conditions and Test Procedures for Airborne/Electrical Equipment and Instruments" is now available. Prepared by over 150 members of the Radio Technical Commission for Aeronautics and three years in the preparation, RTCA Document #DO-138 updates current test data and allows for anticipated needs. It attempts to resolve past conflicts that existed between the subsonic environmental conditions and test procedures set forth in a previous and similar RTCA document (DO-108), and publications of other U.S. organizations. For the future, the report takes into consideration the environmental problems of solar radiation, ultraviolet radiation and acoustic noise effects, as these affect avionic systems. (Copies may be obtained at a cost of $4.00 each through the RTCA Secretariat, Suite 302, 2000 K Street, N. W., Washington, D.C., 20006.)

Air-ground radio-telephone R&D approved

Experimental civil aircraft-to-ground radiotelephone service has been extended by the FCC. Reversing its earlier memorandum that had put a time limit on such development—which, in fact, would have killed such a program—the FCC has approved a split
of authorized channels down to 25-kHz spacing, thus providing 12 channels in the range of the 454- and 459-MHz bands. Two companies, AT&T's Bell System and Litton's Skyphone Div. are currently involved.

Bell has 12 ground stations that are currently equipped to work with the Litton Skyphone flight equipment which links any aircraft into the conventional telephone system. The present experimental system provides only a single channel capability through any one ground station. But Bell believes it will, in time, provide full U. S. coverage on the multichannel basis.

The Skyphone equipment, including power supply, weighs about 30 lb and requires a maximum of 300 watts for an 18-watt transmitter output. Present cost for the flight system is under $4000.

Depending largely on future FCC approval, AT&T Vice President C. L. Elmendorf predicts a need for up to 300 radiotelephone channels in the near future, to satisfy corporate and business aircraft. He proposes that such an operational system might better perform in the 900-MHz band.

Army considers new guided rocket

Early last month the Army invited over 60 aerospace firms to attend a pre-solicitation conference at the Missile Command Headquarters, Redstone Arsenal, Alabama. The classified program centered its discussion on a new "Multiple Artillery Rocket System."

The Army is seeking a mobile launcher that will also be capable of carrying some six to eight of the limited-range Mars rockets for use in area-saturation. Informants here believe the new rocket will be similar in size to the Little John battlefield support missile. Unlike Little John, however, Mars will be guided by some form of stabilization and control system. Odds are, informants say, that a fluidic guidance and control system will be used.

Considerable testing of such a system, using a Little John as the experimental vehicle, has been performed at Redstone where fluidic subsystems developed by Honeywell, General Precision, Martin-Orlando and Corning Glass were employed. The approach taken was to provide only yaw and pitch stabilization with the airframe fins limiting roll. Also, tests that appeared to employ a similarly modified rocket were fired from a multiple launcher at Fort Sill, Okla. last year.

Industry bids for conceptual design-study contracts are expected to be submitted by the end of this year. It is doubted that this program will move to the contract definition stage before the end of 1969.

Whatever the final design, it is certain the Army will hold out for a weapon that is simple, rugged, reliable and more accurate than existing tactical weapons that are limited to a 10-to-15 mile range. Also, the Army is seeking a cost of less than $10,000 in production quantities. Unless these basics are achieved in the conceptual design, informants here doubt that the program will obtain developmental-contract approval from the Secretary of Defense.

Explorer 38 antennas extended fully

The Radio Astronomy Explorer, RAE-1 or Explorer 38, is now operating in space with its massive X-shaped antennas fully extended (1500 feet from tip to tip). When first launched by NASA on July 4, the antennas were only deployed to a length of 455 feet each (910 feet over-all).

Although Explorer 38's mission was to map natural radio sources within our solar system and throughout the Milky Way on a round-the-clock basis, it was feared at first that full extension of the antennas might create an unstable condition that could degrade radio measurements. The partial extension was deemed sufficient to provide all the data desired despite the poorer resolution that would thus be obtained.
Every 260® VOM has Safe/Guard® meter movement protection built-in. Safe/Guard® ends forever the problem of bent pointers and burned-out movements. Also eliminates inaccurate readings caused by the hidden damage of overheating. Safe/Guard® gives positive protection from overloads of over 200,000 Per Cent! Yet, in no way affects the precise calibration of the Simpson 50-microampere movement.

Safe/Guard® is just one of the "extra value" features built into the 260®. Others include: superior linearity and dial calibration; replaceable 1-ampere input fuse; shock-proof, virtually friction-free movement; and the exclusive Adjust-A-Vue® handle which folds down to use as a convenient stand. Solid reasons why the 260® is the world's largest selling volt-ohm-milliammeter.

260-5 with built-in meter protection ....................... $62.00
260-5M (mirror scale) with built-in meter protection ....... $64.00

For virtually 100% protection of the entire instrument . . . be sure to see the GOOF PROOF 260-5P. Button pops out to indicate overloads. Just push to re-set. Write for Bulletin 2078 which lists the entire family of 260® VOMs.

*Model 260-5P has both meter and circuit protection except on the 1000V and 5000V DC and AC ranges, and the 10-amp DC range. Price $94.00

Everyone talks corrected reliability,
here's the way it looks.

Switches under glass.

The heart of every AE correed is a reed switch consisting of two overlapping blades. For protection, we seal them inside a glass capsule. But only after we pull out all the dirty air and pump in a special, pure atmosphere. That way there's no chance of contact contamination or oxidation. Ever.

Notice our terminals are one piece. A special machine delicately forms them to precision tolerances. It's a lot of work, but one-piece terminals have distinct advantages over the two- and three-piece kind.

For one thing, there's no extra joint so you're always assured of a positive contact. Also, one piece terminals are more reliable when the correed is used to switch low-level analog signals. That's because thermal EMF is reduced to practically zero.

A different kind of bobbin.

Since we go through so much trouble with our correed capsules, we designed a special bobbin to protect them.

It's molded of glass-filled nylon. (You know how plastic chips and cracks.) Moisture and humidity have no effect on this stubborn material. No effect means no malfunctions for you to worry about. No current leakage, either.

Running the full length of the bobbin are a series of slots. They pamper the capsules and keep them from getting damaged or jarred.

And to help you remember which terminal is which, we mold the terminal numbers into the end of the bobbin. You can read them at a glance.

Little things mean a lot.

Reliability means that we pay attention to the little things. Like the tiny pressure rods we use in every miniature correed. They're placed at each end of the bobbin, across the one-piece terminals. What they do is prevent stresses from being transmitted from the terminals to the reed blades. This keeps the contact gap right on the button. All the time.

The contacts are normally open. To provide them normally closed, we employ another little device—a tiny magnet. It's permanently tucked into a slot next to the reedcapsule. The magnetic action keeps the contacts normally closed.

Coiled by computer.

Once all the parts are secure in the bobbin, we cover them with protective insulation. Around this, we wind the coil. You can be sure the coil winding is correct. It was all figured out for us by computer.

Our next step is to protect the coil. We do that with more protective insulation.

A coat of iron.

On top of the insulation goes a layer of annealed iron. It acts as a magnetic shield and minimizes interaction between coils. Also, it improves the sensitivity of the entire unit. A coat of iron is standard on all AE correeds.

Finally comes super wrap.

To wrap it all up, we use some very special stuff. A layer of mylar laminated material.

It's so tough we guarantee it to withstand all cleaning solvents known to man.

It's attention to detail that helps us keep our miniature relays miniature. Now we're just waiting to show you how perfectly it measures up to your specifications. Automatic Electric Company, Northlake, Illinois 60164.
Letters

An idea for improving an Idea for Design

Sir:

In the Ideas for Design article "Long-Period One Shot Uses One UJT and Two SCRs" (ED 9, April 25, 1968, p. 88), I have an improvement for the free-running circuit.

After building the circuit, I found that if the time delays, as set by R1 and R6, are very close, it is possible for both SCRs to fire at about the same time, latch and hold both sides on continuously. To correct this fault, and also to introduce a means of controlling which side fires first, I have added a capacitor, as shown in the accompanying drawing. This capacitor is placed in either position A or B, depending upon which side is desired to conduct first. When power is initially applied, a pulse appears at the gate to which the added capacitor is connected, causing that SCR to fire immediately and insuring proper operation thereafter. This capacitor is 0.5 µF, the same as C2, the commutating capacitor.

In addition, in Fig. 1b in the original article, R1 is connected to the wrong point. It should tie to the bottom of R3 and not R4, as shown.

I also found that economy semiconductors such as those shown on my drawing, can be used in place of those used in the original design, if cost reduction is desired.

Harold J. Zuckerman
Electro Miniatures Corp.
South Hackensack, N.J.

A Word from the FAA

Sir:

With reference to "Warning System Features Equipment Compatibility" (ED 17, News Scope, Aug. 15, 1968): The article states the frequencies for the "cooperative time-frequency system" under development by the Air Transport Association (ATA) as being between 1575 and 1590 MHz. The reality is that the problems of frequency spectrum congestion are very much a fact of life in the 1540-1660 MHz band; consequently, the final determination regarding the allocation of frequencies for the ATA system, and for the other systems under development in this band, is yet to be made. In the interim, the collision-avoidance system development is being continued on frequencies between 1600 and 1615 MHz.

I hope that this will clarify the matter for you and your readers.

William B. Hawthorne
Chief, Frequency Management Division, RD-500
Allen-Bradley hot-molded resistors are the first resistors to meet the requirements at the S level of the new MIL-R-39008A specification, which covers the general requirements for established reliability for Insulated Fixed Carbon Composition Resistors. And Allen-Bradley provides this "peak" performance in all three ratings—the 1 watt, 1/2 watt, and 1/4 watt—and over the complete resistance range from 2.7 ohms to 22 megohms! This conclusively demonstrates the superiority of Allen-Bradley's exclusive hot-molding technique. Completely automatic machines developed, built, and used only by Allen-Bradley produce such uniformity from resistor to resistor—billion after billion—that long-term performance can be accurately predicted. And Allen-Bradley hot-molded resistors have no known incident of catastrophic failure. For complete specifications on this quality line of resistors that afford tops in performance, please write to Henry G. Rosenkranz and request Technical Bulletin 5000.

MINIATURE VARIABLE CERAMIC DISC CAPACITORS

The Stangard* / DV Series, miniature variable ceramic disc capacitors, represent an optimum balance of high quality and low cost for commercial and industrial applications.

Nine wide ΔC ranges, each available in 4 versatile mounting configurations, offer high Q and excellent stability in applications such as TV, AM, FM receivers, test equipment, communications equipment, low power transmitters, filters, delay lines and other devices requiring adjustable capacitors. These 3/4" diameter Ceramic Disc Stangard capacitors meet or exceed the applicable requirements of MIL-C-81A.

Write for catalog STD-DV-67-A.

Additional unique features are —

- Rugged construction for exceptionally high resistance to shock and vibration.
- Low loss, low inductance materials for high frequency use.
- Markings permit user to know if capacity is increasing or decreasing with turn of adjustment screw.
- Available in a broad range of temperature coefficients.
- Small physical sizes and low weights for today's space age requirements.
- Designed for either point to point wiring or printed circuit board application.

Accuracy is our policy

The following changes should be made in Les Besser's article, "Combine S Parameters With Time Sharing" (ED 16, Aug. 1, 1968, pp 62-68):

Page 62, Col. 2, last line:
Change (h, y, z and s) to (x, y, z and s).

Page 63 Box:
In Eq. 2, change s12 to s21.
In Eq. 5, change $s_{21}^2$ to $|s_{21}|^2$.
In Eq. 6, change $10\log_{10}(s_{21}^2)$ to $10\log_{10}(|s_{21}|^2)$.

Page 65, Col. 1, three lines below the T-matrix:
Change $s_{22}$ to $s_{21}$.

Page 65, Col. 1, bottom:
The 4x4 matrix, used to represent the real and imaginary parts of a complex $2 \times 2$ matrix, is:

\[
\begin{bmatrix}
  r_{11} & x_{11} & r_{12} & x_{12} \\
  -x_{11} & r_{11} & -x_{12} & r_{12} \\
  r_{21} & x_{21} & r_{22} & x_{22} \\
  -x_{21} & r_{21} & -x_{22} & r_{22}
\end{bmatrix}
\]

where the elements are all real.

This represents the complex $2 \times 2$ matrix:

\[
\begin{bmatrix}
  Z_{11} & Z_{12} \\
  Z_{21} & Z_{22}
\end{bmatrix}
\]

where the Zs are of the form defined in the equation eight lines from the bottom.

Page 66, Col. 2, second line:
Change $Z_{72}$ to $Z_{72}$.

Same column, second line of caption 10:
Change $X_0$ to $X_0$.

Page 67, Col. 1, Step 13:
The transistor base (bottom circuit) should be connected as in Step 14.

Page 68, Col. 1, first line:
Change $s_{11}$ to $S_{11}$.

Same column, third paragraph, line 3:
Change 12-dB to 1.2 dB.

Same column, six lines from the bottom: Instead of requiring that the numerator of the "above expression" be greater than zero, the quantity

\[1 + |s_{11}|^2 - |s_{22}|^2 - |s_{11}s_{22} - s_{12}s_{21}|^2\]

should be greater than zero.

HP application note 95 contains a corrected version of this article and additional information. For your copy, circle No. 380.

INFORMATION RETRIEVAL NUMBER 28
Allen-Bradley cuts space requirements with new sealed type Z cermet trimmers

this latest addition to the Allen-Bradley line of cermet trimmers...the type Z...affords high performance in an especially compact package

The cermet material—an exclusive formulation developed by Allen-Bradley—provides superior load life, operating life, and electrical performance. For example, the full load operation (1/2 watt) for 1000 hours at 70°C produces less than 3% total resistance change. And the temperature coefficient is less than ±250 PPM/°C for all resistance values and throughout the complete temperature range (−55°C to +125°C).

The Type Z is ruggedly constructed to withstand shock and vibration. The unique rotor design ensures smooth adjustment and complete stability under severe environments. The leads are permanently anchored and bonded. The connection exceeds the lead strength—opens cannot occur. Leads are weldable.

The enclosure is SEALED. It is both dust-tight as well as watertight, and can be potted. Mounting pads prevent moisture migration and also post-solder washout. For full specifications on this new spacesaving cermet trimmer, please write Henry G. Rosenkranz, Allen-Bradley Co., 1344 S. Second St., Milwaukee, Wis. 53204. In Canada: Allen-Bradley Canada Ltd. Export Office: 630 Third Ave., New York, N.Y., U.S.A. 10017.

SPECIFICATIONS SUMMARY
Adjustment: Horizontal or vertical.
Temperature Range: −55°C to +125°C.
Resistances: 50 ohms through 1 megohm.
Tolerances: ±20% standard, ±10% available.
Resolution: Essentially infinite.
Rotational Life: Less than 2% total resistance change after 200 cycles.
Rotation: 300° single turn.
End Resistance: Less than 3 ohms.
MIC: the singular and the thick-and-thin

Microwave integrated circuits (MIC) are now in the mainstream of microwave system design. The controlled geometry and reduced parasitics offered by this technology promise to reduce costs and improve reliability. But problems remain. Development work on one of these—circuit fabrication—is underway in the labs of virtually every company in the business.

To get the lowdown, Mike Riezenman, ELECTRONIC DESIGN'S Microwave Editor, visited old friends and made some new ones—all of whom are variously involved in researching three main fabrication technologies: thick film, thin film and monolithic.

In other interviews, Mike learned about different methods for making MICs. If you can't make it to Boston for the NEREM session on the subject, turn to page 25.

ED's Mike Riezenman (left) listens as Charles Greenwald (center), an ITT research manager, details features of a screen-printed thick-film MIC, and Ray Barcklow, ITT tech staff member, holds down right field.

From Frim-to-Miller—right down the line

ED authors often share more than a by-line. Authors Albert H. Frim and Melvin M. Miller, who shared the same institute of learning (Northeastern Univ.), are still "sharing" another Massachusetts "institution"—RCA's Defense Electronics Products at Burlington. Both work on computers and controllers for automatic test equipment: Al Frim does the logic design and Mel Miller develops programing aids for Al's designs. And, no surprise, both have been with RCA for the same time. For another example of what they have in common, turn to pp. 75-76.
Portables with Performance

The Tektronix Type 453

Dual-trace, DC-to-50 MHz bandwidth with sweep delay in a compact 30-pound instrument. Rugged environmental capabilities are combined with performance features normally found only in multiple plug-in instruments. Vertical amplifiers provide 7-ns risetime, DC-to-50 MHz bandwidth, from 20 mV/div to 10 V/div deflection factor. At 5 mV/div deflection factor, risetime is 8.75 ns and bandwidth is DC to 40 MHz. Cascading Channel 1 and Channel 2 provides 1 mV/div deflection factor, DC-to-25 MHz bandwidth. The included Type P6010 miniature 10X probes preserve system bandwidth and risetime performance right to the probe tip. Front panel switching logic permits making 5 mV/div X-Y measurements. Jitter, time coincidence, pulse width and other measurements are easily made utilizing the calibrated sweep delay. Sweep rates are 5 s/div to 0.1 µs/div, extending to 10 ns/div with the X10 magnifier. Solid-state design, with FET vertical inputs, provides low drift and fast stabilization time. AC powered.

Type 453 Oscilloscope $1950

The Tektronix Type 454

DC-to-150 MHz bandwidth, 2.4-ns risetime! This oscilloscope is currently the fastest real-time, general-purpose instrument available. Dual-trace amplifiers provide 150-MHz bandwidth at 20 mV/div deflection factor. At 5 mV/div, risetime and bandwidth are 5.9 ns and 60 MHz respectively. Single-trace displays at 1 mV/div deflection factor permit viewing low level signals. The supplied P6047 10X probes preserve the 150-MHz bandwidth right to the tip of the probe. Sweep rates are 5 s/div to 50 ns/div, extending to 5 ns/div with the X10 magnifier. Calibrated sweep delay permits expanding specific portions of your waveform display for examination in detail. A photographic writing speed of 3200 div/µs (>2500 cm/µs) is provided by the Type 454 Oscilloscope, C-31 Camera, and 10,000 ASA film, without employing film-fogging techniques! X-Y displays, with calibrated deflection factors to 5 mV/div, are possible with the flick of two front panel switches. The Type 454 is mechanically designed to withstand environmental extremes and rough handling. AC powered.

Type 454 Oscilloscope $2600

U.S. Sales Prices FOB Beaverton, Oregon
Making the Measurement... with Tektronix Type 453 and Type 454 Portable Oscilloscopes

Portability

The Type 453 and Type 454 Oscilloscopes are designed to be easily transported. With the adjustable handle locked in the "carry" position, these instruments present a vertical form factor which enables them to be carried at the side using only one hand. The handle rotates to other fixed positions, providing a convenient tilt-stand for bench applications. A front cover prevents accidental damage to the operating controls and seals out dust and moisture while in transit. The cover also provides convenient storage for standard accessories. These compact high-performance instruments are lightweight—the Type 453 weighs 30 pounds and the Type 454 weighs 31 ¼ pounds, including panel cover and standard accessories. Both instruments are designed to withstand environmental extremes and rough handling. Specifications are valid over an operating temperature range of -15°C to +55°C.

The Type 200-1 Scope-Mobile® Cart is specifically designed for the Type 453 and Type 454 Portable Oscilloscopes. This cart occupies less than 18 inches of aisle space and provides storage at the base for accessories or associated instruments.

Extra Performance

Dual-trace vertical amplifiers, calibrated delaying sweep, full-bandwidth triggering, and probe-tip performance are standard features offered by both the Type 453 and Type 454 Portable Oscilloscopes. To enhance these performance features and provide additional measurement value, a complete line of compatible optional accessories are available.

The new P6042 DC Current Probe permits measuring current flow with bandwidth from DC to 50 MHz and deflection factors to 1 mA/div.

Repetitive or single-event waveform phenomena may be photographically recorded using the Type C-30A or C-31 Trace-Recording Camera. A minimum photographic writing speed of 3200 div/µs is provided by the Type 454 Oscilloscope with P11 phosphor, C-31R Camera and 10,000 ASA film—without employing film-fogging techniques!

Type 453 Portable Oscilloscope $1950
Type 454 Portable Oscilloscope $2600
Type C-31 Camera $550
P6042 Current Probe $600
P6046 Differential Probe and Amplifier $690
Type 200-1 Scope-Mobile® Cart $75

Your Tektronix Field Engineer will demonstrate these products on your premises at your convenience. Please call him, or write Tektronix, Inc., Box 500, Beaverton, Oregon 97005.

EDITORIAL

Are all designers business boobs?
We, for one, don’t think so.

We have noticed lately a subtle and disturbing trend in management-oriented literature—sometimes expressed, sometimes implied—to the effect that design engineers know little or nothing about business.

Whether insinuated or stated, the message is clear: designers are an amorphous mass of inward-looking individuals who are more interested in design excellence than in the question, “Will it sell?”

The innocent reader is left with the impression that if left to their own devices, all designers would overdesign their company right out of business.

Of course, some of this does exist. But it is no more prevalent, and probably less so, than those cases where management or sales personnel know little and care less about technical matters.

From our experience, the majority of designers do care whether their components, devices or equipments sell profitably. They do look beyond their breadboards and consider production, packaging and field maintenance problems. And they most certainly do consider design alternatives in terms of cost.

But to expect these same designers to have the business acumen of a comptroller, the marketing insights of a sales manager, and the dollars-and-cents grasp of a cost accountant is foolish.

And to deprecate him when he doesn’t is absurd.

We are not implying here that everything is rosy, or that the average engineering department is staffed with people having the business-technical expertise of a Bill Hewlett, a Dave Packard or a Varian brother.

But by the same token—to borrow an analogy from the automotive field—it would have been grossly unfair to blame Ford’s experience with the Edsel on over-engineering.

Of course improvements are needed. All designers should make every attempt to keep abreast of all of their company’s business, sales and production elements that affect them, and on which they in turn can have some good effect.

But this is a two-way street, and the other departments must reciprocate. Otherwise, their glass partitions may someday come under fire, from rocks thrown by an aroused design community.

FRANK EGAN
HSI 3rd Generation Timers
MADE POSSIBLE BY HSI'S MINIATURIZED COMPONENTS:

These new type timers are smaller, lighter in weight and more versatile than other units heretofore available — **without sacrifice in performance or increased cost.**

After years of development, timers like these finally became possible by using HSI's **BIG INCH™** motors. No other timing motor has ever been built that is so small yet so precise . . . so powerful . . . so efficient and so low in cost.

HSI's 3rd Generation Timers, which open up a wide new range of applications, will initially be custom-engineered for specific OEM applications. Designers may obtain basic data by writing or calling Mr. G. O. Hoffmann at HSI, Inc. 1500 Meriden Rd., Waterbury, Conn., Tel. (203) 756-7441.

Design digital comparators logically. Use off-the-shelf ICs and limit your effort to logical design.

Part 1 of a two-part article

Digital comparators are being built to an increasing extent with off-the-shelf integrated circuits. This eliminates detailed circuit design, and reduces the design task to one of implementing the logic of a particular comparator function.

Further simplification in comparator design is possible if the designer has at his fingertips logic design information for commonly used comparator types. Such information is given here in Figs. 6 through 9. Additional comparator types will be covered in the second part of the article.

Included for each comparator are a description of operation, logic diagram, truth table, Karnaugh map and typical timing waveforms. The actual ICs used in the descriptions are Fairchild Semiconductor Type 930 DTµ,L (diode-transistor micrologic) gate packages. The basic principles are easily applied to other types of ICs.

The following background material applies to all of the specific comparator types described.

Basic comparator is an identity gate

The basic digital comparator is generally an identity gate, which compares the contents of two or more stages or registers and provides an output only when all of its corresponding inputs are equal. For example, as shown in Fig. 1, an output \( F \) will be obtained only when the contents of the \( A \) Register are equal to the contents of the \( B \) Register. No output \( F \) will be obtained if any one of the stages, \( A_i \), is not equal to its corresponding stage, \( B_i \). These conditions are illustrated by the truth table and Karnaugh map for each stage, also shown in Fig. 1, where “1” is a logical HIGH and a “0” is a logical LOW.

For an \( n \)-stage identity comparator, the Boolean equation can thus be written as:

\[
F = (A_1 B_1 + \bar{A}_1 \bar{B}_1) (A_2 B_2 + \bar{A}_2 \bar{B}_2) \ldots \ldots (A_n B_n + \bar{A}_n \bar{B}_n) \tag{1}
\]

which states that the output \( F \) will be HIGH when \( A_i \) and \( B_i \) are both HIGH or both LOW, and when \( A_i \) and \( B_i \) are both HIGH or both LOW, and so forth.

Using inverters and passive AND and OR gates, Eq. 1 could be implemented as shown in Fig. 2. Symbolically, a dot represents an AND gate, a plus sign represents an OR gate, and an arrowhead represents an inverter for obtaining the complement of the input variable.

In addition to the identity comparator, other types of comparators find frequent usage in digital systems. These include:

- \( A \) greater than or less than \( B \).
- \( A \) equal to or greater than \( B \).
- \( A \) equal to or less than \( B \).

There are also comparators which perform such functions as voting or limit determination. Typical of these circuits are the two or more out of three; the two out of four; the greater than four; the less than five, and so forth.

IC characteristics must be considered

When designing with off-the-shelf ICs, in this case Fairchild DTµ,L units, the inverting action of the circuit itself must be taken into consideration. This, in effect, influences the manner in which the Boolean equations are implemented. To illustrate the point, consider a typical DTµ,L 930 gate, shown in Fig. 3. It can be represented schematically as a 4-input diode network and a pair of npn transistors connected in cascade, with two such gates contained on a single chip. The input network is expandable to 8 diodes by the addition of a diode cluster, such as DTµ,L 933.

Circuit operation of the gate itself is as follows: When inputs \( A, B, C \) and \( D \) are all HIGH (+5 V dc), diodes \( CR1 \) through \( CR4 \) are back biased, so that the base and collector of \( Q1 \) are HIGH. \( Q1 \) will then conduct. The resulting voltage drop across \( R1 \) will cause \( Q2 \) to conduct and saturate, so that output \( F \) is LOW (ground potential). If any input \( A, B, C \) or \( D \) goes LOW, its associated diode will be forward biased, placing the base of \( Q1 \) at ground. This condition causes \( Q1 \) to cut off, thereby cutting off \( Q2 \), so that out-
1. The basic digital comparator compares the contents of two registers and produces an output only when the contents of each are exactly equal.

Input $F$ goes HIGH ($+V_{cc}$). In effect, the output is LOW when all inputs are HIGH, and the output is HIGH when one or more inputs are LOW.

At 25°C, the noise immunity of the gate is approximately $+1$ V dc and, as the temperature increases, the noise immunity decreases.

The internal logic diagram of a Type 930 gate package, with lead numbering, is shown in Fig. 4. As a rule, pin 7 is connected to ground and pin 14 is connected to a $+5$-V dc source ($V_{cc}$). If an input line is unconnected, it will act the same way as if a $+5$-V dc level were present.

In terms of logic, the DTµL 930 can be used as a positive NAND or negative NOR, depending solely on the way in which the input and output levels are interpreted. When used as a NAND gate, the circuit provides a LOW output only when all the inputs are HIGH. If one or more inputs are LOW, then the output is HIGH. These conditions can be expressed by Boolean equations:

$$F = ABCD$$

and

$$F = (\overline{A} + \overline{B} + \overline{C} + \overline{D}) + \overline{A} \overline{B} \overline{C} \overline{D}.$$  \hfill (3)

The logic symbol for a 4-input NAND gate is shown in Fig. 5a. A "bubble" on the output line indicates a logical LOW; absence of a "bubble" on an input line indicates a logical HIGH.

When used as a NOR gate, the circuit provides a HIGH output whenever one or more inputs are LOW. If all inputs are HIGH, then and only then is the output LOW. These conditions can also be represented by Boolean equations 2 and 3 above. The logic symbol for a 4-input NOR gate is shown in Fig. 5b. In this case, the "bubble" on an input line indicates a LOW, and absence of a "bubble" on the output line indicates a HIGH.

Use of a DTµL 930 gate as an inverter is illu-
trated in Fig. 5c. The output is LOW when the input is HIGH, and vice versa.

Logical designs are illustrated

Based on the foregoing material, the logical design of a variety of digital comparator types is detailed in Figs. 6 through 9. For convenience, only converters operating on a limited number of bits are illustrated. The designs, however, can be applied to any number of bits or stages, provided loading requirements are met.

When referring to the circuit descriptions given in Figs. 6 through 9, note that inputs and outputs are referred to as Z3-2, Z1-3, Z2-1 and 6. A = B comparator (2-bit)

This identity comparator provides a logical HIGH output when the two inputs, A and B, are both HIGH or both LOW. For example, if A and B are HIGH, Z2-6 will be LOW and Z3-6 will be HIGH. When A and B are LOW, Z2-8 will be LOW and Z3-6 will again be HIGH.

\[ F = AB + \overline{AB} \]

Timing diagram:
This comparator provides a logical HIGH output when every A input is identical (HIGH or LOW) to its corresponding B input. For example, when A₁ and B₁ are HIGH, Z2-6 will be LOW and Z3-6 will be HIGH. To obtain a HIGH output from the comparator, the 9, 10 and 12 inputs to Z8 must all be HIGH. If any of these inputs are LOW, Z9-6 will be LOW, indicating that not all of the A inputs are equal to their corresponding B inputs.

Logic diagram:

Karnaugh map:

\[
F_i = A_i B_i + \bar{A}_i \bar{B}_i
\]

\[
F = (A_1 B_1 + A_1 B_1) (A_2 B_2 + A_2 B_2) (A_3 B_3 + A_3 B_3)
\]

Timing diagram:
This comparator provides two outputs: \( A > B \) and \( A < B \). The "greater than" output, \( F_1 \), is a logical HIGH if the \( A \) input is greater than the \( B \) input. Similarly, the "less than" output, \( F_2 \), is HIGH if the \( A \) input is less than the \( B \) input. When \( A \) and \( B \) are equal, both outputs are LOW. For example, assume that \( A \) is HIGH and \( B \) is LOW. Then \( Z1-6 \) will be HIGH. With inputs 9 and 10 of \( Z1 \) HIGH, \( Z1-8 \) will be LOW and \( Z3-6 \) will be HIGH. Also, pins 9 and 10 of \( Z2 \) will be LOW, making \( Z2-8 \) HIGH and \( Z3-8 \) LOW. This is the condition for \( A > B \).

9. A > B and A < B comparator (8-bit)

This comparator compares two 4-bit numbers, starting at the highest-order bits (A_8 and B_8) and working down to the lowest-order bits (A_1 and B_1). If the numbers are identical, both comparator outputs, F_1 and F_2, are LOW. If one of the numbers is larger than the other, its corresponding output line (F_1 for A > B and F_2 for A < B) will go HIGH.

For example, assume the numbers 1010 and 0110 are being compared, with the leftmost digits in the numbers being A_8 and B_8, respectively. In this case A_8 is HIGH and B_8 is LOW, so that B_8 is HIGH. Output Z1-6 is therefore LOW, inhibiting Z2, Z3 and Z4, and causing Z6-9 to go LOW and Z6-8 to go HIGH. This is the condition for A > B.

If, when comparing two numbers, A_8 and B_8 are equal, Z1-6 and Z1-8 are HIGH, so that Z2-4 and Z2-9 are also HIGH. And if A_4 is LOW and B_4 is HIGH, then A_4 is HIGH, making Z2-10 and Z2-12 HIGH. As a result, Z2-8 and Z6-4 are LOW and Z6-6 is HIGH. This is the condition for A < B.

Logic diagram:

Logic equations:

A > B: F_1 = \overline{G_1} + \overline{G_2} + \overline{G_3} + \overline{G_4}

A < B: F_2 = G_5 + G_6 + G_7 + G_8

where:

\overline{G_1} = A_8 \overline{B_8}
\overline{G_2} = G_5 (A_4 \overline{B_4})
\overline{G_3} = G_6 G_5 (A_2 \overline{B_2})
\overline{G_4} = G_7 G_6 G_5 (A_1 B_1)

\overline{G_5} = A_8 B_8
\overline{G_6} = G_1 (A_4 B_4)
\overline{G_7} = G_2 G_1 (A_2 B_2)
\overline{G_8} = G_3 G_2 G_1 (A_1 B_1)

Silicones can prevent grounding

Silicones can play a vital role in assuring electronic equipment reliability — key to operational readiness. That's because they provide excellent protection against the harsh environments inherent to worldwide operations.

Silicone electronic materials from Dow Corning comprise an entire family of dielectrics: fluids, grease-like compounds, gels, rubbers, adhesives, potting and encapsulating materials, molding compounds and surface coatings.

All provide outstanding dielectric and physical properties:

- Resistance to moisture — sea or fresh water and high humidity
- Temperature stability —60 to 300 C
- Long term heat aging — more than 10,000 hours at 250 C for most materials
- Mildew resistance — nonnutrient to fungi
- Inertness — to oxygen, ozone, many chemicals
- Electrical parameters — good volume resistivity, dissipation factor, dielectric constant, arc resistance and electric strength

Dow Corning silicone electronic materials have already proven themselves in aerospace, aviation and ground support equipment. Many typical uses are cited in our Military Electronic Design Guide such as filling, potting, encapsulating, embedding and other applications.

If you are involved in keeping military electronic gear airborne, write for your copy to Dept. B-8471, Dow Corning Corporation, Midland, Michigan 48640.

DOW CORNING

Shock and vibration are two of the operational environments that take heavy toll of delicate electronic gear. Improved protection is available with a new shock absorbent Dow Corning solventless silicone encapsulating resin which absorbs these forces with very little internal reaction.

Designed for electronic use, a new Dow Corning material is the first noncorrosive one-part silicone adhesive/sealant that cures without emitting by-products that can affect sensitive electronic contacts and circuits. The material cures at room temperature to provide a tough, resilient silicone rubber bond between metals, plastics, painted surfaces, ceramics and silicone coated surfaces.
Do computations at the speed of light.
Use optical data processing for instant Fourier analysis. Fraunhofer diffraction is the key.

To most engineers the word "computer" means electronic digital computer. However, over the past few years, a newer and, for certain important system applications, superior device has come into being—the optical data processor (ODP), or optical (or laser) computer.

Here we will discuss some of the basic operations that can be performed by optical computers. Most of these tasks can also be done with electronic systems, often to greater accuracy. But if large quantities of wideband data are to be operated upon, the electronic techniques are often prohibitively expensive and time-consuming. Here is where the laser computer shines.

The optical computer is faster than a digital computer because it operates on signals that are functions of position, not time. That is to say, the input to an optical data processor is a pattern of light intensity that varies over some area, not a light intensity that varies as a function of time. This has two important consequences:

1. The optical computer is able to directly handle signals that are functions of two independent variables, because it is just as easy to make the density of an optical mask vary over two dimensions as one.
2. Normally time-consuming operations, such as integration, can be performed virtually instantaneously because all of the input data is available simultaneously, the integration being over space, not time.

Thus optical data processing is most appropriate for such lengthy operations as the calculation of complicated Fourier transforms and the processing of side-looking radar signals.

Now, since most signals of interest here are electronic, the first job must be one of signal conversion. A present constraint for some applications is the lack of good converters to go directly from electronic signals to optical signals. Electronic signals must be recorded on photographic film with a cathode ray tube, and the film developed and used to read the data into the computer. The output is frequently an electrical signal generated by a mosaic of photocells. However, if a photographic record is desired, the delays due to film processing will be doubled.

Discovery of ways to overcome this drawback and allow operation in near real-time would offer definite advantages. Toward this objective, much work is in progress in many laboratories on recording materials such as photochromics, thermoplastics and other exotic films that would instantly store image information, yet could be readily erased for reuse. There is every reason to believe that this problem will soon be solved. For many applications, though, the time needed for processing the film is small compared to the time saved by using optical processing.

As an example of the capabilities of the optical data processor consider the problem of restoring the photograph of Fig. 1 (top). The photograph is blurred because of atmospheric turbulence between the camera and the subject. As will be explained later, this blurring represents a loss of the higher spatial frequency components of the picture. To improve the picture, it is necessary to (1) form its spatial Fourier transform, (2) filter it through an appropriate high-pass filter, and (3) take the inverse transform.

These corrective procedures can, of course, be carried out on a digital computer using a Fourier transform program. Appropriate interface equipment must be used to read and digitize the photograph. Additional read-out equipment must then be provided to convert the corrected intensity values (numbers) to a light intensity that can be photographed.

A 35-mm picture with a 50 cycle per millimeter spectrum represents approximately three million bits of information. To transform, filter, and retransform so much information—even using the Cooley-Tukey fast Fourier transform algorithm—would require several hours on a high speed digital computer equipped with a large memory.

With optical data processing equipment, on the other hand, the computation time required is about 10 nanoseconds—the time it takes light to traverse the ODP. Read-in time is zero, and a read-out time of several seconds would be required to record the restored image on high resolution film.

On a cost basis, certainly, the arguments substantially favor the ODP.

To understand the process, we'll have to go back a few steps and begin with the fundamentals:

**Fraunhofer diffraction: the basis of the ODP**

Diffraction is the basic property of light that makes it appear to bend around an object placed in its path. Consider the simple experiment shown in Fig. 2. An aperture consisting of a narrow slit, $S$, is placed in a beam of parallel light. A screen, $O$, is set up behind the slit. It would seem that one should see a single sharp shadow of $S$ at $O$, i.e., the geometric image. However, the pattern of light at $O$ is structured as shown on the right in Fig. 2. The departure of the actual pattern from the simple sharp-edged shadow is due to diffraction.

Further experimentation would reveal that the pattern depends on the size of the slit, the wavelength of the light, and the distance between $S$ and $O$. By using Huygen's principle that each point on the slit can be regarded as a secondary source of light, and integrating over the aperture, the pattern of light on $O$ can be calculated. This operation is the so-called Fresnel-Kirchhoff diffraction integral.

Suppose now that the screen is moved farther and farther back from the slit. In fact, let us take the observation screen back an infinite distance from $S$. The simple way of accomplishing this in the real world is to employ a converging lens. The setup for the experiment is shown in Fig. 3. For historical reasons, this is called Fraunhofer diffraction.

Now, parallel rays of light emanating from $S$ will not have to go to infinity to meet, but will meet at a distance behind the lens equal to the focal length, $f$, of the lens. It is now found that the shape of the diffraction pattern depends solely on the geometry of the input slit; only the scale of the pattern can be altered by changing the wavelength $\lambda$ of the incident light and the focal length of the lens.

Thus, two distinct classes of diffraction pattern can be obtained: the near-field or Fresnel case, and the far-field or Fraunhofer case. For Fraunhofer diffraction, the Fresnel-Kirchhoff integral reduces to:

$$G(u, v) = c \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} g(x, y) e^{i \pi (u x + v y)} \, dx \, dy, \quad (1)$$

where:

- $x$ and $y$ are distance coordinates in the aperture (object) plane and $u$ and $v$ are similar coordinates in the plane of the screen, $O$, or image plane. For both coordinate systems, the origin lies on the optical axis of the system.
- $c$ = a constant.
The optical computer

Light coming from the cw laser (a few milliwatts is enough for most applications) passes through a microscope objective lens and a pinhole, which form a low-pass spatial filter (see text) for expanding and cleaning up the beam, i.e., removing unwanted intensity variations or hot spots.

$L_1$ is a collimating lens that renders the diverging light parallel. Next in the plane $P_1$ is the input film, usually contained in a liquid gate assembly. A fluid whose index of refraction matches that of the film base and/or emulsion is used to eliminate phase noise—the random variation of optical phase across the film caused by variations in film thickness. Lens $L_2$ extracts the Fourier transform of the input film and presents it as a complex amplitude distribution in plane $P_2$, the Fourier transform (F.T.) plane. It is in plane $P_1$ that various spatial filters can be placed to operate on the transformed signal. The lens $L_3$ extracts the inverse Fourier transform and presents the processed image in plane $P_3$. (Theoretically, $L_3$ is not really needed. The inverse transform should form in plane $P_3$, located in accordance with the thin-lens formula (Eq. 7). However, practical considerations involving the characteristics of available lenses make it desirable to use a two-lens system).

Note that plane $P_2$ is located a distance behind $L_2$ equal to the focal length of $L_2$; similarly, $P_3$ is one focal length behind $L_3$. The focal lengths of lenses $L_2$ and $L_3$ are $f_{L_2}$ and $f_{L_3}$ respectively.

Some applications of the optical computer do not require all of the components shown here. Integration, for example, does not require $L_3$. The detector is placed directly in the F.T. plane.

Note, in the photograph, that Author Horner's left hand is touching the filter holder in plane $P_2$. A directional low-pass filter can be seen in the holder.

Most optical-computer-design problems arise in lens selection. However, reasonably good results can be obtained with good-quality lenses intended for photographic use. Several companies make lenses specifically for taking Fourier transforms and optical data processing.

\[ g(x, y) = \text{an arbitrary function describing the amplitude distribution of light at the aperture.} \]

\[ G(u, v) = \text{the amplitude of diffracted light in the focal plane of the lens.} \]

Eq. 1 is related in a simple way to the two-dimensional Fourier transform of the function $g(x, y)$. This transform is a more general statement of Fourier's theorem for periodic functions. The theorem states that for a function $g(x, y)$:

\[ g(x, y) = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} G(v_x, v_y) e^{-2\pi i (v_x x + v_y y)} \, dv_x \, dv_y \]

and

\[ G(v_x, v_y) = (1/2\pi) \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} g(x, y) e^{2\pi i (v_x x + v_y y)} \, dx \, dy \]

Eq. 1 becomes

\[ G(v_x, v_y) = c \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} g(x, y) e^{2\pi i (v_x x + v_y y)} \, dx \, dy \]

Note that the infinite limits of integration can be replaced by some finite aperture size, $A$, since any actual signal will be zero outside some finite region. The entire equation is a two-dimensional transformation in $x, y$ space, with the corresponding variables $v_x$ and $v_y$ in transform space. The variables $v_x$ and $v_y$ are spatial frequencies measured in cycles per unit length. Optical signals that change drastically over short distances (in a plane) are characterized by spectra with large amounts of the higher spatial frequencies. Similarly, signals that change only gradually have low-frequency spectra.

It is clear, then, that the image formed one focal length behind any converging lens is equivalent to the Fourier transform of the input amplitude

\[ v_y = (1/\lambda) u \]

\[ v_y = (1/\lambda) v \]

\[ v_x = (1/\lambda) u \]
pattern if the input object is illuminated with coherent, parallel, monochromatic light—a laser source.

This is illustrated in Fig. 4. Note that the Fourier transform is formed one focal length behind the lens, regardless of the image and object distances ($d_i$ and $d_o$, respectively).

It will be noted that the optical system works as would be predicted by the simple thin lens formula, namely

$$1/f = 1/d_i + 1/d_o$$

The idea of the optical computer (see box) is merely to make use of the Fraunhofer diffraction pattern occurring in the transform plane by placing filters there to operate on the (spatial) spectrum of the input signal. The filtered spectrum is then converted back into the distance-domain by a second lens, which performs the inverse transformation, Eq. 2. (Actually, a lens can only take repeated Fourier transforms of a signal. But the inverse transform can be regarded as a Fourier transform in an inverted coordinate system. Hence, the image in the output plane is inverted.)

An input function can be recorded on a piece of photographic film as a density variation; the amplitude transmission, $t_a$, is a convenient variable. It is the fraction of light passed by the film and varies from 0.0 to 1.0.

One of the simplest mathematical operations to perform optically is the multiplication of two signals. Two pieces of film are placed in series, one behind the other, in the path of a laser beam. The amplitude of light at each point immediately behind the second transparency is proportional to the product of the signal on each transparency. For example, if $t_{a1}$ is a gray transparency that passes 0.5 of the incident light and $t_{a2}$ passes 0.8 of the light, the output will be $0.8 \times 0.5 = 0.4$ or 40% of the incident amplitude.

**Calculus is easy with an optical computer**

Differentiation and integration are easy and virtually instantaneous when performed optically. Consider differentiation. Take the first derivative of Eq. 2 with respect to one of the variables, say $x$.

$$\frac{\partial g(x, y)}{\partial x} = \frac{\partial}{\partial x} \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} G(v_x, v_y) \cdot e^{-i2\pi(v_x x + v_y y)} \, dv_x \, dv_y$$

$$= \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} G(v_x, v_y) \cdot (-i2\pi v_x) e^{-i2\pi(v_x x + v_y y)} \, dv_x \, dv_y$$

$$= k \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} G(v_x, v_y) \cdot v_x \cdot e^{-i2\pi(v_x x + v_y y)} \, dv_x \, dv_y$$

where $k =$ complex constant.

Thus to take the derivative of a function with respect to the $x$-direction, multiply the spectrum, $G(v_x, v_y)$, by a filter proportional to $v_x$, and then take the inverse Fourier transform. Fig. 5 shows a plot of the filter and its physical realization. Negative values of the filter are achieved by shifting the relative phase of the light by $180^\circ$, or one-half the wavelength, $\lambda/2$. This can be done by depositing a layer of clear dielectric on a glass substrate—similar to the process for putting antireflection coatings on lenses and optical plates. Fig. 6 shows the result when a square pulse is differentiated in the $x$-direction.

Consider integration. Inspection of Fourier's
The \((\sin x)/x\) function on the right is the Fourier transform of the narrow slit on the left. Actually, there should be another dimension to the transform, but \(b\) is assumed so large that \(1/b\) is infinitesimal. Note the inverse relationship between the slit and transform widths.

The Fourier transform of the narrow slit of Fig. 7 was used to make this photograph. The absolute value squared—the intensity—is what has actually been recorded.

The fundamental theorem shows that the definite integral of a function is equal to the Fourier transform evaluated at \(v_x = v_y = 0\).

Since the spatial frequency scale is linear (Eqs. 4 and 5), the position of \(v_x = v_y = 0\) is the origin or optical axis of the system. Thus, to instantaneously integrate the two-dimensional function, one merely measures the light level on the optical axis in the Fourier transform plane. After the language of electronics, this point is often called “the dc spot” by workers in the field.

**Spectrum manipulation made simple**

Just as it is frequently instructive to examine the Fourier spectrum of a time-varying electronic signal, so is the optical Fourier spectrum—in terms of the spatial frequencies present—sometimes useful. The optical Fourier spectrum represents the decomposition of a complicated amplitude pattern in terms of optical sine waves.

It is instructive to compute the Fourier transform of a simple function, and compare it with the results obtained using the optical computer. For the function, consider a rectangular slit:

\[
g(x, y) = \begin{cases} 1 & |x| < a, \ |y| < b \\ 0 & \text{otherwise} \end{cases}
\]

According to Eq. 6, the Fourier transform is

\[
G(v_x, v_y) = \int_{-a}^{a} \int_{-b}^{b} g(x, y) \cdot e^{i2\pi(xv_x + yv_y)} \ dx \ dy \quad (9)
\]

We will assume that the slit width, \(2a\), is less than the input aperture width, and that the aperture has a length \(2b\). Eq. 9 becomes:

\[
G(v_x, v_y) = \int_{-a}^{a} \int_{-b}^{b} \cdot e^{i2\pi x v_x} \cdot e^{i2\pi y v_y} \ dx \ dy
\]

This can be put into more useful form by using Euler’s identity:

\[
e^{i\phi} = \cos \phi \pm i \sin \phi.
\]

Equation 10 becomes:

\[
G(v_x, v_y) = \frac{\sin 2\pi v_x a}{\pi v_x} \cdot \frac{\sin 2\pi v_y b}{\pi v_y}
\]

This is a product of two functions of the type \((\sin x)/x\), called the sinc function. Figure 7 shows the computed transform and its relationship to the dimensions of the slit. Note that if the slit broadens in the \(x\)-direction, the transform will narrow.

Since the slit is assumed very long in the \(y\)-direction, the transform, as a function of \(v_y\), is essentially zero except at \(v_y = 0\). Hence only a one-dimensional plot is needed in Fig. 7.

Another property, without an analog in the world of one-dimensional electronics, is that the input signal and its transform are orthogonal. A vertical slit has its transform in the form of a horizontal slit and vice versa.

Fig. 8 is a film recording of the spectrum of a slit. Alternatively, the output data could be recorded by a photocell scanner and strip-chart recorder.

Since both film and photocells respond to energy, the absolute value squared of Eq. 12, or the intensity, \(i\), is what is recorded.

The radial distance from the origin in the transform plane is proportional to the spatial frequency, and the intensity of light at any point is proportional to the intensity of that frequency component in the Fourier transform. Note that both positive and negative frequencies are present.

Having a plane in space where a Fourier transform is displayed allows one to duplicate many of the filtering tricks that electronics can do. For example, a sharp-cutoff, low-pass filter is constructed by simply punching a hole in an opaque card. When inserted in the Fourier transform plane, only spatial frequencies within the clear aperture can get through. This is the basis for the lens-pinhole assembly in the box. Unwanted intensity variations in the laser beam correspond to higher spatial frequencies. A small pinhole (typically 0.001 inch) allows only the very low frequencies or dc to emerge from the assembly and...
be collimated by lens $L_1$. This filter has nearly infinitely steep sides, a feat of optics that is difficult to do electronically. Figure 9 shows several other filter configurations and their electronic equivalents.

Such binary (because they are everywhere either clear or opaque) amplitude filters have been used by geophysicists in removing unwanted and confusing structure in seismic data. Another application (see “Optical computers poised for systems role,” ED 8, April 11, 1968, pp 25-32) is the removal of the lines between individual film strips in a picture mosaic assembled from lunar orbiter probe data.

**Optical correlation saves phase**

For many applications it is necessary to modify the Fourier spectrum of a signal, not only in amplitude but also in phase. In other words, a complex filter is desired. A basic problem in fabricating such a filter is that a photographic emulsion (the usual medium used to record both signal and filter) responds only to intensity.

But the intensity of a complex optical signal,

$$r(x, y) e^{i\phi(x, y)},$$

is

$$i(x, y) = [r(x, y) e^{i\phi(x, y)}] \cdot [r(x, y) e^{i\phi(x, y)}]^*,$$

$$= r(x, y) \cdot r(x, y)$$

where $r$ and $\phi$ are real functions, and $*$ denotes the complex conjugate operation. In other words the phase information, $\phi(x, y)$, has been lost in the recording process.

A. VanderLugt, a research scientist at the Institute of Science and Technology of The University of Michigan, realized that the scheme used to record both phase and amplitude in holography could be applied to optical data processing. To see how this comes about, let us take a carrier function, $e^{i\alpha x}$ and add it to the complex signal we wish to record on film. The intensity of the resulting distribution will be

$$i(x, y) = \text{Re} \left\{ r(x, y) e^{i\phi(x, y)} + e^{i\alpha x} [r(x, y) e^{i\phi(x, y)} + e^{i\alpha x} r(x, y) \cos \alpha x - \phi(x, y) + r(x, y) \cos [\phi(x, y) - \alpha x] \right\}$$

$$= 1 + r^2(x, y) + r^* (x, y) \cos \alpha x$$

Thus the amplitude and phase information have both been converted to an intensity signal to which the photographic film is sensitive. $\alpha$ here is the carrier frequency, and a constant.

VanderLugt incorporated his scheme in an optical computer to determine how alike are two signals. Mathematically this is the process of cross-correlation, defined as

10. The complex conjugate of a function is formed by allowing a reference beam (obtained from an off-axis lens) to interfere with the main beam. Phase data are converted to intensities and, as such, can be recorded on film.

The important feature of Fourier transformation, of course, is its position invariance, i.e., the stationarity of the power spectrum with respect to translations of the imagery. Moment invariants are even better in this respect — they are not only position invariant, but also invariant with respect to changes in size and angular orientation.

The potential of the moment-invariant technique is obvious. For suppose we wanted to look for all the airplanes in an aerial photograph. Airplanes, of course, vary in size, position and orientation, but the basic shape is always the same. Now, moment invariants depend only on the shape of the object. Thus, by examining the moment-invariant spectrum of the

11. X marks the spot where the phrase moment-invariant appears. A filter was made of this phrase and the page of the text was used as an input. The correlation peaks have an X shape because an X shaped mask was put in the beam when the filter was made.
The correlation, $\tau_{12}$, is a pure number, and will change for each different value of $x'$ and $y'$. If the functions $g_1$ and $g_2$ are identical, $\tau_{11}$ is referred to as the auto-correlation.

It can be shown that the auto-correlation function is also equal to the Fourier transform of the power spectrum:

$$
\tau_{12} (x', y')
= \int A g_1 (x + x', y + y') g_2^* (x, y) \, dx \, dy. \quad (15)
$$

The way to extract the correlation is now clear: (1) Form the complex conjugate of the Fourier transform of one function; (2) multiply it by the Fourier transform of the other function; then (3) take the Fourier transform of the product. Optically, the correlation will be a spot of light whose amplitude is proportional to the correlation integral.

Figure 10 shows how to perform step 1. Steps 2 and 3 are performed in the optical computer by putting one of the functions to be correlated in the input plane, and the filter of step 1 in the F. T. plane. It happens that this filtering is identical with the theory of matched filtering when the two signals are the same (autocorrelation). Matched filtering is the technique of maximizing the ratio of peak signal value to mean square noise, when the noise is random and additive.

In this type of optical correlation, it is not necessary to move one signal relative to the other to produce the correlation. The brightest spot of light occurs in the output where the correlation is maximum. It is this unique property of the coherent optical correlator that makes the device useful for rapid automatic pattern recognition.

An example of this is shown in Fig. 11. A filter has been made of the key word, moment-invariant. A page of text is used for the other signal. Everywhere in the text that the key word occurs, a correlation maximum occurs in the output. The correlation peak is in the form of an X for easy identification. This was done by putting a mask, in the shape of an X in the beam while making the filter. A photocell mosaic could be used to automatically count or signal the correlation.

There are many potential applications for rapid automatic pattern recognition. For instance, aerial photographs could be routinely and automatically searched for missile sites or other strategic targets. Mail sorting as well as fingerprint identification could benefit by optical correlation techniques. Conductron Corp. is, in fact, developing a fingerprint correlator with a possible search rate of 10,000/s.

Another area where the optical computer shines is in the modeling of antenna arrays. In designing an array, one must determine its radiation pattern. However, one would like to do this without going to the trouble and expense of actually building the array. Thus, it would be nice to have a model of the array to experiment with, perhaps one that could be conveniently set up on a table top.

One very useful piece of information about an array is its far-field or Fraunhofer diffraction pattern. This, as we have seen, is equivalent to the Fourier transform of the amplitude pattern. By scaling down the wavelength from microwaves to the laser line, a reduction in the size of the antenna of approximately 3 cm / 6328 A = 50,000 is possible.

Figure 12 shows the optical model of an antenna proposed by the Australian Government for scanning the sun. It consists of 96 parabolic antennas. The antennas are equally spaced on a circle one and a half miles in diameter. The size of the circle on the film transparency was 2 millimeters, giving a scale factor of about $8 \times 10^{-7}$:1. A laser of wavelength 6328 A was used. This is a frequency of about $4 \times 10^8$ MHz. When multiplied by the scale factor, this corresponds to 390 MHz.

Figure 13 shows the far-field Fraunhofer diffraction pattern recorded in the Fourier transform plane, $P_2$, of the optical computer. Both normal exposure and long exposure are presented to show the gross pattern and the complicated detail in the side-lobes.

Of course, the same pattern could have been computed on a digital computer, or observed from a satellite at a distance of 2400 miles out in space. But pattern synthesis by optical simulation is far
13. The far-field radiation pattern of the antenna array of Fig. 12 is shown with normal exposure (left) and long exposure (right). The patterns were recorded in the
easier and in this case almost incredibly simple.
Phase information could be incorporated into the antenna structure by using a dielectric coating of the proper thickness to change the phase of each element by the desired amount.

**Enhance images with spatial filtering**

Using an optical computer, one can correct photographs suffering from such things as out-of-focus adjustment, blur caused by camera or object motion during the exposure, and loss of resolution due to atmospheric turbulence during exposure by spatial filtering techniques. All of these defects are characterized by a reduction of the higher spatial frequency spectrum in the picture. Therefore, the restoration requires basically a highpass spatial filter. To understand the technique, one must see the image-forming process as a convolution process. In incoherent light the equation for the image is

\[
i'(x', y') = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} s(x, y; x', y') i(x, y) \, dx \, dy,
\]

where
- \( i' = \) the light intensity in the image,
- \( s = \) the point spread function,
- \( i = \) the intensity of the original scene.

The point-spread function describes the intensity pattern in the image plane when the object is an infinitesimal point source of light. This is analogous to the impulse response function of an electrical network. Ideally, \( s \) would be a gradually vanishing narrow function determined only by the size of the lens—the so-called diffraction limit. In practice, imperfect lens systems and external factors such as image motion and atmospheric turbulence can degrade (widen) the point-spread function. If it is translation-invariant over some region of object-image space (analogous to the time-invariant requirement in electronic filter analysis), Eq. 17 can be simplified to give:

\[
i'(x', y') = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} s(x' - x; y' - y) i(x, y) \, dx \, dy
\]

\[
i'(x', y') = s \cdot i
\]

where
- \( \cdot \) denotes the convolution operator.

The intensity pattern, \( i' \), is used to expose a photographic emulsion. Next, the developed emulsion is placed in the input plane, \( P_1 \), of the computer (see box). If the film exhibits a linear relation between the incident exposing light intensity and the developed amplitude transmission, then the light amplitude, \( a(x', y') \), in the input plane of the computer will be

\[
a(x', y') = Ks \cdot i
\]

In the first transform plane, \( P_2 \), the light amplitude will be the Fourier transform of the input

\[
A(v_x, v_y) = F.T. [s \cdot i].
\]

A theorem that states that the Fourier transform of a convolution integral is equal to the product of the transformed functions, when applied to Eq. 21, gives

\[
A(v_x, v_y) = S(v_x, v_y) \cdot I(v_x, v_y)
\]
The right side is now a product of the spread function transform and the original undistorted scene spectrum. Now the trick is to synthesize a filter to be inserted in the transform plane, $P_2$, whose transmission is

$$1/S(v_x, v_y)$$  \hspace{1cm} (23)

This gives for the light behind the filter:

$$S(v_x, v_y) \cdot I(v_x, v_y) \cdot 1/S(v_x, v_y) = I(v_x, v_y)$$  \hspace{1cm} (24)

In the output plane, $P_3$, the inverse Fourier transform is produced

$$\text{F.T.}^{-1}[I(v_x, v_y)] = i(x', y').$$  \hspace{1cm} (25)

In other words the degraded image, $i'$, has been deconvolved from the point spread function, $s$, in the optical computer to give a reproduction of the original undistorted scene. Information theory predicts that the restored scene will not be perfect because of the noise present in any real system, but considerable enhancement of picture detail can still be accomplished.

Consider a scene blurred by atmospheric turbulence. We produced this in the laboratory by placing a hot plate under the camera lens (out of sight) and making a time exposure of an aerial photograph. The narrow point spread function of the optical system became a wide blur which, to a good approximation, can be represented by the Gaussian function

$$s(r) = e^{-r/r_0^2}$$  \hspace{1cm} (26)

where $r = (x^2 + y^2)^{1/2}$ and $r_0$ is a constant which depends on the amount of turbulence in the atmosphere. To make the inverse filter we take the Fourier transform of $s$ and invert it—Eq. 23. The Gaussian function has the property that its Fourier transform is also a Gaussian function:

$$\text{F.T.}[e^{r/r_0^2}] = ke^{-(\nu/r_0^2)}$$  \hspace{1cm} (27)

where $\nu = (v_x^2 + v_y^2)^{1/2}$.

Hence, the inverse filter is

$$ke^{-(\nu/r_0^2)}$$  \hspace{1cm} (28)

where $k$ is a normalization constant to make the maximum value of Eq. 28 equal to unity at the highest spatial frequency in the input film.

Fig. 1 shows the blurred, unfiltered aerial scene, and also the same scene after spatial filtering. Note the improvement in fine detail, such as the windows.

With the exception of the image-enhancement application, the optical data processing techniques that we have been discussing require only reasonable mechanical tolerances in order to work as described. Any converging lens will produce a Fourier transform, but the transforms produced by high-quality lenses will have less distortion than those produced by cheap lenses.

Precise positioning of filters along the optical axis in the transform plane is not essential for successful operation—errors of a few millimeters are usually acceptable. In fact, when using photographic transparencies as filters, it is necessary to defocus slightly to avoid burning the film with the extremely intense dc spot that exists precisely in the transform plane.

The selection of a laser for an optical computer is simple. A cw laser is needed. Since high power and efficiency are not important and spectral purity is, a gas laser is the obvious choice. Ordinary off-the-shelf gas lasers have very narrow spectra (see "Advances in Lasers," ED 19, Sept. 12, 1968, p. 49) and adequate power for this application.

As the wave of the future in computer technology we can expect to see a marriage of the optical computer with integrated circuit components to yield new speed and compactness. For example, a mosaic of IC photodetector and decision circuits could be used to process the Fourier transform data generated by optical means.

Considering that the whole field of optical data processing is less than a decade old, many advances and improvements can be anticipated. But even now, most limitations on the wider use of ODP equipment can be traced to shortcomings in the imagination of the user.

---

Test your retention

Here are questions based on the main points of this article. Their purpose is to help you make sure you have not overlooked any important ideas. You'll find the answers in the article.

1. How does the object-to-lens distance affect the location of the Fourier transform plane?

2. Why is the optical computer able to integrate faster than an electronic computer?

3. What factors determine the size and frequency scale of a model of an antenna array?

4. What is the principal advantage of optical correlation over its electronic counterpart?

5. Filters used for image enhancement are of what basic type? Why?
We’ve made life more difficult

Now you must choose between TWO automatic bridges

With the introduction of the 1681 Automatic Impedance Comparator, you are forced to decide whether it or the 1680 Automatic Capacitance Bridge is better suited to handle your measurement problems. You’ll thank us, though, because we’ve made life easier for you in the long run.

Whichever instrument you choose — 1680 or 1681 — you get a true three-terminal bridge, with all the inherent accuracy and stability of a bridge. You also get BCD output data, ½-second (or less) automatic balance, and a choice of frequencies (120, 400, or 1000 Hz).

Like the 1680, the 1681 can be used by itself or it can form the nucleus of an automatic measuring system. Systems typically include devices such as scanners, recorders, card- or tape-punches, and even on-line computers. Call your nearest General Radio Office, or write General Radio, W. Concord, Massachusetts 01781; telephone (617) 369-4400. In Europe Postfach 124, Ch 8034 Zurich 34, Switzerland.

**The 1681**
- Direct reading in impedance-magnitude and phase angle differences, and it can measure R, L, or C from 2Ω to 20 MΩ.

**The 1680**
- Direct reading in capacitance and dissipation factor (or conductance) over a 0.01-pF-to-1000-µF range.

**The 1681 achieves its flexibility through the use of external standards — precision laboratory standards or your production samples.**

**The 1680 contains its own highly stable internal standards.**

**The 1681 can read ΔZ to within 10 ppm of your standard and ΔΩ to within 0.00001 radian. Comparison accuracy is as good as 0.005%.**

**The 1680 reads absolute value of capacitance and loss factor to five-figure resolution at 0.1% basic accuracy.**

**The 1681 is best suited for comparison measurements or for measurements requiring extreme resolution. Typical applications are component evaluation such as temperature-coefficient measurements, receiving inspection, production testing, sorting, and precise measurement of small and low-loss capacitors.**

**The 1680 is best suited for general capacitance measurements where wide range, ease of use, and direct readout are desired. Capacitor sorting, process control, and quality control are typical applications.**
industrious

Small wonder the Clare LB Telephone Type Relay is kept busy—at 1.33 cu. in., it is unmatched for switching capacity and contact versatility—realistically priced!

You can design around 2 amp. to low level operation... using up to six Form C contacts... or Forms A, B, or D. Twin contacts assure reliable performance... with no adjustment needed. Use Type LB for direct pcb mounting... Type LBP for mounting with socket. With quality controlled manufacture and adjustment, you can depend on these industrious relays for consistent high quality... maintenance-free, long life operation.

For design information, circle reader service number—or ask Clare for Data Sheet 552B... Write Group 11A5.
C.P.Clare & Co., Chicago, Illinois 60645

- Long life: up to $50 \times 10^6$ operations
- Contact Versatility: 2 amp. to low level... twin contacts for reliability... up to 6 Form C with A, B and D available
- Stable, adjustment-free operation
- Socket terminals—pcb or solder

CLARE MINIATURE TELEPHONE TYPE RELAYS
for process control, computer peripheral equipment, communications, digital instruments, business machines, ground support equipment

INFORMATION RETRIEVAL NUMBER 32
Dual 100-bit MOS...
longest and lowest cost
static shift registers

- 200 bits per package
  ...for economy and
  reliability
- Lowest cost per bit
  (one-tenth bipolar
  registers)
- D-C to 1 MHz
  operation
  (no minimum
  clock rate)
- Extremely low power
  drain
  (1.5 mW per bit)

This is a photomicrograph of the
longest static shift register available in a production device today. It's the new dual 100-bit MOS-LSI from Texas Instruments...the latest of a growing family of computer-designed MOS circuits. Other static shift registers include dual 50-, 32-, 25-, and 16-bit units.

In addition TI is currently producing other advanced MOS circuits including memories...random access and read only, analog switching circuits, linear circuits, and custom logic arrays.

Furthermore, TI's computer design capability reduces design lead time for custom products tailored to your system needs.

A new MOS Static Shift Register Application Report is just off the press. For your copy—plus data sheets—write on your letterhead to Texas Instruments Incorporated, P. O. Box 5012, MS 980-C, Dallas, Texas 75222.

Texas Instruments
Incorporated
Unsnarl your complex wiring problems with computer-generated wiring lists. They're easy to develop and not prohibitively costly.

You are designing a relatively complex system, and the problem arises of drawing up a wire list for the many interconnections. You can do it manually, but it's drudgery. Why not use the company computer?

Great, except for one thing: The majority of engineering companies don't have access to costly sophisticated computer wire list programs. The solution: Seek out an amiable programmer in your company and, with his help, write your own computer wire-list program. Once you understand the basic technique, it can be adapted to most wiring requirements—and at a cost that's guaranteed not to bankrupt your company.

The function of the computer in these wiring-list tasks is to sort basic wiring-point information into alphanumerical lists of varying configurations and complexities.

More than one list used

The basic list and starting point from which the others are derived is called the Input Pin List (Fig. 1). It is simply the original, unsorted listing prepared by the designer to identify the points to be wired and the signals associated with those particular points. Each entry identifies the signal and its wiring point by code names. The makeup depends upon your requirements and the programming of your company's computer.

The unsorted pin list is put onto punched cards and entered into the computer. The computer then generates a Signal Wire List (Table 1) which connects all the wiring points in the input pin list that carry the same signal. This wire list is the most convenient method of indicating the numerous interconnections in a complex system. It presents, in tabular form, connections between all the components in a unit, such as connectors, switches and bus bars.

Each entry in the wire list is composed of a signal name and two points (FROM and TO) to which the wire is connected. Additional data, such as wire number, wire size, wire color, or even circuit loading information can be printed on the wire list. However, the more complicated the listing, the more closely the designer and programmer must work together. In fact, the programmer can be a valuable aid in organizing the initial list.
In Table 1 the computer has made a primary alphanumeric sorting of items according to the signal name, together with a secondary sorting according to the FROM location. This list is used during checkout and maintenance to find all points connected by a common wire.

For original wiring purposes, a Production Wire List, generated from the Signal Wire List in Table 1, sorts the items in the order in which they are to be wired, as shown in Table 2. The items in this particular list are first sorted according to the hardware areas shown in Fig. 2. Then, since the card rack area is to be wire-wrapped, the wire list is sorted according to the wire-wrap levels shown in Fig. 3. The Production Wire List thus permits each area to be wired independently, and it also gives the information for interconnecting the wires between areas.

For maintenance and checkout, a Location Pin List, generated from the Input Pin List, gives an alphanumeric sorting of items according to location, as shown in Table 3.

Generating the program

To produce a simple wire-list program, a set of arbitrary, consistent rules for wire routing must first be established, based upon the hardware configuration. For example, a representative unit (Fig. 3) consists of a front panel containing switches and indicator lights, a rear panel with input-output receptacles, and a card rack into which the printed-circuit card files are inserted.

The card rack is composed of columns of card files. Each file has a number of connectors (eight in Fig. 2), and each connector has connector pins. The card files are designated alphabetically, and the card connectors and connector pins are designated numerically. Thus the location of any point in the unit can be described by its card-file letter, its connector number and its pin number. For example, pin 14 of connector 01 in card file B in Fig. 2 is designated at BO1 14.

Note that in the wiring list (Table 1) it appears as B01 14 1. This last figure is the wiring level, which is 1 for soldered or taper-pin connections.

For wire-wrap connections, the location (or level) of the wire wrap on the connector pin is also included. For example, wire-wrap level 1 is closest to the connector (Fig. 3), level 2 is in the center level, and level 3 is on top. When wire-wrapping, it's best to alternate the levels (Fig. 3), so that a minimum of wires have to be removed when you make a change. To simplify programing, a wire-wrap level designation column is used throughout, even though only one area of a unit is to be wire-wrapped.

The physical location of connections to switches,

2. Complex wiring pattern is simplified by preplanning the wire routing and organizing the wiring areas, as shown in this representative example. Wires between the front panel and card rack are stranded; rest are solid.

lights, and input-output receptacles is handled in a similar fashion. Thus, “S” is a basic switch designation, and each switch is uniquely identified by a two-digit number that is the equivalent of a connector designation. For example: S03, Figs. 2 and 3. In this case, the switch has three decks, and the connection is made to terminal 2 of deck A. The complete location designator appears in the wiring list as S03 A2 1, since solder terminals are handled as “1” wiring levels by the computer program.

Wire routing rules

Having established the means of identifying connection-point locations, you next define the manner in which a single wire is routed between all the points that it connects. Once you determine this, you are in a position to draw up the wire-list program.

For the various interconnections, follow the philosophy of “high-high, low-low” routing, by routing all wires with the same signal name in the following way:

First, within a connector, route the wire from the pin with the lowest number to the pin with the next highest number, and so on. For example, in Fig. 2, wire between B06 03 and B06 12. A wire should enter a connector at the lowest pin number and leave it at the highest pin number with which the signal is associated.

Between connectors in the same card-file column, route the wire from the highest pin of the uppermost connector to the lowest pin of the next connector in line. (In Fig. 2, wire between B05 12 and B06 03.) Repeat this until all the connectors within the file are wired.

Between card files, route the wire from the highest pin of the highest connector in the first file to the highest pin of the highest connector in the next file to which the wire goes. (In Fig. 2,3)

</table>
wire between B08 16 and D06 17.) Then connect between the lowest pin of the lowest connector in the second file to the lowest pin of the lowest connector in the third file. (In Fig. 2, wire between A03 11 and B03 14). Repeat this high-high, low-low sequence until all card files are connected.

Assigning wire-wrap levels

When connecting a group of pins with wire-wrap terminations, join the first, third, fifth, etc., wires from level 1 to level 1 (Fig. 3). The second, fourth, sixth, etc., wires go from level 2 to level 2.

The last wire of the group always ends at level 1, with the following exceptions: To connect a stranded (front panel) wire to a wire-wrap pin, use a pin clip (Fig. 3, wire 0012)). This clip is attached to level 3 in the card rack or in the rear panel area. Where another wire is connected to the same terminal, wrap it on level 1.

Another exception to ending at level 1 is this: If one of two wires terminating in the card rack comes from the rear panel area, wrap it on level 2 (see Fig. 3, wire 0009).

Specifying the wire list

Once the wire routing rules are established, you are ready to go ahead with the actual specification of a wire list. Let's use the hardware, terminations and routing in Figs. 2 and 3, and represented by Tables 1, 2 and 3, as an example.

The particular wiring requirements for the unit represented by Figs. 2 and 3 are:
1. Wrap wires at card rack locations and at the input-output receptacles on the rear panel.
2. Solder wires at the switches and lights on the front panel.
3. Terminate wires from the front panel to the rear panel or card rack with a pin clip at wire-wrap level 3.
4. To minimize wire length, wire the elements in the sequence: S to A to B to C to D to J.
5. To facilitate production wiring, terminate wires from the rear panel to the card rack at wire-wrap level 2.

As a start, prepare an original list by designating signal names and the physical locations of all components to be connected, as well as the related terminals.

The original pin list that you generate will, in general, be an unsorted version of Table 3. It may not even be necessary to prepare the list if the information is presented on diagrams or in some format that can be easily understood by the key-punch operators.

Choosing a signal name

Note that the signal names in Tables 1 and 3 have eight alphanumerical characters. (For example: BGD29BBL). But this choice is purely arbitrary and will vary with the designer's own signal identification code, with the program requirements and with computer capacity.
In general, the first alphabetic group is associated with its signal function. The next two numbers refer to a particular circuit—for example, flip-flops. The last letters of the name may indicate the signal, its location, and any other association desired.

Let's dissect the BGD29BBL signal term, which, for this example, is concerned with the wiring of a computer. The principles can, however, be applied to any other type of circuitry.

In the BGD29BBL signal, the "BGD" indicates "buffer-gate driver" circuit. The "29B" reminds the designer that these circuits are driving buffer gate No. 29. The next (seventh) character "B" indicates the circuit type (buffer) in which the logic signal is formed, while the eighth term, "L," indicates that the level on that bus is "low" under conditions established by the designer.

To produce a wire list that follows these rules, you must add further inputs to the basic list. To minimize wire length, designate the routing sequence between files as well as the area where each card file is located.

It is most convenient and advisable to enter this information into the computer program prior to entering the input pin list data. The computer will then use this "pre-information" to generate a signal wire list that complies with wiring requirements.

In addition to the signal name, it is also desirable to have the wire-list program generate a different number for each wire on the list. These numbers aid in making any future wiring changes.

With the various elements entered into the computer program, the Signal Wire List of Table 1 is generated from the unsorted version of Table 3. The list is then re-sorted to generate the Production Wire List of Table 2. The actual wiring of the BGD29BBL signal term of Table 1 is illustrated in Figs. 2 and 3.

Revising the wire list

Changes are inevitable, and it is necessary to update the wire lists. The wire number identifies any wire that is to be changed. An example of the computer inputs needed to make such changes in the wiring lists is given by Table 4.

Here, the first entry shows how wire 0014 is deleted (from Table 1). The second entry indicates that the FROM location of wire 0010 is to be changed.

An example of how to add a new wire is given in the third entry. Note that no wire number is necessary, since once all these changes have been entered, the computer produces a new, updated list that includes the new wire number. When updating, it is desirable to have the computer program determine whether the designer has assigned two or more signal wires to one location, or possibly has assigned two wires to the same wire-wrap level. Such errors should be indicated on the Location Pin List is produced.

Since most wiring is involved with connections between four points or less, it is not necessary, in this simplified program, to provide absolute minimization of wire length—that is, those wire lengths that must be kept to an absolute minimum can be determined by the designer ahead of time and can then be optimized after the initial wire list is generated. The routing rules presented here provide for partial minimization of wire length between card files. However, the references below describe relatively complex algorithms, designed primarily to minimize wire length.

Only Magnetics Inc. gives you all three of these advantages in photo-etched parts:

1. Metals processed to your specification
2. Guaranteed magnetic performance properties
3. Total quality control, raw metal to finished part

There is nothing new about chemically milling small, thin metal parts. Dozens of companies can photo-etch any part that can be drawn. What sets Magnetics Inc. apart in photo-etching is our capability of processing the metal to close tolerances.

Magnetics' completely integrated production system for Photofab® parts is all-inclusive. We can custom blend basic metals into special alloys, or we can start with stock metal. We follow through with whatever it takes to match your specifications—precision rolling or flattening or strip annealing. As long-time specialists in magnetic materials, we have the facilities and the expertise needed to provide the ultimate in dimensional accuracies, at the same time guaranteeing the magnetic properties of your parts.

We augment our production capabilities with uptight quality control. This means the most advanced laboratory and test equipment, manned by a staff of nit-picking experts. When you take delivery on Photofab parts, you can be sure that they've passed our constant surveillance, from basic metal through shipment in custom-designed packaging.

If you've been looking for a supplier who can offer single-source responsibility on photo-etched parts, you've found us. For more information, write Magnetics Inc., Dept. ED-104, Butler, Pa. 16001.
90-second look at IEE's wonderful world of readouts

Readouts are our special craft. Using any characters you want. Any colors or color combinations. Any input, BCD or decimal. Any input signal level. Any mounting, vertical or horizontal. Five sizes, up to 3½". Many configurations, options and accessories. Long lamp life (to 100,000 hours; up to 175,000 hours at reduced voltage). If it doesn't exist and you need it, we'll build it.

10H—World's most popular readout. And we've improved it. Double condensing lens provides exceptional character brightness. Greater clarity at wider angles and longer distances, even under high ambient light. .937" sq. viewing area. Mil-spec version available.

120H—Miniature rear-projection readout (.62" sq. screen) easily read from 30' under high ambient light. Quick-disconnect lamp assembly speeds lamp replacement.

160H—Exceptionally large viewing area (1.56"H x 1.12"W) for overall size. 45 FL character brightness with a 6.3V 5.20 lamp. Displays messages simultaneously with symbols.

80—Large screen unit suited for annunciator applications such as factory call systems and production control. 3½" character height can easily be read at 100'. 160° viewing angle.

875—Miniature 24-position readout assembly with a cost per display of only $1.45 each. .620 sq. in. viewing area with overall case size of 1.39"H x .90"W x 3.095"D. Exceptional brightness, clarity. Front panel access.

IC Driver/Decoders — Small, reliable units for driving IEE readout incandescent lamps ranging from 250 ma @ 6V to 40 ma @ 28V. Fully compatible with modern IC's. Accept a variety of binary codes for decimal conversion. Require normal signal V., draw less than 2 ma per data input. Internal data storage for pulsed oper.

345 — IEE's smallest rear-projection readout. Viewing area .38"H x .34"W. Based lamps. Low cost. Individual readouts plug into perm. wired housing for quick message change. Easy front panel access.
Until now, designing with mercury relays meant taking the good with the bad. The trade-off for long life, high-speed closure and no contact bounce has been a bulky package (about \( \frac{3}{4} \) cu. in.) that must be babied in a vertical position.

**But not any more!** Now Logcell® Mercury Film Relays offer all the advantages of mercury-wetted relays... plus miniature size (0.06 cu. in.), operation in any mounting position, and shock and vibration resistance suitable for many airborne, marine and other mobile applications.

Whether you require the specific advantages of mercury relays for computer logic circuits, advanced instrumentation or high-speed control systems... or just need a tiny rugged relay that will last and last and last, consider Logcells:

- Long life — units tested to billions of cycles
- No contact bounce
- Operation in any mounting plane
- Form "C" SPDT contacts
- Fast operating time — 2 ms
- No measurable AC contact noise
- Thermal noise less than 0.2 microvolt
- Switches dry circuits to 2 amps at 0-6 volts
- Inherent contact memory — requires no holding current (mono-stable models also available)

For complete information about revolutionary new Logcell Mercury Film Relays — and Logcell Mercury Film Switches—write Fifth Dimension Inc., Box 483, Princeton, New Jersey 08540 or call (609) 924-5990.

**IN ANY POSITION**
Simplify selection of the critical resistor in TTL common-collector OR drivers. Generate graphic aids with the formulas given here.

In the design of TTL common-collector OR drivers, resistor selection can be complicated. The value depends on three interrelated factors which together can yield nine different combinations, each affecting the choice. But the selection can be simplified with the help of formulas and graphs.

A versatile type of IC output logic is a so-called “floating collector” array that can be connected to provide the “wired-OR” logic (Fig. 1) for driving data busses. But a problem arises if the collectors are connected directly to the following gate (Fig. 2a). While transistor $Q_0$ can be turned on to provide a logic 0, it cannot be turned off to assume a logic 1 state without adding a “pull-up” resistor, $R_p$.

But selecting this particular resistor can be an involved process because its value depends upon three interrelated factors: (1) the number of outputs wired together; (2) the number of gates that are driven; and (3) the value of the pull-up resistor itself.

Selection of $R_p$ is simplified by use of the formulas and graphs developed here which establish maximum and minimum limits between which $R_p$ can lie.

The maximum allowable value of the pull-up resistor depends on three factors: the value of $V_{ce}$, the leakage current, $I_{CEO}$, of the driving stage in the OFF condition, and the leakage current of the driven gate, $I_{LS}$, as shown in Fig. 2b.

The minimum value of $R_p$ is limited by the maximum (saturated) current capability of the driving transistor ($I_o$) and the load current, $I_a$, of the driven gate.

For the single driver-gate combination shown by $Q_n$, $Q_o$ in Fig. 2b, the maximum value of $R_p$ is determined by the formula given, provided $Q_o$ is off and its collector voltage is at its highest, or “1” level. Note that the driver leakage current $I_{CEO}$ is the only current assumed for the collector, which means that the input of $Q_o$ is not at a threshold condition.

The minimum value of $R_p$ for the single driver-gate combination is obtained from the formula shown in Fig. 2c. In this case, the $Q_o$ collector current is at its saturated value, which includes the current $I_{po}$ through $R_p$, plus the $Q_o$ gate load current, $I_g$.

In actual application, the designer is interested in determining the boundary values of $R_p$ for $n$ driving stages and $m$ driven gates, as indicated in Figs. 3 and 4. In general, note that each driver in the bus must be able to independently drive $m$ gate loads. For these problems, the equations of Figs. 2b and 2c now become:

$$R_{p\,\text{MAX}} = \frac{(V_{cc} - V_{1\,\text{MIN}})}{[n\,(I_{CEO}) + m\,(I_{LK})]}$$

$$R_{p\,\text{MIN}} = \frac{(V_{cc} - V_{0\,\text{MAX}})}{[n\,(I_{SAT}) - m\,(I_{d})]}$$

These equations may be solved and reduced to useful graphs, on which a range of values for $R_{p\,\text{MAX}}$, $R_{p\,\text{MIN}}$, $n$, and $m$ are directly presented.

As an example, specification limits of a standard SUHL circuit will be applied:

$V_{cc} = 5.0\,\text{V}$
Logic 1 voltage minimum, $V_{1\,\text{MIN}} = 3.0\,\text{V}$
Logic 0 voltage maximum, $V_{0\,\text{MAX}} = 0.4\,\text{V}$
Logic 0 current minimum, $I_{SAT} = 10\,\text{mA}$
Driver leakage current, $I_{CEO} = 250\,\mu\text{A} = 0.25\,\text{mA}$
Driven gate input leakage, $I_{LK} = 100\,\mu\text{A} = 0.1\,\text{mA}$
Gate load current = 1.33 mA

The general equations now become:

$$R_{p\,\text{MAX}} = \frac{(5.0 - 3.0)}{[n\,(0.25) + m\,(0.1)]}$$

$$R_{p\,\text{MIN}} = \frac{(5.0 - 0.4)}{[10 - m\,(1.33)]} = 3.45/(7.5 - m)$$

With these equations, plots of sample calculations for logic circuits having a maximum driving transistor current $I_{SAT}$ of 10 mA and a gate load current $I_{d}$ of 1.33 mA were made. They are presented in Fig. 5. The upper left-hand curve is the boundary on the minimum value of pull-up resistor $R_p$, for the specified driver/gate characteristics.

---

**Electronic Design** 23, November 7, 1968
1. Floating-collector outputs of "wired-OR" TTL logic are connected together to drive logic gates.

2. Simple connection of driving collector to driven gate (a) gives unreliable operation. Addition of "pull-up" resistor $R_p$ is required for positive turn-off of $Q_0$. Maximum value of $R_p$ is derived from (b), minimum from (c).

3. Current flows are multiplied as drivers and gates are added during maximum-value conditions for $R_p$.

4. Saturation $I_s$ and gate ($I_g$) current flows for determining minimum value of $R_p$. 
The vertical curves, designated \( n_1, n_2, \text{etc.} \), are the maximum-value boundaries for \( R_p \).

Once the number of collectors to be connected to the same bus is determined—for example, \( n = 4 \)—the maximum value of \( R_p \) may be determined by traversing the \((n = 4)\) line to that point at which it crosses the desired number of \( m \) driven loads. The minimum value of \( R_p \) may be determined for the above conditions by traversing the horizontal line to the point at which it intersects the upper boundary, designated as 1.33 mA.

For example, assume that four drivers are connected to the same bus and three gates are driven from this bus. At the intersection of the \((n = 4)\) and \((m = 3)\) lines, in Fig. 5, the maximum value of \( R_p \) is found to be 1.57 k\( \Omega \). Traveling horizontally to the left of this intersection, we find the minimum value of \( R_p \) where the \((m = 3)\) line intersects the lower resistance boundary. In this case, it is 730 \( \Omega \).

Should it be desired to increase the number of driven gates from three to four (with four drivers), then maximum \( R_p \) becomes 1.45 k\( \Omega \) and the minimum 1.0 k\( \Omega \). If the number of drivers is increased to six \((n = 6)\), the curves show that no more than three gates may be driven under the previously specified conditions.

Note that a second curve for a gate current \( I_d \) of 1.66 mA is included as a second example of typical gate requirements. Values of \( R_p \) are determined for this curve as before.

A sample plot of values obtained for gates with the same current requirements as in Fig. 5, but with a single driver current capability of \( I_{\text{sat}} = 40 \text{ mA} \), is shown in Fig. 6.

**Test your retention**

Here are questions based on the main points of this article. Their purpose is to help you make sure you have not overlooked any important ideas. You'll find the answers in the article.

1. What resistor is required to provide reliable turn-off operation of wired-OR drivers?

2. What is the formula for maximum value of this resistor? For minimum value?

3. How are basic formulas altered when numerous drivers and gates are connected in the circuit?

4. What determines boundary areas of maximum and minimum-value plots for \( R_p \)?
By habit, precision jobs got wire wounds.

Until Corning.

Now, you have another choice.
A less expensive choice.
Glass tin oxide film.
Corning makes them.
In the precision range,
Makes them with a base of pure optical glass. And a fully oxidized metal film.
Environment can't degrade either. Film and substrate are molecularly bonded. Matching TC's do away with fatiguing stresses. Special silver-glass composition insures low termination noise.
Press-fitted end caps mean mechanical integrity. Tailored tough insulations wrap them up. It all adds up to long-term reliability.

General purpose, precision, or special, CORNING® Glass Tin Oxide Film resistors are a better buy—by design. From 1/10 watt in .150", up to 6000 watts in six feet, they're all shown in our new Resistor Design Guide.

Opportunities for CIRCUIT DESIGNERS

Expanding activity on long-range programs and advanced projects has created many stimulating growth-assignments for Circuit Designers at Hughes.

Some of our most urgent requirements exist in the following areas:

- Development of high-power airborne radar transmitters, the design of which involves the use of the most advanced components
- Design of low-noise radar receivers using parametric amplifiers and other advanced microwave components
- Design of digital radar signal processing subsystem circuits, including range and speed trackers, doppler filter banks and a variety of display circuits
- Design of high-efficiency power supplies for airborne and space electronic systems
- Development of telemetering and command circuits for space vehicles and communications satellites

Requirements: an accredited Engineering degree, a minimum of two years of directly relatable experience and U.S. citizenship.

For immediate consideration, please airmail your resume to:

Book Reviews

second edition

HANDBOOK OF PHYSICS

prepared by a staff of specialists

Physics handbook

A massive volume of some 1600 pages, the second edition of the Handbook of Physics is a major revision of this standard work. The combined effort of scores of experts in their respective fields has contributed to the success of this and past editions. Completely updated, the book presents authoritative information on all aspects of physics in its 92 chapters and offers the latest findings, theory and data. An extremely thorough 64-page index gives immediate access to information contained in the nine major sections into which the volume is divided. Since physical laws are the basis on which engineering science is built, this volume can serve the engineer as well as the physicist.

CIRCLE NO. 321

Product planning plan

Long on the Concept side of its title, Short on the Practice side. Hardly a how-to-do-it for the man

History-making toy

The toy gyroscopes Elmer Sperry bought for his children inspired his invention of the Sperry gyro-compass and gyro-stabilizer—-for naval vessels and early-day aircraft.

Sperry-developed equipment helped Lindbergh, Wiley Post and Amelia Earhart achieve their history-making flights. Many other aviation "firsts" also came from Sperry.

Today, Sperry's contribution to the safety and comfort of Jet Age pilots and passengers—civilian and military— is the greatest of any company in the world. In fact, in production of flight controls, flight instruments and displays, we lead our nearest competitors by a wide margin. We are also pacemakers in aerospace products.

If you're an engineer — and want to give your career new excitement and significance — we'd like to hear from you. These are our current requirements:

- Instrument Displays
- Auto Pilots
- Compass Systems
- Circuit Design
- Advanced Avionics
- Gyroscopics
- Mechanisms
- Magnetics
- Standards
- Product Support
- Research & Development
- Manufacturing Engineering
- Industrial Engineering
- Publications
- Logistics

At our Greenville Division it's Oliver Kirby.

If you're considering a career move, consider LTV Electrosystems. You'll be working with men of his caliber.

Once the assistant director of the National Security Agency in charge of worldwide operations and planning, Mr. Kirby now heads up advanced planning for the largest of our four operating units.

Intelligent planning and a "can do" attitude has helped propel LTV Electrosystems into the big time in electronics. 1966 sales hit $123 million. Last year, a record $181 million. 1968 promises to be another record year.

Our main line is electronic systems—the "total package" concept developed for special mission requirements for land, sea, air and space deployment. With people like Oliver Kirby, we've done a great job for our customers. This has generated a number of outstanding career positions—particularly for talented systems experts.

Current systems programs include surveillance and reconnaissance, tracking, command and control, tactical warfare, communications, TACAN, guidance, antennas, super-power transmitters. We also design and produce much of the hardware for these systems and we manufacture many lines of standard electronic products.

Presently we are hiring specialists in artificial intelligence, RF systems analysis, RF circuits design, digital systems analysis, digital circuits design, radar systems analysis, electrical systems installations design, optics systems and aerodynamics.

What's ahead for LTV Electrosystems? Oliver Kirby is working on it. So are planners in all our divisions. We'd like you to join us and participate in our growth and our future.

Please write or call Bill Hickey, Supervisor of Professional Placement, P.O. Box 6118, Dallas, Texas 75222. Tel. (214) 276-7111. An equal opportunity employer.
McDonnell Douglas is involved in a number of exciting programs that, for the moment at least, are marked “X”. These include FX, VFX, and AX. And each one requires experienced electrical/electronics engineers to help us turn “experimental” into “operational.”

Specifically, we now need engineers specializing in these areas:

- Acoustic data processing
- Radar Systems
- Electronic Countermeasures
- Airborne antennas & radomes
- Inertial navigation systems
- Transmitter-modulator
- Digital computers
- Infrared
- Electro-magnetic compatibility.

We’re also staffing up in other disciplines for our new DC-10, STOL transports, AWACS, and for new missile systems and manned spacecraft programs.

Long-term career openings are immediately available in St. Louis, Southern California, Florida, and Texas. Just put “X” in the appropriate box in the coupon to indicate your preference.

Then send it today, along with your current resume if available, to arrange for an interview.

---

**BOOK REVIEWS**

who finds he’s suddenly down to the nitty-gritty of product planning and has “gotta come up with something.”

The author, who has been involved in electronic product planning as a Vice President of Lenkurt Electric Co., Inc., for the last 12 years, is a strong exponent of assigning product planning responsibility to an individual on a full-time basis. And full-time it well might be under his comprehensive concept of closely involving technical, financial, marketing, manufacturing, legal, and personnel operations in the product planning process.

The technical manager examining titles in search of product planning guidance may question the aptness of a reference which devotes a full 20 percent of its text to “Technical Manpower Planning” and ranges therein from manpower inventories to leadership development.

*Bruce Trabue*

**CIRCLE NO. 322**

**Engineering handbook**

This is the Golden Anniversary edition of a venerable standby that has gone through seven editions in the past fifty years. Although, as its title implies, it has been compiled for mechanical engineers, it richly deserves a place on the shelf of electronics men as well. Chapters on electrical engineering, electronics, instruments, cryogenic, automatic controls, and optics are directly relevant to the electronics field and many others are of interest to all engineering disciplines. Those sections aimed directly at the mechanical engineer can also be useful, in view of the interdisciplinary nature of many of the fastest moving areas of engineering today. A large, comprehensive index of over 100 pages serves as an effective key to the vast storehouse of information contained in this massive volume.

**CIRCLE NO. 323**
Now! Get 225 MHz for less than $2K and add 3.3 GHz for less than $1K!

But how does the competition look?

GREEN!

Who else offers a counter that provides frequency measurements up to 225 MHz for only $1975, plus the options of two plug-ins to boost the range to either 1.3 GHz for $775 or to 3.3 GHz for only $825? That's what you get from CMC with the Model 616 Counter and the new Models 631 and 635 Heterodyne Converters. But that's not all.

Look at the rugged portable design of the CMC Model 616, with its sturdy valise grip and its solid well-balanced frame. Here's an instrument that's equally at home in the lab, on the production line, or in the field. You can rack mount it, too. And its all-silicon solid-state circuitry gives it an extended operating range from -20°C to +55°C.

Already a popular workhorse, the 616 is in common use for alignment of frequencies in UHF communication links, for calibration of high frequency signal generators, for direct monitoring of radio/TV transmitter carrier frequencies, and for production checkout of radio transmitters. But now, with the addition of two great heterodyne converters—and a TIM plug-in if you want it—here's a low-cost, portable family that's hard to beat for application versatility!

For the full specs on the counter and plug-ins, just circle the reader service card. And to arrange for a demonstration, contact your local CMC representative.
Sawtooth generator provides millivolt discharge level

Sawtooth output is provided by the controlled charging and discharging of capacitor C.

In voltage comparator design, a sawtooth generator with good linearity and a discharge level of only a few millivolts is frequently needed. These requirements are achieved in the circuit shown.

Operational amplifier A₁, together with \( R₁ = R₂ = R₃ = R₄ \), acts as a current source, with the capacitor, C, as its load. When C exceeds the voltage determined by \( +V_s \times R₅/(R₅ + R₆) \), comparator A₂ causes chopper transistor Q₂ to go into saturation (through emitter follower Q₁). This discharges C to the millivolt level of the Q₁ saturation voltage. Besides its good linearity and millivolt discharge level, the circuit offers simplicity, since integrated circuit operational amplifiers are used. In addition, no circuit adjustments are required.

N. Freiman, Research Engineer, Ministry of Defense, Tel-Aviv, Israel.

Adjust amplifier gain with an op-amp

The ac gain of an amplifier often needs to be adjusted with great accuracy. One way to do this is to measure the input and then monitor the output while performing the gain adjustment. But this method has its shortcomings:

- Adjusted gain will be a function of the accuracy of the meter used to measure input and output. Scale-to-scale accuracy of an ac meter is rarely better than a few per cent.
- Unless two meters are used, the stability of the signal generator becomes a factor (the input must be trusted to remain constant between the...
The Compatibles

NEW Helipot Model 841 Miniature 4-bit Ladder Switches feature:
- unipolar or direct bipolar operation
- 350 nanosecond rise and fall time
- 0 to 2 millivolt switch offsets (at 25°C)
- 5 (±3) ohms "on" resistance
- 0 to 5 milliamps output current
- small size (1" x 1" x 0.170" high)
- cermet thick film construction
- list price, $100.00
- available from stock

Helipot Series 811 Precision, High Speed Binary Ladder Networks feature:
- up to 1/2 bit accuracy in 12 bits from −55° to +125°C or from −20° to +80°C
- 50 nanosecond settling time
- 1 ppm/°C tracking
- small size (1" x 1" x 0.1" high)
- cermet thick film construction (assuring ultrastability and minimum change in performance with time)
- list prices from $27.00
- available from stock

The Helipot Compatibles are designed to give you—pre-engineered and pre-packaged—a ladder system with the combination of economy, sophistication, small size, and flexibility you can’t get anywhere else. Check out The Compatibles from Helipot—for complete specifications, ask your local Helipot sales representative or circle the reader service number.
Amplifier gain can be adjusted very accurately by detecting the zero voltage at the output of the op-amp. The use of two meters provides a check on input constancy, but introduces meter-to-meter error.

- It is difficult to adjust a voltage more precisely than a few per cent while shooting for a specific reading on a meter face.

Using an operational amplifier in the circuit shown eliminates all these inadequacies. The principle of operation is as follows. Assume that the gain of the amplifier under adjustment is in error by and amount $X$, so that the amplifier output is $A(1 + X)V_{in}$. The values of $R_1$ and $R_2$ are chosen to yield a voltage divider with the ratio $A$. If a perfect divider ratio is assumed, the output of the voltage divider is $(1 + X)V_{in}$. The operational amplifier is connected as a differential amplifier with gain $K$. The voltage at the "monitor" terminal is therefore $KXV_{in}$. When the correct value of $A$ is attained in the amplifier under adjustment, the voltage at the "monitor" terminal will go to zero. It is thus possible to adjust the gain of the amplifier very accurately by the simple act of nulling a sensitive ac meter at the "monitor" terminal.

The only significant sources of error in this scheme are:

- Accuracy of the divider resistors $R_1$ and $R_2$. This poses no serious problem; resistors of $\pm 0.1\%$ and better are easily obtainable.
- Loading of the divider by the differential amplifier input impedance, which is equal to $(1 + K)R$. This can be minimized either by using the largest practical values of $K$ and $R$, or it may be taken into account in selecting the values of divider resistors $R_1$ and $R_2$.
- Loading of the amplifier, under adjustment by the $R_1$, $R_2$ voltage divider. This is minimized by choosing the highest practical values of $R_1$ and $R_2$.

This gain adjustment scheme is independent of signal generator stability, is easy to implement, demands no great meter accuracy, and combines the capability of gain adjustment with extremely good resolution.

Cure voltage and temperature ills in inverted chopper switches

In analog-to-frequency converters using choppers, transistor voltage drops and temperature variations constitute major sources of error. Here is a circuit (see schematic) that can circumvent them. It operates as follows.

$Q_1$ and $Q_2$ serve as chopper transistors, alternately connecting the outputs of amplifiers 1 and 2 to the input of the integrator on the alternate half-cycles of the square wave from the bistable switch. Amplifier 2 has a gain of $-1$ and the resultant square wave at the emitters of the choppers is symmetrical. Its magnitude is dependent on the levels at the outputs of amplifiers 1 and 2. The switching levels of the bistable switch are fixed.

Identical inverted switching transistors are added in the feedback loops of the amplifiers ($Q_3$ and $Q_4$), introducing an opposing offset voltage.

Voltage drops and temperature variations in a voltage-to-frequency converter are nulled out with the addition of $Q_3$ and $Q_4$. These transistors are the same as the chopper transistors $Q_1$ and $Q_2$.

IDEAS FOR DESIGN

to the chopper transistors. Any changes in temperature in the chopper transistors are met by opposing changes in the compensating transistors. These transistors should be biased ON to the same level as the chopper transistors in their ON state.

This circuit approach is used in a voltage-controlled function generator.

The slope of the output from the integrator is dependent on the values of $R$ and $C$, and the polarity and magnitude of voltage applied to the integrating resistor. The bistable switch has fixed firing points of ±2.5 V. Therefore, when the output of the integrator reaches ±2.5 V, the bistable switch functions to change the polarity of the voltage applied to the integrator. The same occurs when the integrator output reaches —2.5 V.

The bistable switch output turns on $Q_1$ when negative and $Q_2$ when positive. In this way, the outputs of the two operational amplifiers are alternately connected to the integrator. The first amplifier has its gain adjusted for a given frequency outlet for an applied voltage. The gain of the second amplifier is set to unity. The magnitude of the square wave applied to the integrator thus is determined by the voltage levels at the outputs of the two amplifiers, and is set by the level of the positive voltage applied at the input. Since the other frequency-determining factors are fixed, the voltage at the input terminal determines the output frequency of both the triangle and square-wave outputs.

Jerry F. Foster, Chief Engineer, WAVETEK, San Diego, Calif.

VOTE FOR 313

Simple solid-state circuit detects frequency

Here is a circuit that can detect a given frequency and put out a signal whenever this frequency is applied to the input (see schematic). The frequency detectable by this circuit is determined by the values of $L$, $C$, and $R$.

While the circuit was originally designed to detect 40 kHz, it can detect other frequencies by changing $L$, $C$, and $R$. With the values shown, the circuit detects 19 kHz, the frequency of the so-called stereo beacon.

Here is how it works. The first stage, $Q_1$, a frequency selective amplifier, is followed by a detector, $D_1$. The feedback path, $R_1$, assures fast response of the output stage, $Q_1$, and an increased sensitivity.

A sensitivity (adjustable with $R_1$) of better than 10 mV was obtained over the “capture bandwidth” of 1 kHz. It can be increased by adding another linear amplifier stage at the input.

The pilot light used as a load for the output stage can be replaced with a relay coil or other compatible load.

W. P. Beullens, Design Engineer, Louvain University, Institute of Low Temperature & Applied Physics, Leuven, Belgium.

VOTE FOR 314

A 19-kHz detector has a sensitivity of 10 mV over its “capture bandwidth” of 1 kHz. In order to detect 40 kHz, $L$, and $C$, must be changed to 4.5 and 3300 pF, respectively. Operation otherwise is the same.
4½-Digit DVM. Compact flexibility: $1150.

We've packed a lot of flexibility into our Model 7000 DVM. It's only half-rack size (5¼" x 8¾" x 12"), but has five big options: auto-ranging, AC volts, resistance, DC current and BCD output. Options are contained on convenient plug-in circuit boards. A front-panel function switch controls all options. The 7000 is built with integrated circuits and provides a reading accuracy of 0.01%. Resolution is 100µV. Input impedance is greater than 1000 megohms. You also get dual slope integration, automatic polarity and display storage. Low power operation means no fan and no noise. A 7000 DVM can be yours in 15 days. You can get our data sheets even faster. Write today.
Lamp and photoresistor adjust loop bandwidth automatically

A photoresistor and an incandescent lamp provided a simple solution to a tough phaselock problem that came up during the Mariner Venus 67 project. The problem was to provide a spectrally pure 1.0 MHz signal from a remote rubidium frequency standard, for use in some precision ranging experiments. Because the reference signal from the standard had to be transmitted through space, it became degraded. A phaselock "cleanup" loop (Fig. 1) was designed to extract the clean signal from the noise.

One difficulty posed by this approach was that a very narrowband loop (0.02 Hz) was needed to provide this extremely pure signal. However, a bandwidth so narrow is difficult to hold, and, when lost, very difficult to regain. The time required for phaselock with an initial offset of only 0.03 Hz, for example, was calculated to be 67 minutes, because of the slow rate of scan necessary. This time would be cut down dramatically if the bandwidth were increased. Merely opening the bandwidth to 0.08 Hz when the loop is unlocked, and then decreasing the bandwidth logarithmically toward 0.02 Hz upon achieving lock, cuts the acquisition time from 67 minutes to less than 30 seconds, for a 0.03 Hz offset.

In an application such as the Mariner Venus probe, this bandwidth variation must be done automatically.

Photocell to the rescue

The problem is solved by placing a photoresistor across the bandwidth-determining resistors, R1 and R2, of the loop filter (Fig. 2), and a light source, L1, near it. If for any reason the loop loses lock, a relay in the lock detector places +28 V on R4, activating the transistor circuit (Q1 and Q2) which, in turn, activates the light source. Until this point, the lamp is completely off. With the light on, the photocell resistance changes from more than 300 MΩ to less than 2 kΩ. This removal of power from the light source must be done at a very gradual rate and as smoothly as possible so that the loop remains in lock. It requires approximately 3 minutes; this slow decay makes the use of a FET mandatory.

The quartz oscillator used in this loop was a precision instrument intended for use as a frequency or time standard. In actual measurements, the loop bandwidth was determined to be 0.021 Hz when locked to a local rubidium frequency standard.

The operational performance of this system was proved last October when the Mariner space vehicle passed within 2500 miles of the planet Venus.

R. B. Crow, Senior Development Engineer, Jet Propulsion Laboratory, California Institute of Technology, Pasadena, Calif.
The Bourns Model 3111 TRIMPOT® Relay is a high performance, 1.0 ampere, DPDT unit that answers the demand for higher reliability and greater miniaturization. It is hermetically sealed in a 1/6 crystal can, with convenient 0.1" grid pin spacing.

The Model 3111 has an operating temperature range of -65 to +125°C. Contact rating is 1.0 ampere resistive at 28 volts D.C., with a pickup sensitivity of 130 milliwatts. Operate and release time is 4 milliseconds maximum. This model also features a self-damping return spring and balanced armature design assuring excellent shock (50G) and vibration (20G) performance. All requirements of MIL-R-5757 are met or exceeded by the Model 3111. And its price is just $13.34.

For further data and detailed specifications, contact your nearest Bourns sales office or representative, or write the factory direct.

IDEAS FOR DESIGN

Line synchronized pulse unit triggers microcircuits

With most digital microcircuits, a very sharp pulse is required to assure proper operation. When it is necessary to operate from a sine-wave source, such as the 60-cycle line, it takes a lot of wave shaping to get a pulse sharp enough to trigger the microcircuits.

The circuit described produces pulses having rise times that are fast enough to trigger any microcircuit flip-flop. The operation is based on a General Electric device, the D13T1, called a Programmable Unijunction Transistor.

The D13T1 operates somewhat like an SCR. No current flows through the D13T1 until the voltage on the anode exceeds the voltage on the gate by approximately 0.5 V. The device then exhibits the typical 4-layer negative resistance action.

In this circuit, the zener diode and resistor \( R_1 \) produce a waveform that is approximately square from \(-0.6 \text{ V} \) to \(+12 \text{ V}\). When the voltage goes to \(+12 \text{ V}\), capacitor \( C \) charges through resistor \( R_2 \). The voltage on the gate of the D13T1 follows the zener voltage, while the anode voltage is delayed slightly by the RC time constant of \( R_2 \) and \( C \).

As long as the voltage on the anode is not positive with respect to the gate, the D13T1 continues to act as an open circuit.

When the input to the circuit drops below \(+12 \text{ V}\), the gate of the D13T1 follows the decrease. The anode, however, is held to approximately \( 12 \text{ V} \) by the charge on the capacitor. When the difference voltage from gate to anode becomes 0.5 V or higher, the D13T1 breaks down and switches to the hard ON condition. Capacitor \( C \) then discharges through resistor \( R_4 \), developing the output pulse.

The D13T1 cuts off as soon as the capacitor is discharged, since there is no other source of sufficient current to keep it conducting. In this way, one positive pulse of about \( 4 \text{ V} \) amplitude and 10 \( \mu \text{s} \) width is produced for each cycle of input. Two pulses per cycle could be produced by applying full-wave rectified voltage to the zener.

The diode in series with resistor \( R_2 \) keeps capacitor \( C \) from tending to discharge when the input voltage drops, and thus assures the highest output pulse.

VOTE FOR 316

Two op amps provide floating output circuit

Outputs from equipment are sometimes required to be floating—not related to a supply or ground level. For ac signals, a convenient solution is to use an isolating transformer. Dc outputs, on the other hand, must first be chopped and then rectified again after passing through an isolating transformer. But because miniaturization of these approaches is difficult, neither is consistent with an integrated-circuit philosophy.

A circuit that can produce a floating output for both ac and dc signals, without need for a transformer, is shown in the illustration. It employs two operational amplifiers, such as the \( \mu A709 \), and, as shown, is interconnected so that the differential output \( C-D \) is equal to inputs \( B-A \). If only one signal exists, the other input terminal can be connected to ground.

Either output lead can be connected to ground, or to any voltage level within the output range of the ICs without damaging them or disturbing the differential output relationship.

M. Stevens, Staff Engineer, Cossor Electronics Ltd., Aviation Products Div., Harlow, Essex, England.

VOTE FOR 317

Floating output provided at \( C-D \) has the same magnitude as input \( B-A \).

Michael R. Leibowitz, Electronic Engineer, Brooklyn, N.Y. His Idea "Get better performance from a parallel-transistor stage" has been voted the Most Valuable of Issue Award.

Cast your vote for the Best Idea in this Issue.
Better circuit testing requires better pulse generators.

Better check these out.

The Hewlett-Packard 8002A and the Model 8003A Pulse Generators offer you new and improved control over your input pulses for testing circuits under actual operating conditions. With clean, well-controlled and clear geometry pulses, you now have a versatile way to analyze circuit outputs without being restricted by the limitations of the pulse generator itself.

The 8002A Pulse Generator gives you excellent control of your pulses, with rise and fall independently controllable by means of a vernier. Variable rise and fall times, 10 nsec to 2 sec, and rise/fall, fall/rise ratios up to 30:1. Repetition rate is 0.3 Hz to 10 MHz. 50 ohm source impedance, even during transitions; reflections are minimized. Price: $700.

For the best pulses and greatest versatility for your money, the 8003A Programmable Pulse Generator is your best buy. Here you get simultaneous positive and negative outputs, 5 nsec rise time, pulse width of 30 nsec to 3 sec and a 10 MHz repetition rate. Great for fast switching applications, wide frequency testing capability of the 8003A also makes it ideal for testing analog devices such as wideband amplifiers, filters and other linear circuits. Price: $470.

If you've been searching for a better way to test circuits, a way to get better, more accurate results, get complete details on these two pulsers by calling your local HP field engineer. Or write Hewlett-Packard, Palo Alto, Calif. 94304; Europe: 54 Route des Acacias, Geneva.

Microwave synthesizer with counter-like accuracy provides spectrally pure signals from 1 to 12.4 GHz. Seven digital switches resolve frequencies in 10-kHz steps. Page 102

Also in this section:

Photoconductor arrays come in custom-designed configurations. Page 116
Chip zener diodes for 1.8 to 91 V offer four assembly choices. Page 116
Design Aids, Page 146 . . . Application Notes, Page 148 . . . New Literature, Page 150
Microwave synthesizer has extended range; generates stable signals at 1 to 12.4 GHz

Clean and coherent signals at frequencies to 12.4 GHz can now be digitally selected at the front panel of a new laboratory instrument. Where synthesizers have up to now been limited to 2.4 GHz, this instrument synthesizes sinusoidal waveforms in 10-kHz increments over four ranges that span the L, S, C and X bands.

With the introduction of this unit, frequency synthesis can be applied to solving design problems at substantially shorter wavelengths. Applications foreseen by the manufacturer include frequency-standard calibration, use as a local oscillator in broadband microwave receivers, and use in military automatic test sets.

The system's coherence and low noise will facilitate the testing of high-frequency narrow-band fm receivers used by the military for voice communications. For microwave communications, frequency synthesis can help solve the spectrum-space dilemma.

Employing indirect (phase-lock) synthesis techniques, the new instrument achieves a stability of $1 \times 10^{-9}$ per second and $1 \times 10^{-6}$ per day; with the use of a more accurate 1-MHz external source, stability can be extended by three orders of magnitude. Power output is 50 mW at frequencies below 4 GHz and 30 mW above 4 GHz. Non-harmonically related signals are 60 dB below the selected frequency; harmonics are at least 20 dB down. Phase noise measured in a 1-kHz band, centered 30 kHz from the selected signal, is down at least 65 dB.

Operation of the model 300A synthesizer is extremely simple. Once connections have been made to a suitable external VCO (such as Micro-Power's 221-11 sweeper), output frequency can be set in 10-kHz increments by seven digital switches provided on the front panel. External digital programming can be applied at each decade through 4-wire BCD inputs. Positive indication that the instrument is locked on the correct frequency is given by a front-panel indicator lamp, which makes it virtually impossible for false frequencies to mislead the user.

To employ the full range of the instrument, four back-panel plug-ins are required. Model 301A covers 1 to 2 GHz; model 302A, 2 to 4 GHz; model 303 A, 4 to 8 GHz, and model 304A, 8 to 12.4 GHz. Operable on either 115 or 230 V ac, at 48 to 420 Hz, the package measures 19-by-5-1/4 by 20-in. deep.

Choose the exact DC output you need. Singles or duals. Regulated or unregulated. Whether you need one power supply or several, your order will be shipped in just three days! That's our promise. For your copy of our latest catalog, contact your local Acopian rep, call us at (215) 258-5441, or write to Acopian Corp., Easton, Pa. 18042.
L-band delay line loses only 50 dB

While operating at 50-W peak power in L band, a microwave acoustic delay line with a 10-μs delay exhibits a loss of only 50 dB. In S band, its loss is 65 dB; in C band, 90 dB. The unit is designed per MIL-E-5400.

Custom Wound Bobbins and Special Coils

Custom wound bobbins are now available in an extensive range of inductance values and current ratings on many standard forms. Where space limitations dictate one or more dimensions, Miller engineers will make recommendations to help you obtain optimum performance in your circuit.

Screened room with precision test equipment assures close tolerance measurements for special coil characteristics. Intensive specialization in coil design and manufacture assures excellent operating results with a high degree of reliability.

“Guide to Better Coil Selection” describes major types of windings and advantages of each type; gives 10-point check list of primary considerations for use when selecting inductors. Write for your copy today.

For your bobbin and special coil requirements, call a Miller coil design specialist—(213) 233-4294.

Miniature LC hybrid shrinks attenuator size

Without degrading performance, an electronically controlled coaxial attenuator achieves miniaturization through the use of a lumped-element quadrature hybrid. About the size of a match head, the hybrid is an LC network that allows the attenuator to maintain constant impedance, no matter where the attenuator is set. Known as Pellet, the QHU-2-K hybrid functions independently of wavelength, unlike its distributed-component counterparts. This is the second time that Merrimac Research and Development has used the ultra-miniature network in an assembly.

Balance-mixer units were the first. The new attenuator, model AEM-2-2.2K, is about one-half the size of currently available comparable units and weighs only 1 oz. It has a center frequency of 2.2 GHz, but special versions can be supplied with center frequencies from 1 to 3 GHz. Its attenuation range covers 0 to 18 dB.

Satisfying the military’s demand for smaller size, the miniature unit is expected to offer particular advantages for the aerospace and satellite applications of telemetry, radar and communications. Other uses are automatic signal leveling and control, a-m modulation, and remote signal control.

The AEM-2-2.2K can be modulated at any frequency up to 2 MHz. It accepts a maximum input signal of -15 dBm and requires a control current from 0 to 0.5 mA.

Other specifications include a bandwidth of 10% and an attenuation variation of ±5% with fixed bias. Insertion loss is 0.65 dB. VSWR is 1.5, and rf impedance is 50 Ω.
PACT cuts losses in latching microstrip circulators 80% in twelve months

Engineers at work in Sperry’s PACT (Progress in Advanced Component Technology) Program have announced outstanding success in an intensive 12-month campaign to cut insertion losses of external loop latching microstrip circulators.

When the effort began, the loss figure was 2.5 db at X-band; today, Sperry has built external loop latching circulators with insertion loss of only 0.5 db at the same frequency.

PACT’s latching circulator work actually began with an internal loop configuration. YIG substrates were prepared with loops of .005” and .010” platinum wire fired in place. Test data were taken at substrate thicknesses of .100”, .075” and .055”. Results showed that, while fixed bias performance improved as thickness decreased, other factors caused latching performance to deteriorate.

EXTERNAL LOOP X-BAND LATCHING CIRCULATOR, WITH LATCHING PLATE AND SUBSTRATE SHOWN SEPARATELY

Since temperature and high power stability are prime design parameters, the program settled on a design using .482” square x .055” thick hybrid YIG substrate. Lithium ferrite — a material with saturation magnetization of about 3500 gauss, a coercive field of 2.0 oe, and a very square hysteresis loop — was chosen for the latching plate. The switching loop was four turns of #24 copper wire.

Using this configuration, PACT engineers have achieved switching times of less than 1 microsecond, with performance as indicated in the accompanying curve.

INTERNAL LOOP X-BAND LATCHING CIRCULATOR

While the test results obtained with the internal loop device were generally satisfactory, PACT engineers felt that the configuration had some inherent disadvantages. Among these were difficulty and expense of fabrication, and unsuitability for use in modules. This led to extensive investigation of the external loop design.

PACT personnel found one immediate advantage: when working with external loop, they could consider the substrate and the latching plate independently. Intrinsic and physical properties of the substrate material could be chosen for good microwave performance, while latching plate design need only consider hysteresis and other switching parameters.

For further information about PACT work on latching microstrip circulators and their coming application in microwave IC’s, contact your Cain & Co. Representative, or write Sperry Microwave Electronics Division, Sperry Rand Corporation, Clearwater, Florida.

For faster microwave progress, make a PACT with people who know microwaves.

MICROWAVES & LASERS

Frequency system uses standard units

Consisting of standard, general-purpose instruments which can be used separately for other tasks, type E40-5245L digital frequency measurement system operates with a transfer-oscillator technique from dc to 40 GHz. The instruments in the new system are: an electronic counter, a local oscillator, a synchronizer for phase-locking the local oscillator to cw input signals, a mixer, a 20-dB directional coupler, and a monitor tee.

CIRCLE NO. 252

Dielectric foam sheets are flexible or rigid

Available in either flexible or rigid sheets, Eccofoam H1K artificial foam has essentially constant dielectric properties through the microwave frequency band. Standard dielectric constants range from 1.1 to 6. Loss tangent increases with increasing dielectric constant from 0.001 to 0.031.

CIRCLE NO. 253

Portable pulse supply drives laser diodes

Laser Diode Laboratories, Inc., Metuchen, N.J. Phone: (212) 867-6062.

Driving injection laser diodes at room temperatures, a portable, solid-state, pulse power supply provides a 100-A output current with rise and fall intervals of 50 to 100 ns. Model LP11 has two triggering modes, an internal one with a continuous variable repetition rate ranging from 100 Hz to 1 kHz, and an external one allowing manual operation at repetition rates below 100 Hz.

CIRCLE NO. 254

Step-recovery diode multiplies frequency

Designed primarily for use as a frequency multiplier in microwave systems, a step-recovery diode features efficiencies as high as 76% when doubling from 1 to 2 GHz. In other frequency conversions, the FGC1001 exhibits an efficiency of 55% when doubling from 4 to 8 GHz, and 57% when quadrupling from 1 to 4 GHz. The new diode operates with transition times of only 100 ps.

General Electric introduces the smallest 50mw, 2-amp relay on the market

Tiny, powerful and turned on with the touch of a feather

This extra-small, 2-pole, 2-amp relay needs only the slightest tickle to operate—50 milliwatts. With this impulse, it performs standard high-level output switching from low-level, microelectronic input.

Sizewise, it’s only 0.32” high, 0.31” wide, and 0.61” long. And, it meets or exceeds all MIL-Spec environmental and electrical requirements of relays many times larger.

Because of its low operate power and size, this relay is ideally suited for microelectronic applications. Its low profile lets you stack many more circuit boards in the same space.

Like all General Electric 150-grid relays, this new 50mw type is available with a number of options to suit your individual application. You have a choice of coil ratings for a wide range of system voltages, a choice of popular mounting forms and header types.

If this new relay tickles your fancy, contact your General Electric Electronic Components Sales Engineer, or write for Bulletin GEA-8589, Section 792-43, General Electric Company, Schenectady, New York 12305.
McLEAN
Solid State Temperature Controller

Modulates the Flow of Cool Air Within a Very Narrow Thermal Range

This new system employs a transistorized control and a modulating thermostatic probe to sense critical component temperature or outlet air temperature. Together these modulate the speed of the blower automatically supplying the right volume of air to maintain constant thermal stability. The Controller is preset so that the blower begins to operate at 80°F increasing in output as the temperature rises. Full output is achieved at 90°F. REQUEST DATA SHEET SSC 700.

FEATURES:
- Maintains cabinet temperature between 80°F and 90°F
- Automatically modulates blower speed
- Systems stay drift-free
- Quieter operation
- Extends life of electronic components
- Extends blower life
- Costs less than air conditioning
- More compact than air conditioning

High-frequency characteristics are now specified and guaranteed for new transistor chips designed for microwave hybrid microcircuits. In addition, these transistor chips (35800 series) have microwave characteristics that allow use in critical oscillator and amplifier applications. Typical f<sub>r</sub> is 3 to 4 GHz with typical f<sub>max</sub> going as high as 6 GHz.

CIRCLE NO. 256

Crystal mixers operate at 90 GHz

Scientific-Atlanta, Inc., P.O. Box 13654, Atlanta, Ga. Phone: (404) 938-2930. P&A: $600; 4 wks.

Improving sensitivity by using X band as the fundamental mixing frequency, series 17 microwave crystal mixers cover the frequency range of 26.5 GHz to 90 GHz. They are cross-waveguide units with adjustable cavity plungers for both the X-band fundamental input and the millimeter-wave input. The plunger tuning provides both fast course adjustments and fine micrometer settings for adjusting resolution of the mixer cavity.

LIKE A SURE THING?

THE ODDS ARE 36,000 TO ONE COHU HAS THE RIGHT TV SYSTEM FOR YOU! A pioneer in TV, Cohu today is the largest producer of standard, off-the-shelf TV systems in the industry. Take the standard lenses, camera controls, pick-up tubes (both vidicons and Plumbicons®) and video monitors—put these together with Cohu’s various camera housings, remote controls and lens drives and you have over 36,000 possible TV system combinations. And this does not include Cohu’s wide variety of quality TV accessories and switching systems.

ONE IS RIGHT FOR YOU! Whether your needs be industrial, educational or military, one of Cohu’s TV combinations is right for you. Let Cohu engineering know-how design for you a custom TV system from standard, off-the-shelf components.

For details on the industry’s most complete TV line, contact your nearest Cohu representative or call Bob Boulio direct at 714-277-6700 in San Diego. The odds are in your favor.

Box 623, San Diego, California 92112. TWX 910-335-1244.
We’ve just cracked the vacuum-tube rectifier market.

Now Varo has developed a new series of High Voltage Fast Recovery Diffused Silicon Rectifiers economically competitive with both vacuum tubes and selenium. And they mean improved reliability in color and monochrome receiver applications.

Peak reverse voltage rating for the series is from 5,000 Volts to 45,000 Volts, with rated output current to 25 milliamps. And we can supply you with any shape you need. In sizes from .250” square and 1.00” long. Diode-capacitor voltage multiplier assemblies are also available.

This new series is the result of Varo’s continuing R & D leadership in high-voltage rectifiers.

Varo is the same company that introduced miniature, low-cost high-voltage diodes for night vision applications; the Integrated Bridge Rectifier (IBR®) and the Epoxy Integrated Bridge Rectifier (EBR).

If you’d like to give your customers all the advantages of totally solid state TV circuitry, now you can.

In the meantime, don’t feel bad if you’re still using vacuum-tube rectifiers.

Up until now, it was the only choice you had.

For complete details, applications, and price list write or call.

INSTRUMENTATION

Compact panel meters display D/A data

Two new panel meters, which combine analog and digital read-out in the same package, display three full digits plus 100% over-range with a full-scale accuracy of 0.1%. Analog display is performed with 5% resolution by a lit needle that uses a horizontal row of 20 neon lamps to simulate the left-to-right action of an ordinary deflection-type meter. Two models are available, the 700 and the 710 with floating BCD output.

CIRCLE NO. 258

Audio test system combines 4 in 1

Operating from a battery supply, a portable, solid-state, audio test system combines four basic instruments into one. Model 140 consists of an rf/i-f/af signal tracer, a tone generator, a multiple-input audio amplifier, and an oscilloscope preamplifier. The system is designed not to overload or damage transistors. Gain is 70 dB, noise is -60 dB, and frequency response is ±3 dB.

CIRCLE NO. 259

One-hand test probe makes three contacts

Requiring only one hand to make three simultaneous touch-to-test contacts, the model FP-3 probe tests transistors, diodes, and other compact components mounted on printed boards. It has three spring-loaded needle-point tips that tilt or swivel on ball joints for adjustment to any spacing from 1/32 to 5/8 in. Three leads, color-coded to their respective tips, terminate in insulated alligator clips for easy connection to the test instrument being used.

CIRCLE NO. 260

Digital clock/calendars use integrated circuits

Designed to provide digital display of time and date for data processors and computers, series 30,000 digital clock/calendars employ full IC construction to lower price tags and to reduce package size. Offering over 7000 combinations of options, the new units require only 1-3/4 in. of panel height, at either half-rack or full-rack width. Standard-time display is 8421 BCD; real-time units are optional.

Socket to 'em!

We make subminiatures so they’re more subminiature.

Smaller. Lighter. More fully packed. 110 contacts to the inch, without sacrificing contact size or spacing.

It happened like most Hughes innovations. We couldn’t find connectors small enough for our space jobs—so we made some small enough. Rugged enough.

That was the birth of PolarHex, our center jackscrew coupling mechanism. It insures perfect alignment, positive engaging and polarizing.

Hughes subminiatures also feature crimp snap-in contacts with the industry’s best retention system. The retaining clip is anchored to the contact, not the body—so it floats free for easy alignment.

They’re available in environmental, non-environmental and potting versions. In arrangements to fit any requirement, from 14 to 244 size 22 contacts.

If you’re up tight for space, write and say “socket to me.”

Write Hughes Aircraft Co., Connecting Devices, 500 Superior Ave., Newport Beach, California 92663. Phone (714) 548-0671. TWX 714-642-1353.

Connecting Devices, part of Hughes Circuit Technologies. Including: Contour™ Cable; Semiconductors; Flip Chips/Equipment; Frequency Control Devices; Microelectronic Circuits; MOSFETs.

If it’s happening in connectors, it probably started at Hughes.

Plug-in modules
alter panel meters

Philbrick/Nexus Research, A Tele-
dyne Co., Allied Drive, Dedham,
Mass. Phone: (617) 329-1600.
Price: $65 or $90.

When attached to the back of a
panel meter, plug-in modifiers
change current devices to voltage
devices. There are two basic types
of Meter-Mates: a high-impedance
unit and a log-null unit. The high-
impedance unit converts a 50-µA
low-impedance meter into a high-
impedance 0.1-mV voltmeter. The
low-impedance unit expands a scale
logarithmically for sensitive, ac-
curate null readings.

CIRCLE NO. 266

Digital panel meter
has 0.01% accuracy

California Instruments Corp., 3511
Midway Dr., San Diego, Calif.
Phone: (714) 224-3241. Availabil-
ity: 30 days.

Featuring 5-digit Nixie readout
and automatic polarity indication,
a digital panel meter provides an
accuracy of 0.01% and a resolu-
tion of 0.008%. Model 8361 oc-
cupies only 2 by 3-1/2 in. of panel
space, 5-1/4 in. deep. Standard
full-scale ranges cover ±12, ±120
and ±1200 V. Nominal input im-
pedance is 10 MΩ, and common
mode rejection is 100 dB.

CIRCLE NO. 267
Why take pot luck for reliability?

The Daystrom Squaretrim 318-160HS with pins, and the new Model 313-160HS with flexible leads are both designed, manufactured and tested in complete accordance with MIL-R-39015. This means you no longer have to resort to costly unmonitored programs when you need high reliability potentiometers. These new Squaretrim models not only give you the best design and materials, but are manufactured with piece part traceability, in-process controls, and the stringent QC program defined in this Specification. So... our advice to you is: don't trust to luck. Specify and order Daystrom Hi-Reliability Squaretrim pots. They're available in values from 10 ohms through 20K. Prompt delivery on orders. Write or phone today, Daystrom potentiometers are another product of: WESTON COMPONENTS DIVISION, Archbald, Pa. 18403, Weston Instruments, Inc., a Schlumberger company.
LENZ MAKES THEM ALL... AND MORE!

No matter how sophisticated the system or how simple the device, Lenz can provide the necessary cables . . . quality-built, reliable, compact!

Lenz engineers have a broad knowledge of electronic equipment and complete familiarity with the environmental, electrical, temperature and mechanical characteristics of the wires and cables required.

Having a cable problem? Pass it along—Lenz will help find the solution, with no obligation, of course!

INFORMATION RETRIEVAL NUMBER 57
It has been computed that "debugged" DM30, 10,000 MMF units, when subjected to 257,000 hours of life at 85°C with 100% of the rated DC voltage applied, will yield only 1 FAILURE PER 43,000,000 UNIT-HOURS!

DM15, DM16, DM19, DM20 . . . perfect for miniaturization and for new designs using printed wiring circuits. Also available in DM30, DM42 and DM43.

New "hairpin" parallel leads insure easy application. Exceed all electrical requirements of military specification MIL-C-5A.

Available in 350 voe and 500 voe as well as voltages.

All bases are of low-loss steatite.

Special lugs are obtainable for printed circuitry.

Miniature units are available.

Solder Lugs can be bent in any position without affecting the capacity setting due to the rigid construction.

Various types of mounting brackets are available for all trimmers.

Units can be constructed for special applications.

Life tests at 105°C with rated voltage applied have yielded only 1 FAILURE PER 1,433,600 UNIT-HOURS for 1 MFD. Since the number of unit-hours for these capacitors is inversely proportional to the capacitance, 0.1 MFD Mylar-Paper Dipped capacitors will yield only 1 FAILURE PER 14,336,000 UNIT-HOURS!

Working volts DC: 200, 400, 600, 1000 and 1600.

Tolerances: ± 10% and ± 20% (closer tolerances available).

Dielectric strength: 2 or 2½ times rated voltage, depending upon working voltage.

Exceed all electrical requirements of E.I.A. specification RS-164 and military specifications MIL-C-91A and MIL-C-25A.

*Registered Trademark of DuPont Co.

Unmatched for excellent stability, dielectric strength, high insulation resistance, extremely high "Q" and correspondingly low power factor.

Units can be subjected to a short "debugging" life test at elevated voltages and temperature. Exceed all electrical requirements of E.I.A. specification RS-164 and military specifications MIL-C-91A and MIL-C-25A.

NEW/ FROM NORTRONICS

FIRST COMBO HEAD FOR 8-TRACK STEREO
MODEL Z-B2L

ELIMINATES:
ASSEMBLY TOLERANCE,
TRACK ALIGNMENT AND
PRESSURE PAD PROBLEMS

This new Nortronics Z-Combo head—a major engineering accomplishment—reduces the spacing between erase and playback gaps from the conventional .250" to an extremely small .050"!

Because of the close tolerances required in 8-track stereo, the conventional gap-to-gap spacing creates serious problems. A 1° azimuth correction of the R/P gap in conventional combo heads creates a vertical displacement of .004" of the erase gap. As a result, the erase gap may incompletely erase the proper tracks and at the same time erase wanted material on adjacent tracks. With the Nortronics Z-Combo heads, the equivalent displacement is less than .001°.

The new head also permits simplified circuitry in the recorder, since it features internal automatic biasing.

The new Z-Combo head displays the quality, engineering, ingenuity, and responsiveness to every recording need that have made Nortronics the world’s largest manufacturer of laminated core tape heads and the standard-setter for the industry.

Complete technical data is available on request.

ICS & SEMICONDUCTORS

Overvoltage monitors accept 10-A surges

Requiring only a low standby current, hybrid cermet overvoltage monitors protect power lines with an adjustable triggering speed and a 10-A peak surge capability. They can be used for direct control in a shunt mode or for indirect control along with SCRs. They handle 4-A continuous current and 11-W power. Series 826 has threshold points from 8 to 40 V, and series 827 covers the 5-to-7-V range.

ICS & SEMICONDUCTORS

Pnp power transistors carry 1 A at 300 V

Motorola Semiconductor Products, Inc., P.O. Box 20924, Phoenix, Ariz. Phone: (602) 273-6900. P&A: $12 or $15; stock.

Pnp silicon power transistors, the 2N5344 and the 2N5345, are capable of carrying a collector current of 1 A when collector-to-emitter voltage is 250 and 300 V, respectively. Both transistors are fast switches with a maximum turn-on time of only 200 ns at 500 mA and 100 V. Their high-voltage rating permits direct 117-V line operation without step-down transformers.

CIRCLE NO. 274

Low-level amplifier has beta of 500

Fairchild Semiconductor, 313 Fairchild Dr., Mountain View, Calif. Phone: (415) 962-2530. P&A: $2.40; stock.

Operating from dc to radio frequencies, a pnp low-level amplifier provides current gains from 50 to 500 at 10 μA and a maximum noise figure of 4 dB at 1 kHz. Type 2N4359 has a minimum collector-to-emitter breakdown voltage of 45 V and a low leakage current of 10 nA. It is supplied in a TO-18 metal can.

CIRCLE NO. 275
Our general purpose relays aren't known as the least expensive. But they have earned the reputation for reliability with the most consistent performance record of any general purpose relay on the market.

In addition, Magnecraft has more general purpose relays in stock than anyone else. This means nearly all your requirements can be filled in days—if not hours. As for variety, we have it over the others with relays such as our improved Class 88KD 50 ampere relay that's ideal for industrial switching applications. And the new Class 88LCP Latching Relay that's composed of two Class 88 Relays with interlocking latching levers mounted on a common base and a crack-proof polycarbonate cover.

If all this doesn't overcome price alone, better forget us. But if you want large silver cadmium oxide contacts, precision hinge-pin armature bearings, molded nylon bobbins and overall custom made quality, then keep us in mind for all general purpose relays. Ours outclass the others at any price.

A-to-D Converter

Pastoriza offers the first utility converter for systems applications... priced for quantity sales.

Having first introduced the modular A-to-D and D-to-A converter, Pastoriza Electronics now offers an unprecedented innovation: A printed circuit card A-to-D converter featuring...

High Performance
- 12 bits conversion in 8 microseconds.
- 10 bits conversion in 4 microseconds.
- 8 bits conversion in 2 microseconds.

Low Cost
Priced competitively with any ADC available today, and designed for volume production.

Open Book Concept
No black magic in the design — circuitry is accessible and repairable.

User Confidence
Design and component information is supplied to insure ease and confidence in customer application.

This complete single-card A-to-D converter includes reference supply and comparison amplifier, using dual in-line integrated circuit logic with a MINIDAC D-to-A module. It accepts 0 to +10 volts input range, and provides up to 12 bits resolution.

Write for eye-opening facts on this newest modular A-to-D utility converter.

DATA PROCESSING

D-A binary ladders settle in 50 ns

Binary ladder networks with a maximum settling time of 50 ns convert data from digital to analog to within one-half the least significant bit. Available in five resistance values from 1 to 10 kΩ, series R-2R operates over the temperature range of −55 to +125°C. Standard resistance tolerance is 5%, but 1% units are available. The networks are supplied with standard DIP mounting pins.

Glass tape reel does not deform

Corning Glass Works, Optical Products Dept., Corning, N.Y. Phone: (607) 962-4444.

Eliminating many of the problems that plague recording equipment, this glass tape reel will not warp or bend even under extreme environmental conditions. Its glass flanges cannot be dented; when squeezed together, they will return to shape immediately. Because of this reduction of flange deflection, tape edges and recorded data on the tape are protected. The smoothness of the glass flanges also serves to minimize tape-edge wear and damage.

A-D converter module allows bipolar output

Analogic Co., 296 Newton St., Waltham, Mass. Phone: (617) 891-4708. P&A: $275; stock.

Model AN2200-AVS plug-in module permits true bipolar operation of A-D converters that provide only complementary output codes for bipolar inputs. With a ±10-V step input, the module settles to 0.01% of its final output amplitude in 2.5 μs. It has a high transfer accuracy of 0.005% full scale, over the temperature range of 0 to 70°C.

INFORMATION RETRIEVAL NUMBER 64

Electronic Engineering Co. of Calif., 1601 E. Chestnut Ave., Santa Ana, Calif. Phone: (714) 547-5501. P&A: $86 to $250; stock.

Thirteen new digital logic cards use TTL ICs to operate at speeds as high as 10 MHz. Types D-4201 to D-4213 expand the EECoLogic 2 line to 64 cards. Included are J-K flip-flops, multiple-input NAND gates, retrigerable one-shots, inverters, a shift register, dual binary and BCD counters, a NAND buffer, and a 4-bit digital magnitude comparator.
Both available from distributors for immediate delivery

These standard models offer outstanding specifications...lowest priced conductive plastic...immediate delivery.

The 3438 and 3501 Conductive Plastic potentiometers are another indication of the depth of the Bourns line. Other models, non-linear and linear and with or without load compensation, available to your specific requirements including MIL-R-39023. If your needs call for a single-turn or a ten-turn...Bourns has the solution! Before you specify or buy just any conductive plastic units, take a good look at the 3438 and 3501.

Get all the data you need for a sound decision. Write today for the latest catalog sheets or call your local Bourns office, representative, or stocking distributor.

New MINIDAC High-Speed D-to-A Converter in a small package

- 3/4" x 3/4" x 1 1/2"
- No Switching Transients
- Low Price

MINIDAC is an extremely versatile, UHF Digital-to-Analog converter module designed for driving into 100 ohm matching impedance. It may also be used with Operational Amplifiers for greater voltage ranges. These modules accept RTL, DTL or TTL input signals, include reference, switching, resistors, and provide currents of up to 10 ma. into resistive load.

Output voltage time constant is less than 30 nanoseconds and will settle to 0.1 % in 200 nanoseconds. An external threshold adjustment permits user to adjust the actual switching threshold minimizing the variations in rise and fall times in his logic. Feed through of switching signals has been eliminated.

APPLICATIONS
High Speed Scope Deflection Systems
Time Compression
High Speed A/D Converters
Precision High Speed Test Circuits

MINIDAC units are available in up to 12 bits Binary or BCD input codes, and current output ranges of 4 and 10 ma. Maximum output voltage without amplifier is 2 volts. Custom designed D/A Converters including Buffer Storage and special output Amplifiers are available upon request.

DATA PROCESSING

Fast A-D converter resolves 15 bits

Electronic Engineering Co. of Calif., 1601 E. Chestnut Ave., Santa Ana, Calif. Phone: (714) 547-5501. P&A: $6000 to $7000; 60 days.

Intended as a direct computer input and for analysis of rapidly varying analog information, a high-speed A-D converter completes 250,000 conversions per second with a resolution of 15 binary bits. Model 1200 can be supplied with a single input or with an integral 4-channel multiplexer. It is isolated from other circuits to minimize noise pickup and to insure stability.

CIRCLE NO. 280

Transmission system varies data speed

Lenkurt Electric, Sub. of General Telephone & Electronics, 1105 County Rd., San Carlos, Calif. Phone: (415) 591-8461.

Designated the 25B, a low-speed data transmission system uses passive plug-in filters to vary channel spacings and data speeds from 120 Hz for 75 bits/s to 1.02 kHz for 600 bits/s. The new system will operate over most types of transmission facilities including cable, open-wire and microwave-multiplex systems, and microwave supervisory channels. It can be arranged for either 2- or 4-wire circuits.

CIRCLE NO. 282

Nylon-mesh filters clean computer air

Nylon Filter Corp., Dept. EI-2, 932 W. Huron St., Chicago. Phone: (312) 321-0200.

With a nylon mesh of 44-to-48-micron fineness, a new line of air filters protect computer information storage systems from dust and contaminants. Compared to other types of filters, these permit freer airflow while performing their filtering function. Several styles and sizes are available, including the flat disc and frustum types used in disc packs.

CIRCLE NO. 281

A-D converter has dual output

Theta Instrument Corp., 22 Spielman Rd., Fairfield, N.J. Phone: (201) 227-1700. P&A: from $300; 30 days.

Using dual-slope integration, an analog-to-digital converter, which accepts inputs of 0 to 1 V dc, produces simultaneous BCD and decimal outputs. Conversion speed is 10 ms with a maximum sampling rate of 50 readings/s. Full-scale accuracy is 0.1 %, and input impedance is greater than 100 M$. 

CIRCLE NO. 283
Two
Very Handy
Alfred Detectors

10 MHz to 12.4 GHz
± 0.5 db Response
SWR Less than 1.5

Providing a full-range flat frequency response of better than ±0.5 db, SWR of less than 1.5 and high sensitivity, new broadband Crystal Detectors ALFRED Models 1001 and 1002 are ideally suited to many applications, including:

**Power Leveling.** The flat frequency response of the Model 1001 coupled with ALFRED Directional Couplers provides precise power leveling to ±0.3 db over octave bandwidths.

**Power Measurements.** The low SWR and exceptional stability of the Model 1001 permit accurate, long-term power measurements.

**Broadband RF Detection.** Characteristics of RF devices may be accurately displayed as a function of frequency using an oscilloscope or XY plotter and an Alfred sweep oscillator.

**Reflectometer Measurements.** The exceptionally uniform crystal characteristics provide the matched frequency and square law response required for reflectometer measurements.

**Video Response.** Output capacitance is low (approximately 30 pf) for outstanding video response.

**BRIEF SPECIFICATIONS**

- Frequency Range: 10 MHz - 12.4 GHz
- Frequency Response: ± 0.5 db full range
- SWR: Less than 1.4 to 10 GHz and 1.5 to 12.4 GHz
- Sensitivity (no load): Power input required to produce 0.1 v rectified output—no greater than 0.4 mw
- Square Law Response: Within ±0.5 db, low level to 1 mw input when properly terminated
- Maximum Input Power: 100 mw
- Dimensions: 2.4” long x 0.8” diam.
- Connectors: Input, Model 1001 Type N, and Model 1002 OSM; output BNC
- Price: $115 with BNC, $160 with OSM Connector

For complete details, ask your local ALFRED representative or contact us at 3176 Porter Drive, Palo Alto, California 94304. Phone (415) 326-6496.
**PRODUCTION**

**Hot-air gun shrinks plastic**

The Leister hot-air welding gun simplifies precision heating of shrinkable-plastic encapsulating and molding materials. Working temperatures at the nozzle range from 68 to 1112°F. Temperatures are governed by a six-stage switch on the handle which also contains the blower.

CIRCLE NO. 284

**Compressed-air gun neutralizes static**

3M Co., 3M Center, St. Paul, Minn. Phone: (612) 733-1590. Price: $69/year.

By supplying ionized air, the 902 portable air gun blows away dust and neutralizes static electricity in one operation. The barrel of this compressed-air device contains a nuclear source that ionizes air as it is blown out of the gun. Ready to be attached to an air line, the standard model is equipped with a 1/8-in. orifice, coupler plug, and a hose end.

CIRCLE NO. 285

**Portable pump kit transfers liquids**

Miller-Stephenson Chemical Co., Route 7, Danbury, Conn. Phone: (203) 743-4447.

A portable miniature pump kit uses an aerosol-type propellant to transfer liquids from one container to another. Porta-pump consists of an aerosol can fitted with a special valve head, a graduated 250-in.³ plastic bottle, and a length of plastic tubing. The valve head provides either pressure or suction, as desired, to expel or pump a liquid between the bottle and another vessel. Both actions can be controlled to an accuracy of one drop.

**SLIDE-TROL®—NEW CONCEPT IN POTENTIOMETER DESIGN**

- Mount horizontally, vertically or sideways, either singly or in multiple units.
- Standard solder lug, wire wrap or printed circuit terminals available.
- Low noise and low contact resistance, plus uniform heat distribution.
- Ratings 40-500Ω, 1.5 watts, 500-5kΩ, 1.25 watts, 5kΩ and over 1 watt.
- Thermal expansion-contraction and shock hazard problems eliminated.
- Know resistance setting at a glance.
- Compact, lightweight, functional, attractive.
- Write for SLIDE-TROL® Brochure.

CIRCLE NO. 284

**UNIQUE DESIGN ADDS VALUE AND APPEAL**

- 23 rocker switch configurations, including 2-3 positions, spring return and center-off.
- Variety of rocker designs available in a spectrum of colors and hot-stamped lettering.
- Listed by UL and CSA, 1 to 10 amps at 125V AC.
- Solder lug, space saver, quick-connect or printed circuit terminals.
- Field-proven quality same as famous Stackpole slide switches.
- Prices start at less than 15¢.
- Write for engineering literature.

CIRCLE NO. 285

**ENVIRONMENT PROOF ROTARY SWITCHES**

- Both index mechanism and electrical sections are completely enclosed.
- Corrosive atmospheres, dust, dirt and moisture are permanently sealed out, lubricants sealed in.
- Solder or quick-connect terminals molded permanently into position minimize production damage.
- Standard index angles include 15°, 30°, 36°, 60° and 90°, special angles available on request.
- Write for engineering bulletin.

Sidney Corn Enterprises, 1317 Third Ave., Los Angeles. Phone: (213) 985-1228. Price: $4.95 or $6.95.

For drawing horizontal, vertical, or angular parallel lines in automatically measured distances, two double-scaled calibrated drawing/drafting rulers combine a T-square, a rolling ruler, and a special plastic triangle with metal roller. The Speedliner ruler has scales in 16ths and 10ths of an inch, and scribes circles and arcs to diameters of 22 in. The Linemaster ruler, which has an outrigger bar, draws a variety of lines in measured distances in a single continuous unbroken line.

Handheld cutters hold snipped wires

Dentronix Corp., P.O. Box 237, Cornwells Heights, Pa.

A feature called Shear-Hold permits stainless steel cutting pliers to retain cut wires in the jaws. All cutting edges are high-speed tool steel, inserted and finished by hand for each tool. Tip alignment is continuously maintained by box joints.

Step and repeat system has 80-µ in. accuracy

Royal Zenith Corp., 2101 Jericho Turnpike, New Hyde Park, N.Y. Phone: (212) 421-7800.

Designed for the reproduction of film and integrated circuits, Mistic 102 step-and-repeat system delivers a dimensionally stable contact print with excellent definition even at the periphery. It is capable of producing minimum steps of 0.001 in. with a guaranteed accuracy of 0.00008 in. The system features a precision camera with a fixed focus lens for 10× reduction in an independently suspended chassis.
New WETREED Relays eliminate reed bounce or chatter in microvolt or power switching ranges

Hathaway's new mercury-wetted reed relays give super-reliability wherever low level data is important

Hathaway's new WetReed Relays undergo the same exhaustive production lot pre-testing that has made our DriReed line so successful. Hathaway takes extra steps to make sure the relays we ship are really reliable. Each lot performs to our exacting standards or the whole batch is scrapped.

Telemetry instruments, data control, test equipment—wherever high-speed chatter-free switching is mandatory, Hathaway has the new WetReed Relay with lot-proved reliability for you. Write for the complete Hathaway WetReed Catalog.
PACKAGING & MATERIALS

Portable air spray dusts confined area

Miller-Stephenson Chemical Co., Inc., Route 7, Danbury, Conn. Phone: (203) 743-4447.

Called Extend-Air, a new aerosol source of pressurized air removes dust and other particles from hard-to-reach places in delicate assemblies. Its valve and extension nozzle are connected to the can by a length of plastic tubing. The aerosol propellant forces air to the valve where it is controlled by the user with simple fingertip pressure. One Extend-Air provides up to 30 minutes of continuous air spray.

Plastic clasp bites to lock

Useful for a variety of electronic and industrial applications, a polypropylene clasp with interlocking teeth accommodates a wide variety of wire bundle diameters. Called the Hugger, the clasp is available in two sizes. These are supplied with self-adhesive backing or are predrilled for attachment with staples, nails, or screws. It is resistant to corrosive acids and caustic materials, and withstands temperatures to 225°F.

What can you do with a blower motor offering up to 7 stages and 3 psi?

With speeds up to 7500 rpm for the WINDJAMMER 9.5 Belt-Driven Blower, and an "airpower" range as wide as the one shown below?

You can obviously solve a wide range of air-moving problems, and fit these solutions exactly to your requirements. Which is just what Lamb Electric's new WINDJAMMER Blower line is designed to do. A stock of standard modular components allows Lamb Electric to build just the power system you need by adding stages (up to seven), with a choice of motor windings, face or foot mountings plus important optional features. These modular components are already engineered and tooled to eliminate excessive costs and to allow for rapid delivery. And expensive air valves and bleed devices are eliminated by the WINDJAMMER Blower "add on" design.

So while there are no "customizing" costs, Lamb can still exactly satisfy your air-moving requirements in a wide variety of applications. And at the same time reduce the "cost per hour of operation" in computers, business machines, magnetic tape transports, card readers and sorters, fluidic devices....

In fact, there are very few problems you can't solve with the WINDJAMMER Blower line working for you. Size problems? We've got a tough 5.7-inch model for you. Noise? The WINDJAMMER is one of the quietest blowers made. Weight? The typical five-stage unit is 18 pounds. Life? It'll go for over 20,000 hours.

For complete specifications and performance data on the entire WINDJAMMER Blower line, write us today: Ametek, Inc., Lamb Electric Division, Kent, Ohio 44240.

Teflon bi-pin socket holds miniature bulb

Selectro Corp., Circuit Hardware Div., 225 Hoyt St., Mamaroneck, N.Y. Phone: (914) 698-5600.

Designated as Press-Fit RTS-261, a bi-pin socket accepts micro-miniature bulbs having two 0.017-in.-diameter leads on 0.05-in. centers. Its minor diameter is 0.135 in., and its major diameter is 0.172 in. Fabricated with Teflon, the socket features contacts with gold flash over silver-plated, rolled, beryllium copper. The Teflon body is available in 10 standard EIA colors.

CIRCLE NO. 324
In fact, you could run these dc permanent-magnet generators continuously at 3600 rpm for the next ten years and still have a year and a half of brush life left. They boast a highly linear output and wide speed range making them ideal for velocity or integrating servos, while the low driving torque permits its use as a damping or rate signal in all types of servos. Linearity from 0 to 12000 rpm is better than 1/10 of 1% of voltage output at 3600 rpm. Various models are available with outputs as high as 45v 1000 rpm. The size is miniature. Approximate diameter is 1 3/8". Operates bidirectionally. The rpm's value will not exceed 3% of the dc value at any speed in excess of 100 rpm. Single unit prices from $25.50 with generous quantity discounts. Also available with a meter as a complete Speed Indicating System. ASK FOR CATALOG 1163.

Shield-Cell®

... removable shielded cooling cells that install quickly, economically.

Shield-Cell is available in 3 unique frame designs for quick, low-cost installation. Provides attenuation of up to 100 db. Its metal-to-metal permeated aluminum honeycomb panels can be removed from frames, reducing replacement costs up to 75%. High-reliability design includes METEX electronic weatherstrip RFI gasket. Shield-Cell mounts inside enclosure for extra protection. Write for prices and literature.

Who the Devil is MAC?
## MODULES & SUBASSEMBLIES

### Operational amplifier consumes 8 mW max

![Operational amplifier schematic](image)

**Fairchild Controls, Div. of Fairchild Camera and Instrument Corp., 423 National Ave., Mountain View, Calif. Phone: (415) 962-3833. P&A: $55; stock.**

Featuring low power consumption between 1.8 and 8 mW, model ADO-39 FET-input op amp operates from any supply of ±4.5 to ±20 V with a quiescent current drain of less than 200 µA. Particularly useful in battery-powered equipment, the amplifier has an input impedance of $10^4$ MΩ, a minimum gain of 20,000, and a minimum output of ±1 mA.

**CIRCLE NO. 325**

### Logarithmic amplifier slews at $10^6$ dB/s

**Ithaco Inc., 413 Taughannock Blvd., Ithaca, N.Y. Phone: (607) 272-7640. P&A: $825; 30 days.**

Providing true logarithmic gain control without coupling the control signal into the output, model 316 wideband amplifier is capable of slewing at rates well over one million dB per second. Between 10 Hz and 100 kHz, a control voltage of 0 to 5 V dc adjusts gain at 12 dB/V. The control voltage/gain relationship is logarithmic over a 60-dB range, with ±0.5-dB accuracy. Harmonic distortion is less than 2% at maximum output.

**CIRCLE NO. 326**

### Audio amplifier sustains 15 W rms

**Bendix Semiconductor Div., South St., Holmdel, N.J. Phone: (201) 948-9400. P&A: $9.40; 2 wks.**

Operating from 350-mV input signals, a class-B audio amplifier is capable of sustaining an output of 15 W rms. The hybrid IC, model BHA-0002, achieves useful feedback compensation without external components, while retaining full rated output. Idle currents and crossover characteristics can be trimmed through external terminals. Frequency response is 25 Hz to 20 kHz. Power gain is 60 dB.

**CIRCLE NO. 327**

### Diode function generator customizes gain curves

Providing arbitrary nonlinear shaping of an analog input voltage, a diode function generator is now available as an encapsulated module. Model 4062/45 has slope controls for adjusting each of 11 straight-line segments. No external components are needed to achieve the desired gain curve. Compatible with IC op amps, the unit requires a supply of ±15 V dc.
METALIZED MYLAR CAPACITORS

5 days

M2W SERIES
ANY SIZE, VALUE, VOLTAGE AND TOLERANCE
to your exact specifications... at stock prices

METALIZED MYLAR CAPACITORS
Unique, self-healing units that remain in circuit during voltage surges with little or no loss of electrical properties. Use the M2Ws where size and weight are limiting factors and long life and dependability are required. The units utilize metalized Mylar* Dielectric with film wrap and custom formulated epoxy resin end fill. Available in round and flat styles.

*Du Pont Trademark for Polyester Film

ELECTRONIC DESIGN 23, NOVEMBER 7, 1968
Ferrite Shielded Air Core Yoke C5380. Designed for high speed precision character displays (nanosecond writing speeds). Undesirable magnetic coupling and stray fields eliminated by unique shield design.

Syntronic engineers and manufactures the most extensive line of deflection yokes available . . . and continually develops new designs to satisfy the ever increasing requirements of the display industry. For large production or custom applications get the engineering control and production experience that only SYNTRONIC, the yoke specialists, can provide.

Vector-strut Cages Have Universal Adjustability

- STRENGTH
- HANDSOME APPEARANCE
- QUICK ASSEMBLY
- LOW COST

The Vector-Strut Cage provides an adjustable aluminum frame which through customer test has proven to be more versatile than other competitive units on the market.

- Mountable on 10", 19" or 24" racks.
- Three standard heights - 3", 7 1/4", 9 7/8".
- Prototype quantities shipped from stock. Production quantities in minimum time.
- Vertically slotted side walls and adjustable cross member end brackets allow universal height and depth adjustability for cards and module cases.
- Infinite adjacent positioning capability for module cards and connectors with extruded fastener holding ducts.

"EFP" ALUMINUM MODULE CASES to fit Vector-Strut Cages

- Sixty (60) standard sizes for circuit cards, featuring 1/4" extruded grooves on .150" centers across case width for easy card mounting — no holes required in circuit board.
- Slide out side covers for quick access to cards.
- Front panels with captive thumb screws and rear panels either slotted or closed for user's connector design.

FOR HIGH FREQUENCY Vector Pak plug-in cases provide 90 to 100 DB of shielding with optional side panel gasketing.

Programmable selector switches and trims

Seacor, Inc., 598 Broadway, Norwood, N.J. Phone: (212) 594-9130. Price: from 60¢/station.

Called Switchomat, a programmable, sequential, resistor selector switch consists of one or more pushbutton switches that activate or deactivate its individual 10-turn trimmer pot. Each switch has an associated knob that serves as a fine control, and provides a means for actuating the switch that engages the trimmer circuit.

High-stability, modular, FET operational amplifiers offer maximum drift voltages of 2 to 60 µV/°C. Critical thermocouple junctions between copper input pins and Kovar FET leads are close together so that temperatures remain equal and thermal emfs cancel. Models ADO-19, -26B, -27B, and -29B have a modular construction with discrete FET input stages followed by ICs.
Sample-and-hold card decays at 15 µV/ms

Analogic Co., 296 Newton St., Waltham, Mass. Phone (617) 891-4708. P&A: $249; stock.

Increasing the accuracy and efficiency of conversion applications that require sampled data, a high-speed sample-and-hold module provides a decay rate of 15 µV/ms and a full-scale accuracy of 0.01%. Model AN250-01 settles in 5 µs max with an aperture time (acquisition uncertainty) of less than 50 ns. All control inputs are DTL compatible. Optional modules include a dual configuration for parallel operation.

CIRCLE NO. 331

Booster amplifier supplies ±500 mA

Philbrick/Nexus Research, A Teledyne Co., Allied Drive at Route 128, Dedham, Mass. Phone: (617) 329-1600. Price: $75.

Model 2001 modular amplifier extends the capability of operational amplifier circuits by rapidly and accurately boosting their current to ±500 mA at ±10 V. It has a slewing rate of 10 V/µs and full output response to 80 kHz. Built-in overload protection prevents short-circuit damage even with maximum signal applied.

INFORMATION RETRIEVAL NUMBER 90
Trymetrics' new 4243 Digital Multimeter with AC, DC and OHM readings—auto polarity—full four digit—0.1% ($850) ... a tremendous step backwards. And so are the 4240 DVM ($695) and 4230 DVM ($595).

We started with our Model 4100: stored display—precision .01%, four-digit DVM and its full range of plug-ins for the price of an ordinary 3-digit job—just $740 with the ±9.999v DC head; and eight other plug-ins to choose from. For an encore, the only way to go was down.

Down $195 to $595 for the versatile 4243 Digital Multimeter: DC-AC-OHMS .01%—auto polarity ±999.9mv to ±999.9v. Same 4-digit stored display—no plug-ins. Sorry—unless you don't need plug-ins.

Down again, $155, to $695, for the 4240 DVM. Same high accuracy, same stored display, same ±999.9mv DC to ±999.9v DC 4-digit measurements. But, no AC or OHMS—unless, of course you don’t need AC or OHMS.

Once more, down, to $595 for the Trymetrics 4230 DVM. Still the same precise 4-digit unit with readings ±9.999v DC to ±999.9v DC. Don't buy this one if you need to measure in the low millivolts.

You don’t need true 4-digit readout with .01% accuracy at a 3-digit, .05% price? Sorry—but we can’t keep backtracking forever. May we send you our new catalog that shows ALL our models, our plug-in versatility, our reasons for going backwards?

COMPONENTS

Fiber-optic kit prototypes designs

A kit of fiber-optic components includes glass fiber bundles, image conduits, and fiber-optic tape. It allows the environmental and transmission characteristics of various light guide sizes to be determined, as well as a proposed system to be breadboarded for feasibility study. The kit contains four light guides, a Y-guide for splitting a fiber bundle, and a small flashlight for use as a light source.

CIRCLE NO. 333

Switch contacts have prism shape

Cherry Electrical Products Corp., 1650 Old Deerfield Rd., Highland Park, Ill. Phone: (312) 831-2100. Price: $1.86.

Series E63 switches maintain low contact resistance in low-level switching applications from 5 to 100 mA at 4 to 30 V. The switch contacts, which are made of a gold alloy, are shaped in the form of prisms and welded at right angles to each other. This configuration increases contact pressure and decreases susceptibility to contact closure interference.

CIRCLE NO. 334

Pneumatic amplifier boosts signals 300:1

Aro Corp., 400 Enterprise St., Bryan, Ohio. Phone: (419) 636-4242.

Designed to simplify pneumatic logic functions, an amplifier valve with an adjustable threshold level is capable of providing signal gains as high as 300. The new pneumatic element has a built-in variable orifice that provides a self-generating jet for back-pressure sensing. Sensing pressure ranges from 4 in. of water to 20 psig, output pressure ranges from 25 to 150 psig, and response time is 10 ms.

CIRCLE NO. 335

Photocell scanner detects 50,000/s

Containing light source and photocell in a single housing, model PL-8S4 subminiature high-speed scanner detects small objects at rates above 50,000 per second. It can also accurately pick up code-mark registrations on printed film or paper webs while ignoring unrelated printed marks. Internal lamp bulbs are rated at 40,000 hours, and internal photodiodes have a risetime of only 1.5 µs.

VARIABLE RATE
RASTER GENERATOR
WITH BLANKING AMPLIFIER AND PHOSPHOR PROTECTION
LINEAR DUAL SWEEPS

- Wide Range of Raster Rates
- Sweeps from 20 μsec to 100 msec
- Sweeps Available to Seconds
- 10% to 90% Duty Cycle
- Linearity Better than 0.5%
- Internal, External Trigger or Sync
- ±5 Volt dc Bias
- 5½” High for 19” Rack
- Compatible with CELCO Drivers

The CELCO Dual Ramp Generator provides the display designer with a versatile tool for producing a wide variety of raster or line scan CRT displays. Your answer to a need whenever linear, variable ramp lengths and rates are required — plus the convenience of blanking and phosphor protection.

Immediately available from stock.

Now Available!

New! Lightweight, Tiny (1/64 cu. in.)
Double-Ended Radial Inertia Switch

Calibration range of 5-300 G's with ±10% accuracy.

For sub-miniature printed circuitry, this tiny switch provides sensitivity to forces from any direction. When 2 switches are right-angled, semi-directional response to acceleration is achieved within 1/32 cu. in. Proven performance; this magnetic restraint unit is superior to spring-mass systems.

Model 3R0-498

Size: .175” dia. x 11/16” long
Weight: 1/16 oz. patented
• Operating temperature range: −35° C. to +125° C.
• Complies with Mil Specs E5272.
• Available with either momentary contact or latching.
• 2 AWG No. 26 wire leads, 1½” long.

By George... Captor sure makes small EMC Filters!

Captor subminiature EMC filters are the industry's smallest...25% to 37% more compact than other popular miniatures. Volumes and weights are correspondingly reduced...as light as 4.9 grams for many units. Captor EMC filters maintain high published performance over full temperature range to 125° C. Their performance is equal to or better than the competition's, yet they truthfully cost less! Let Captor bid on your next EMC filter or filter assembly requirement, by George! Write for Catalog F-104 and prices today.

Captor Corporation manufactures miniature filters...communications and security filters...custom-design filters, and other electronic components.

COMPONENTS

Elapsed-time indicator logs up to 10,000 hours

Meeting the requirements of MS-3311 for Weapons Replaceable Assemblies, and of other military system modules, an elapsed-time indicator records actual time in operation up to 1000, 5000, or 10,000 hours. Model 620-PC uses two columns of mercury separated by an electrolyte gap in a capillary tube. Current flow causes the gap to be displaced by electroplating the mercury as a function of time.

CIRCLe NO. 337

Trimmer resistor adjusts in-circuit

Free of moving parts, Fix-Trim metal-film resistor can be user-adjusted before or after installation. Resistance can be varied up to five times the base value with ±0.02% accuracy. Measuring only 0.085 by 0.09 by 0.2 in., type V5 has a rating of 0.05 W at 125°C. Twelve base resistance values cover the range of 1 to 4600 Ω, ±1%. Temperature coefficients to ±25 ppm/°C are available.

CIRCLe NO. 338
A new decode display module provides a cold-cathode tube with a readout that includes decimal-point presentation. Model D-101 accepts 4-line or 8-line BCD codes at typical IC voltage logic levels. It features high speed, reliability and long-life through the use of transistor-transistor-logic monolithic integrated circuits.

CIRCLE NO. 339

Fluidic OR/NOR gates isolate inputs totally

Two OR/NOR fluidic elements feature complete noninteraction between inputs and absolute turn-off when no input signal is applied. Model DN32 is a 2-input unit; model DN33 is 3-input. Fabricated with stainless steel laminates, they feature integral course filters that increase reliability by minimizing contamination vulnerability. Response time is less than 1 ms, and fanout is 3.

CIRCLE NO. 340

Inland torque motor-tachometer generator units: “Tach-Torquers”, use a DC direct-drive torque motor that drives the web transport reel at a precisely controlled, infinitely variable speed with constant tension throughout. The tachometer generator functions as an error sensing transducer producing a DC signal which is used in the electronic loop for immediate response.

A single unit that not only precisely drives the web at any speed in which torque can be varied as dictated by the requirements of the web in any particular station, but also provides immediate rate information with better than 0.1% accuracy.

Torque ratings available from 2.55 oz.-in. to 3,000 lb.-ft.

TORQY SAYS:

If you would like further information on designing-in a “Tach-Torquer” for your continuous web transport drive, just drop a line. No obligation, of course.

INLAND MOTOR CORPORATION
SUBSIDIARY OF KOLLMORGEN

INFORMATION RETRIEVAL NUMBER 97
CAPACITORS

They may look like a conventional foil capacitor, but there the resemblance ceases. Made of a synthetic film with a vaporized metal coating, they have certain highly desirable characteristics.

Silverfilm Capacitors are operable from their rated voltage down to the microvolt range— and they are smaller than capacitors now available for such applications. When subjected to over-potentials they are self healing and have no tendency to short circuit. Unlike conventional metallized film capacitors, Silverfilm insulation resistance is not reduced after capacitor healing.

In short, Silverfilm fills a need for a highly reliable, miniaturized capacitor that will operate satisfactorily over wide voltage and temperature ranges.

- Capacities from .01 to 100 mfd.
- Operating temperatures from -55°C to +125°C
- Standard voltage ratings—microvolts to 600 V—others on request
- AC voltage ratings available to 330 V and 400 cycles

COMPONENTS

Miniature trimmer has 0.25-in. dia

Minature Electronic Components Corp., Sub. of General Time, 600 South St., Holbrook, Mass. Phone: (617) 963-7717.

A metal-film trimmer potentiometer with a 0.25-in. diameter combines high-frequency response, infinite resolution, and low temperature coefficient over a full range of resistance values from 10 Ω to 100 kΩ. The single-turn unit is available in two models, the MF2 without stops and MF2S with stops. It withstands the vibration, shock, and humidity conditions of MIL-STD-202B.

CIRCLE NO. 341

Plastic potentiometer replaces synchro

Betatronix Inc., 35 Doyle Court, E. Northport, N. Y. Phone: (516) 368-3170. P&A: from $35; stock to 8 wks.

Replacing the control transformer used in conventional synchro systems, a plastic potentiometer has a resistivity that varies as a trigonometric function of its wiper displacement. It is available in either standard potentiometer or synchro housing configurations with diameters ranging from 0.5 to 5 in.

CIRCLE NO. 342

Ceramic capacitors filter and bypass

U.S. Capacitor Corp., 2151 N. Lincoln St., Burbank, Calif. Phone: (213) 843-4222. P&A: 77¢ to $8.43; 3 wks.

Designed to replace mica, glass or porcelain capacitors, miniature ceramic chips can be used in filtering, bypass and coupling applications. These stable ceramic capacitors are available in three types: C13 series—tubular with axial leads, with a capacitance range from 0.5 pF to 0.2 µF; C17 series—rectangular with radial leads, 5 pF to 0.22 µF, and C18 series—rectangular with axial leads, 5 pF to 0.011 µF. Working voltage ratings are 50, 100 and 200 Vdcw.

CIRCLE NO. 343

Chip capacitors withstand 4000 V

Monolithic Dielectrics Inc., P.O. Box 637, Burbank, Calif. Phone: (213) 349-4465.

Currently used in photomultiplier circuits for image-intensifier optics, a 4000-V ceramic chip capacitor features a leakage current of as little as 1 nA. Dissipation factor is less than 1% at 1 kHz and insulation resistance is 100 GΩ at 25°C. Rated life is 1000 hours at 125°C. These capacitors meet the requirements of applicable sections of MIL-C-11015 and -39014.

CIRCLE NO. 344
You may have seen them before. You’ll see these ads often this year in national media space contributed to the cause of traffic safety.

They’re trying to keep your employees alive and healthy. By encouraging them to use safety belts, both in their private driving and on the job for you.

But they can’t succeed all by themselves. And that’s where you come in.

You can encourage every one of your employees to use safety belts regularly.

Warn about the lethal danger of making excuses. Remind them that 7000 people died last year because they weren’t wearing safety belts when they ran into trouble.

If you do your part, you’ll be helping your employees stay alive and well. And on the job for you.

If you don’t . . . what’s your excuse?
Electronic Design

here's how industrial advertising

1. SELF-SERVICE BUYING—A MAJOR POTENTIAL

Now there is a bold new approach to marketing.
We call it DATA-SELL. Its goal is to telescope the selling process so that your advertisements will bring in more orders... faster. If you are content merely to arouse interest or "communicate" with your prospects, you are missing a big potential in this industry.

Already, advanced marketers are leapfrogging closer to the sale. Instead of inquiries, their ads often bring in immediate results. The technique works... it's being used... it's applicable to almost any advertiser, large or small... to almost any product.

DATA-SELL begins by taking a new look at the buyer and his needs. In the electronic OEM, everybody knows it's the design engineer or engineering manager who specifies and buys. But how does he do it?

He sees your ad...
He inquires about your product...
He sends you product information...
He compares...
He decides...
Every step takes time, every step costs money.

DATA-SELL takes advantage of the tremendous self-service buying potential in this industry. You simply give the engineer the data he needs... right away... in your ad, impossible? Read on to see how it is being done—right now—to build sales and profits.

2. SPECIFICATION AND PURCHASE MADE WITHOUT PARTICIPATION BY SALESMEN

Self-service buying underlies the basic marketing philosophy of DATA-SELL. Research data is now available to prove that electronic design engineers and engineering managers often buy without seeing a salesman. It's obvious that this must happen because few companies' salesmen could possibly touch all the bases in this industry—keep up with all the orders. But, now there's proof!

MORE PROOF!
In June, 1968, we reported positive sales results for Electronic Design's DATA-SELL technique as surveyed by National Semiconductor Corp., and Electro Scientific Industries. Now here's more proof.

BALLANTINE LABORATORIES FOUND OUT that 19.7% of Electronic Design's primary audience had specified electronic measuring instruments within five months of the appearance, in Electronic Design, of a Ballantine ten-page DATA-SELL insert. Of the sales explored, 61.4% were made without a salesman's call, including all of Ballantine's sales reflected by survey respondents.

SIMPSON ELECTRIC COMPANY FOUND OUT that 97% of the 1,000 Electronic Design subscribers surveyed had some degree of familiarity with Simpson's product line. (Simpson's 48-page DATA-SELL unit appeared in Electronic Design, May 8, 1968.) Of the 506 respondents, 61.1% recalled seeing Simpson's advertising. Of the 103 sales explored in the survey, 89.3% had been made without even talking to a Simpson salesman!

UNION CARBIDE ELECTRONICS FOUND OUT that 53.4% of Electronic Design's primary audience specifies FETS. Of the 25.5% who specified or requisitioned FETS within 3 months preceding survey date, 43.4% did so without a salesman's call!

A FOLLOW-UP STUDY OF ALL INQUIRIES TO THE FEBRUARY 1, 1968 ISSUE OF ELECTRONIC DESIGN showed that:
1. Although 87.9% of Electronic Design's readers received the information they requested through Information Retrieval channels, only 7.3% were contacted by a salesman.
2. 83% of the specifications of advertised products were made without a salesman's call.

3. TELL THE ENGINEER ALL THAT HE NEEDS TO KNOW

DATA-SELL is basically a "tell-all" technique. You must anticipate the technical data most of your engineer-customers will need for most applications. The object is to avoid drawn out correspondence... eliminate questions... anticipate needs... so that engineers can even make their first communication an order instead of an inquiry. Or, if further contact is necessary, it is speeded up, simplified, easier to process.

Here are some basic examples of the kinds of information engineers often require in order to specify. (You will have to refine this list, of course, to suit your own products.)

- Operating ranges
- Key performance parameters
- Accuracy ratings
- Reliability test results
- Sensitivity
- Interconnections
- Power requirements
- Options
- Packaging
- Delivery time
- Size
- Weight
- Cube
- Cost
- MIL approval

The tell-all technique of DATA-SELL gives the engineer all of the information he needs to make self-service buying decisions—right now.

4. DATA-SELL WILL ALTER BENCHMARK STUDIES PROVE DATA-SELL TECHNIQUE EFFECTIVE

To measure the impact of a series of three DATA-SELL inserts run in Electronic Design by Texas Instruments, Semiconductor Components Division, "Before" and "After" studies were conducted. The "Before" study questionnaire was mailed Aug. 24, 1967 to an n/a sample of 1,000 drawn from Electronic Design's domestic circ. list; the "After" questionnaire was mailed to a similar unduplicated sample on 3/29/68, after the appearance of the last insert. Survey results are highlighted at right. The complete survey is available on request.
can sell your products RIGHT NOW!

YOUR CAMPAIGN STRATEGY

5 HOW TO OBTAIN FUNDS FOR YOUR PROGRAM

If your budget has been set without an understanding of how DATA-SELL can revolutionize your advertising program, here are several ways to obtain the necessary funds. (Ideally, DATA-SELL should be planned and funded as a separate part of your marketing program.)

- SET NEW GOALS—Make realistic projections combining your own track record with the DATA-SELL experience of others. Set new goals and budget accordingly.

- BORROW FROM SALES—DATA-SELL acts like a salesman. It can even be considered as an extra salesman. Talk to your sales manager.

- BORROW FROM DIRECT MAIL—DATA-SELL really is direct mail—only it costs less, reaches more prospects and gets higher readership.

- CONCENTRATE TO SELL—Eliminate marginal publications. There's much more potential business to be found by the DATA-SELL technique in your leading magazine than you can possibly obtain by adding random circulation in lesser books.

6 SELECT THE MOST EFFECTIVE, MOST EFFICIENT PUBLICATION . . . IN THE ELECTRONIC O.E.M. IT'S Electronic Design

CIRCULATION MOVES UP TO 69,000 IN NOVEMBER

100% design engineers and engineering managers—more than 69,000 men responsible for the specification of electronic products. Pass-along copies swell Electronic Design's total audience to more than 213,000! (Most of the 7,000 added coverage is in the major companies where IC and LSI activity is highest.)

READERSHIP

Electronic Design has won more independent readership studies than all other electronic publications combined!

More than 1,200,000 last year—far more than any other publication in this field.

LOW 4-COLOR RATES

A recent survey shows that 4-color advertisements attract twice as many readers as black and white or two-color ads. These low rates mean that DATA-SELL ads in 4-color can bring 100% increase in readership for only 1/2 additional cost!

MULTI-PAGE DISCOUNT RATES

To encourage DATA-SELL multi-page advertising, special Electronic Design discount rates apply. Multi-page ads earn discounts ranging from 10% to 75% depending on frequency.

BUDGET YOUR DATA-SELL INSERTS NOW

Here's how to start: (1) Proceed with your regular campaign. (2) Pick those of your products that engineers can buy directly when complete information is furnished. (3) Budget and schedule enough multi-page DATA-SELL inserts to do the job. (4) Place your order as soon as possible—only a limited number of multi-page DATA-SELL units can be accepted for any one issue.

SEND FOR CASE HISTORIES OF SUCCESSFUL DATA-SELL CAMPAIGNS

Ask your local Electronic Design representative for more information about DATA-SELL—or contact Ed Clancy, Advertising Services Manager at (212) PL 1-5530.
Design Aids

Laser data chart

A 22 by 24-in. data compilation chart folds for insertion into a notebook. Included are formulas for wavelength and energy conversion, output wavelength and fluorescent lifetime of various laser systems, indices of refraction, angular to linear conversion, physical constants, recommended unit prefixes; beam-shaping formulas, Xenon flashlamp approximations, and laser radar range formulas. The chart also lists designation, source and wavelength of spectral lines used in spectrometric measurements; optical transmission data; energy bank formulas; and networking formulas. Laser Nucleonics Inc.

CIRCLE NO. 345

Molded case selector

Fiber glass cases can be easily specified with the aid of a special slide-rule selector. To determine the proper case for a specific application, one simply sets desired dimensions into the five windows provided, and the slide rule does the rest. Descriptive literature on a line of military and commercial cases is included with the rule. Skydyne, Inc.

CIRCLE NO. 347

Plating guide

Listing military and industrial specifications for plating with precious metals, base metals and alloys, a comprehensive handbook also discusses end-uses and gives an analysis of required metallurgical properties. Easy to read tabular charts permit the reader to match applicable specifications, end-use requirements, and recommended plating formulations. LeaRonal, Inc.

CIRCLE NO. 348

Conversion formulas

Included as a bonus with a 24-page meter catalog are two pages of useful engineering data. A glossary lists and defines terms useful in specifying panel meters. A second full page is devoted to conversion factors, formulas, and tables. Included are formulas for ac and dc circuits, sinusoidal voltages and currents, reactances, impedances, conductance, susceptance and admittance. A decibel table correlates dB values with power ratio and voltage or current ratio. Weston Instruments, Inc.

Now, METAL GLAZE resistors for MIL-R-10509

IRC's newest Metal Glaze resistors offer the most economical approach to MIL-R-10509 requirements. They have precision performance, plus the added benefits of thick-film stability and reliability.

These resistors feature IRC's latest generation of Metal Glaze resistance material. This improved thick-film element provides the electrical stability and mechanical ruggedness that tin oxide types can't achieve. And, their tough molded bodies resist solvents and the pounding of automated inserting equipment.

Metal Glaze resistors have withstood over 15 million unit hours of testing. In addition to MIL-R-10509, they also meet or exceed MIL-R-22684 and MIL-R-39017. For complete data and prices see your IRC Qualified Industrial Distributor. Or, write IRC, 401 North Broad Street, Philadelphia, Pa. 19108.

Digital recording

Recently published, a technical note evaluates cost factors involved in digital recording. Various techniques of incremental and continuous IBM-compatible recording are examined and compared. A discussion of non-IBM-compatible cassette recorders is also included. Cipher Data Products, Inc.

CIRCLE NO. 351

Computer glossary

An 8-page glossary lists and defines terms for tape and transmission formats. Included are many of the most common terms used in magnetic tape data storage technology. Computer Products Div. of Tally Corp.

CIRCLE NO. 352

PC production data

A fully diagrammed technical data sheet covers the step-by-step production of plated-through holes in PC-board production. All eight steps are illustrated and described. London Chemical Co., Inc.

CIRCLE NO. 353

Photocell design manual

A 16-page designer's guide to photocell theory, design, and properties from the application viewpoint. Included in the manual are sections on photocell theory, spectral and color temperature-response speed, light history effects, and maximum voltage. Clairex Corp.

CIRCLE NO. 354

Schottky-barrier diodes

Performance characteristics of silicon microwave Schottky-barrier diodes are described in an applications report. The report briefly describes metal-semiconductor theory as applied to the Schottky-barrier junction, and the importance of reducing losses of junction parasitics. The remainder of the paper describes characteristics of Schottky-barrier diodes as mixers and detectors at S- and X-bands. Microelectronics Division, Philco-Ford.

CIRCLE NO. 355

Application note catalog

Motorola Semiconductor Products Inc. has published an application note catalog listing the number, title, and a brief summary of more than 130 available papers describing circuit and system application designs. Many of the notes listed in this 11-page catalog are reprints of actual articles prepared by Motorola applications engineers and published in leading electronics magazines. Motorola Semiconductor Products Inc.

CIRCLE NO. 356

Step recovery diodes

A 32-page application note describes the theory and practice of two step recovery diodes: harmonic frequency multiplication and comb spectrum generation. The note summarizes important design criteria concerning multiplier noise, bandwidth, stability, and deficiency, and tells how to build multipliers that are stable over broad temperature ranges and under all phases of a short-circuit termination. Hewlett-Packard.

CIRCLE NO. 357

Digital logic

A new 200-page workbook contains a complete course in digital logic. Designed for use with a digital logic teaching device, the work-book contains 46 experiments and over 160 illustrations and diagrams. Digital Equipment Corp.

CIRCLE NO. 358
Centralab's Little Giant zeners thrive in tight spots. Their performance and competitive pricing have opened new product miniaturization possibilities in entertainment, industrial and high reliability military and aerospace applications.

Our 400 mW regulator has a zener voltage breakdown of 6.8 through 200 volts; the 1 watt from 6.8 through 200 volts; and the 1.5 watt from 6.2 through 200 volts. So the Little Giants do a big job in cramped quarters. What else? They're tough. So tough that gruelling tests of acceleration, mechanical and thermal shock, vibration, lead and body strength, temperature, humidity, salt spray and altitude leave them unscathed. Centralab's Little Giant zeners.

Real crowd pleasers.

FOR MORE INFORMATION ON DIODES, SOLAR CELLS AND READOUT DEVICES, WRITE CENTRALAB TODAY. THESE CENTRALAB PRODUCTS ARE MARKETED DIRECT TO MANUFACTURERS AND THROUGH CENTRALAB SEMICONDUCTOR DISTRIBUTORS; INTERNATIONALLY THROUGH GLOBE-UNION INC. — INTERNATIONAL DIVISION.
New Literature

Allied industrial catalog

Allied's 1969 catalog of electronic equipment for industry and government is now available. This 600-page book, the largest issued by an electronics supply house, lists over 50,000 stock items from over 500 manufacturers for research and development, production, communications, education, controls and entertainment. Allied Electronics Corp.

CIRCLE NO. 359

Panel-light hardware

Data, illustrations and military type designations for lens-cap and base assemblies are provided by a 24-page illustrated brochure. The catalog is complete with an index and a replacement cross-reference chart that enables the user to quickly find the desired base and mating lens-cap assemblies. Dialight Corp.

CIRCLE NO. 360

Thermoplastic resins

Newly revised, this 12-page publication describes electrical/electronic uses of thermoplastic resins, including their use in radio and TV components, business machines, control equipment and switchgear, military components and appliances. General Electric Co., Polymer Products Operation.

CIRCLE NO. 361

Adhesive selector chart

An up-dated reference chart suitable for notebook or wall mounting lists the important properties of a line of adhesives. The chart is conveniently arranged to expedite the selection of the proper adhesive. Products with similar properties, such as liquid epoxies, epoxy pastes, and electrically conductive adhesives, are grouped together. For each group the important mechanical, thermal and electrical properties are described. Emerson & Cuming, Inc.

CIRCLE NO. 362

Silicon photocells

Case history studies describe the physical and electrical flexibility of silicon photovoltaic cells, and show how they provide a degree of electro-optical design freedom that can only be approached by a multiplicity of discrete devices. Sensor Technology, Inc.

CIRCLE NO. 364

Crystal filters

A four-page bulletin describes a line of monolithic crystal filters and their components, and compares their applications and advantages with conventional crystal bandpass filters. Included are specifications for the complete line of filters. Damon Engineering, Inc., Electronics Div.

CIRCLE NO. 363

Fasteners

A 20-page standards catalog provides basic information on a broad line of self-drilling fasteners, lock washers, spring washers, thread-cutting screws, locking terminals and other cost-saving fasteners. This condensed reference book contains basic catalog information, illustrations, and a bibliography. Shakeproof, Div. Illinois Tool Works, Inc.

CIRCLE NO. 365
ZELTEX Model 830, the FIRST fet 'op amp' in a dual-in-line package . . .

try that on for size

The big news in miniature amplifiers is the ZELTEX 830—the industry’s first in a DIL package—and the first in a new ZELTEX family of DIL analog functions. What’s more, the 830 is fully compensated and short circuit-proof. Performance? The spec’s tell the story. • Voltage gain is 300,000 • 20µV/°C drift • input bias current of 15 pA • 6V/µsec slew rate • 10 volt common mode voltage, and • output of 10 volts at 5 mA. Available from stock, too. Size up the 830 now. Write for complete data and prices. • 1000 Chalomar Rd., Concord, Ca. 94520. Phone (415) 686-6660.
They said it couldn’t be done!

**a CONTROL METER RELAY with 50% savings and high performance**

WELL, THEY WERE WRONG! After a year of customer use in the field, our customers report that our units are consistently providing high accuracy and high reliability — and they must be right because they are re-ordering and pocketing cost savings of up to 50%. Why not join our increasing list of satisfied customers now?

Beede’s Non-Contacting Control Meter Relay was initially designed to offer a wide choice of design options for the greatest application versatility. For instance:-

- 8 or more choices of power supply
- 4 choices of fail-safe configuration
- 10 or more choices of output mode
- 9 choices of alarm lights and reset switches
- Many special features such as tamper-proof units, fixed set point, etc.
- Pyrometers and resistance thermometers

NEW LITERATURE

**Hybrid microcircuits**

The manufacturing process of a hybrid microcircuit, from the engineering drawing to the finished package, is outlined in a newly revised brochure entitled, “The Making of a Hybrid.” The eight-page booklet pictorially describes the step-by-step procedures involved in the manufacturing process. A typical circuit is taken through the production cycle to illustrate how advanced techniques are employed to assure an accurate, highly reliable microcircuit. WEMS, Inc.

CIRCLE NO. 366

**High-speed TTL ICs**

Seventeen high-speed TTL integrated circuits with a typical gate propagation delay time of 13 ns are now in production. Complete details including parameter measurement data are given in a 48-page engineering bulletin that is available upon request. Sprague Electric Co.

CIRCLE NO. 367

**Magnetic record heads**

A 20-page, two-color catalog contains mechanical and electrical specifications, and typical response curves for a line of recording heads. These heads meet most requirements for full-, half-, quarter-, and eight-track units. Michigan Magnetics.

CIRCLE NO. 368

**Instrument journal**

The latest issue of the Hewlett-Packard Journal discusses signal generation and spectral analysis. Published monthly, the journal is offered at no charge to engineers and technical personnel. Hewlett-Packard.

CIRCLE NO. 369

**Solid-state relays**

Catalog 750 describes the features of a line of solid-state relays, such as inherent contact isolation and universal operating voltage range. Application data on transient protection, surge current handling, load/current temperature derating, and turn-on sequence are presented graphically. Ohmite Mfg. Co.

CIRCLE NO. 370

**Rf techniques**

A 16-page catalog details many advances in rf techniques, and offers general as well as detailed specifications and descriptions for a wide range of products. These include amplifiers, attenuators, converters, filters, frequency multipliers, multicoplers and multiplexers. Applied Research Inc.

CIRCLE NO. 371

**Semiconductor catalog**

A 28-page catalog lists electrical specifications and ratings for the following semiconductor products: regulators, mil spec items, general purpose diodes, rectifiers, tunnel diodes, temperature-compensated reference devices, silicon controlled rectifiers, TD/SCR switching system tunnel-diode triggers, photovoltaic components and devices, and readouts. Dimensional drawings are included for all case types. Centralab, the Electronics Division of Globe-Union Inc.

NOW! 2 SUPERIOR DRY FILM LUBRICANTS
tailored for your specific industrial needs!

FEL-PRO C-300
Air-dries and cures in 1 hour while offering -65°F. to 1200°F. protection

FEL-PRO C-200
Bakes on to give outstanding performance throughout -65°F. to 2400°F. range

High-temperature and low-speed lubricating problems? Forget oils, greases and other short-life lubricants! These non-corrosive FEL-PRO products brush or spray on quickly, then dry to a solid yet slick film that fights friction, wear, abrasion, fretting. Either type provides positive, long-life protection for all metals and their derivative alloys, ideally suited for heavy-load, low-speed applications that require excellent adhesion and extreme pressure resistance. Try C-300 or C-200 once... and you'll never settle for less!

Write on your letterhead for free sample, technical data, and price information. Please state which product desired and intended application.

FEL-PRO FEL-PRO, INC., A Division of Felt Products Mfg. Co.
7450 N. McCormick Blvd., Dept. ED, Skokie, Ill. 60076

1001 uses for STEPPER MOTORS

Because their output is in discrete increments, Cedar stepper motors have many advantages over conventional motors for precise positioning applications. They are bi-directional and have high torque output. They can be run at high stepping rates or as slow as you wish. Because shaft rotation is incremental, damping is not required.

Some of the applications for which stepper motors have been used are: replace motor-tachometers in servo systems, control missile ailerons, shutter control on high-speed cameras, open loop positioner in checkout systems, high-speed counter in such applications as rapid firing weapons, replace ultra low-speed dc motors, incremental tape handlers, and digital-to-analog and analog-to-digital conversion equipment.

The uses for stepper motors are as unlimited as your imagination. New applications are constantly being discovered. What new use will you next make of stepper motors? Let us know about your ideas; we'll be happy to work with you.

Cedar Stepper Motors are available in sizes 5, 8, 11 and 15 in both permanent magnet and variable reluctance types, and with a wide variety of stepping angles. All meet the full requirements of MIL-E-5272. For free booklets on stepper motor application ideas, write or call:

INFORMATION RETRIEVAL NUMBER 107
The new Compact "M" Series Power Packs offer you:

- Rated output voltages from 1000 to 75,000 DC
- Rated output currents of 1.5, 5, and 10 milliamperes
- Input voltages of 118, 220, 230, and 240 volts AC
- Variable output from 0 to rated voltage
- Input frequency range 50 to 500 CPS
- Output ripple 1% RMS at rated voltage
- Hermetically sealed construction

Why pay more, and settle for less... PC's new compact power packs give more quality, more versatility, more dependability, plus smaller size, and best of all, most sizes are available in stock to meet your immediate needs.

Write for complete information and new catalog today!

Data transmission

Applications of high-speed data transmission are discussed in an 18-page booklet that describes three such systems. Model 2056 is an asynchronous channel in which two- or three-state data streams may be transmitted. Model 3227 is a coherent channel in which two-state data streams may be transmitted along with and in synchronism with 50% clock pulses. Model 4000 is a synchronous channel in which the clock information is taken from the data set at both ends. RFL Industries, Inc.

Photodiode notes

Application notes on SGD-100 and SGD-444 photodiodes describe the characteristics and operation of these high-speed, high-sensitivity devices. Both silicon photodiodes offer a planar-diffused, guard-ring construction. They feature a unique combination of high quantum efficiency (70%), wide spectral range (0.35 to 1.13 μm), nanosecond speed or response, low noise levels and high linearity. EG&G, Inc.

Potentiometer brochure

An eight-page adjustment potentiometer brochure features nomenclature, dimensions, specifications, price listings, and detailed photos. Specifications given include those for resistance tolerance, power rating, maximum temperature, adjustment turns, standard resistance and humidity. Bourns, Inc.

Laser trimming

A four-page data sheet describes the factors involved in mass producing precision-trimmed cermet resistors with an automatic laser trimming system. Laser trimming of these high-temperature resistors is fast and precise. It reduces the need for stringent control during the manufacturing process and produces tolerated resistors of exceptional quality. Spacerays, Inc.

Measuring equipment

A 35-page catalog lists and pictures all major elements of a line of electronic measuring instruments. Brief descriptions are provided with each entry, and specifications are listed for major items. B & K Instruments, Inc.

IC digital counters

A comprehensive review of characteristics, applications, detailed specifications and operation information of a series of IC digital counter/timer/frequency meters and companion plug-ins appears in this 24-page brochure. Bulletin #74-1702 covers all modes of application provided by these instruments. Monsanto Electronics Technical Center.
New Arvin 1 MHz TCXO off-the-shelf for only $150 each

We can manufacture and deliver in quantity TCXO’s to these specifications:
- Frequency ... 1 MHz
- Stability ... 5 PP 10' from -40°C to +75°C
- Supply Voltage ... 12V ±1VDC
- Output ... 750mv ± 10% into 1000 ohms
- Packaging ... 1.125" high x 2.00" dia.
- Specs ... designed to meet MIL Specs
- Price ... $150 each. Less in quantity
- Delivery ... immediate.

Next time you need a proven TCXO capability, call (317) 743-9639.

ARVIN FREQUENCY DEVICES
ELECTRONIC SYSTEMS DIV., ARVIN INDUSTRIES, INC.
2505 N. Salisbury, West Lafayette, Indiana 47906

1.7 to 11 pf machined plate capacitor for PC mounting is only .310” in diameter

This new, sub-miniature Type “T” air dielectric trimmer capacitor from E. F. Johnson fits the limited space requirements of modern design. It is designed for VHF and UHF applications where small size (.310” diameter), high Q (greater than 1500 at 1 MHz), low TC and low cost are important considerations.

The Type “T” mounts interchangeably with widely used 3/16” printed-circuit-type ceramic disc trimmers in two .050” diameter holes on .300” centers.

Nominal capacity is 1.7 pf minimum, 11.0 pf maximum. Peak voltage breakdown is 250 VDC. End frame is 95% alumina, grade L624 or better, DC200 treated. Metal parts are silver plated and Iridited.

Johnson machined plate construction provides exceptional stability, including minimum drift over extremes of temperature and humidity.

MAY WE TELL YOU MORE? Write for detailed specs and prices on Type “T” capacitors. And ask for Components Catalog 701 covering the entire E. F. Johnson component line.
Electronic Design's function is:

- To aid progress in the electronics manufacturing industry by promoting good design.
- To give the electronic design engineer concepts and ideas that make his job easier and more productive.
- To provide a central source of timely electronics information.
- To promote two-way communication between manufacturer and engineer.

Want a subscription? ELECTRONIC DESIGN is sent free to qualified engineers and engineering managers doing design work, supervising design or setting standards in the United States and Western Europe. For a free subscription, use the postfree application form inside the back cover. If none is included, write to us direct for an application form.

If you do not qualify, you may take out a paid subscription for $25 a year in the U.S.A., $35 a year elsewhere. Single copies are $1.50 each.

If you change your address, send us an old mailing label and your new address; there is generally a prepaid postcard for this inside the back cover. You will have to requalify to continue receiving ELECTRONIC DESIGN free.

The accuracy policy of ELECTRONIC DESIGN is:

- To make reasonable efforts to ensure the accuracy of editorial matter.
- To publish prompt corrections whenever inaccuracies are brought to our attention. Corrections appear at the end of the Letters column.
- To refuse any advertisement deemed to be misleading or fraudulent.

Microfilm copies are available of complete volumes of ELECTRONIC DESIGN at $19.00 per volume, beginning with Volume 9, 1961. Work is now in process to complete the microfilm edition of Volumes 1-8. Reprints of individual articles may be obtained for $2.00 each, prepaid ($0.50 for each additional copy of the same article) no matter how long the article. For further details and to place orders, contact the Customer Services Department, University Microfilms, 300 North Zeeb Road, Ann Arbor, Michigan 48106; telephone (313) 761-4700.

Want to contact us? If you have any comments or wish to submit a manuscript or article outline, address your correspondence to:

Electronic Design 23, November 7, 1968
So when you're building printed circuits, you save time and money in both layout and construction. And the new HP 10534C Double Balanced Mixer has the same high performance, versatility and ruggedness as Hewlett-Packard's other models, yet is only 0.4" wide, 0.35" deep and 0.43" high when seated.

The 10534C mixer has a range of dc to 150 MHz on one port, 50 kHz to 150 MHz on the other two. Conversion loss is 6.5 dB over the HF band, 8 dB over the entire range. Typical balance is better than 15 to 35 dB, depending on frequency and test connections.

These small, high-performance mixers are available immediately at $60 each, or at liberal quantity discounts.

HP offers a selection of five mixers with four connector options, low 1/f noise, complete testing with parameters specified in detail, and guaranteed performance over a wide environmental range. For detailed specifications, call your HP field engineer, or write Hewlett-Packard, Palo Alto, California 94304; Europe: 54 Route des Acacias, Geneva.

These new sub-mini mixers

fit the same hole pattern as your flat-pack IC's

and use the same board area as your TO-5 cans.
New... RCA-2N5497 Family Extends Your Current Choice in TO-66 Plastic Power Transistors to 3.5 A

Ruggedness, versatile configuration, high power density—these are key features of RCA's recently announced 2N5490 through 2N5497 n-p-n transistors in the highly reliable "plastic TO-66 package." Intended for a wide variety of medium-power switching and amplifier applications, this new family augments previously announced types 2N5293 through 2N5298, and extends RCA's total current handling capability with good gain over the range from 0.5 to 3.5 A... power dissipation from 36 to 50 watts.

These new power devices provide top performance. RCA mounts the silicon chip directly onto a solid copper base for better current handling, improved thermal resistance, and dissipation capabilities. Also, all units provide designs with freedom from second breakdown—the inherent advantage of RCA hometaxial-base technology.

Check the chart. For more information, see your RCA Representative or your RCA Distributor. For technical data on specific types, write: RCA Electronic Components, Commercial Engineering, Section I-G-11-1, Harrison, N. J. 07029.
