IBM 5110
APL Introduction
IBM 5110
APL Introduction
Preface

This manual discusses the mechanics of using APL with the IBM 5110 Computer. It is intended to provide the users of this system with information necessary to operate the system using the APL language.

CHAPTER 1. INTRODUCING THE IBM 5110

Chapter 1. Introducing the IBM 5110

About this Manual

About the APL Language

About the System

Alphameric Keys

Numeric Keys

Operating Keys

APL System Command Keywords

Arithmetic Function Keys

Getting Started

Entering and Displaying Data

Correcting Keying Errors

Replacing a Character

Deleting a Character

Inserting a Character

Entering Lowercase Alphabetic Characters

CHAPTER 2. INTRODUCING THE APL LANGUAGE

Types of Functions in APL

Addition, Subtraction, Multiplication, and Division

Another Arithmetic Function—Raising a Number to a Power

Finding the Root of a Number

Storing Data in the 5110 for Later Use

Performing Several Functions in the Same Expression

Specifying the Order of Execution—Using Parentheses

Using Strings of Numbers and Tables

Using APL with Strings of Numbers (Vectors)

Using APL with Tables of Numbers (Matrices)

Referring Only to Certain Numbers in a String or Table of Numbers (Indexing)

You Are Not Limited to Using Only Numbers

CHAPTER 3. APL FUNCTIONS THAT REQUIRE ONE ARGUMENT

How Many Arguments Are Required by an APL Built-In Function?

APL Function Symbols That Are a Combination of Two Characters

Determining the Whole Numbers Nearest a Fraction

Rounding to the Nearest Whole Number

Sorting a Vector in Ascending or Descending Sequence

Generating a Random Number

Generating Consecutive Numbers

Generating an Empty Vector

Finding the Shape of an Existing Variable

CHAPTER 4. APL FUNCTIONS THAT REQUIRE TWO ARGUMENTS

Relational Functions

Why Two Numbers Identical in Appearance Are Not Always Equal

An Example Using a Relational Function

Logical Functions

And

Or

Finding the Larger of Two Numbers

Finding the Smaller of Two Numbers

Finding the Index of a Value in a Vector

Generating a Random Sequence of Numbers

Selecting Certain Elements (Compressing) From a Vector or Matrix

Expanding a Vector or Matrix

Joining Two Items Together

Building a Vector of Results Using Catenation

Finding the Logarithm of a Number

CHAPTER 5. APPLYING THE SAME FUNCTION TO ALL THE ELEMENTS OF A VECTOR COLLECTIVELY (REDUCTION)

Plus Reduction

Using Plus Reduction to Find the Average

Using Plus Reduction to Sum the Products of Two Vectors

Minus Reduction (Alternating Sum)

Maximum Reduction: Finding the Largest Value in a Vector

Minimum Reduction: Finding the Smallest Value in a Vector

Or Reduction: Checking for a Specific Value in a Vector

And Reduction: Checking for All Values in Two Vectors Being Equal

CHAPTER 6. USING THE BUILT-IN FUNCTIONS

Now Let's Look at the Things You Can Do
ABOUT THIS MANUAL

This manual will show you how to operate the IBM 5110 using the APL language. If you are not familiar with the APL language, you should do the suggested keying operations or examples on your 5110 while reading the manual from cover to cover. If you are familiar with the APL language, you should read Chapters 1 and 2 to learn how to operate the 5110; however, you may then want to skip to Chapter 7. Not all of the features or functions of the APL language are covered in this manual. For more information about the 5110 or the APL language, see the IBM 5110 APL User's Guide, SA21-9302, or the IBM 5110 APL Reference Manual, SA21-9303.

This manual was written with the assumption that the 5110 has been set up and checked out. If the 5110 has not been set up, use the setup procedure in the IBM 5110 Setup Procedure, SA21-9318, before continuing to read this manual.

ABOUT THE APL LANGUAGE

APL has many built-in functions that allow you to effectively solve your problems. However, if you need a special function to solve a problem, APL also allows you to define your own functions. The functions you define are similar to programs written in other computer languages.

APL is a good language to experiment with; nothing you do from the keyboard can damage the 5110, and the more you experiment, the more you will learn about APL.

ABOUT THE SYSTEM

The IBM 5110 Model 1 (Figure 1) is a computer designed to help you solve problems. The IBM 5110 Model 2 differs from the Model 1 in that the Model 2 does not have a built-in tape unit. The display screen and indicator lights communicate information to you, and the keyboard and switches allow you to control the operations the system will perform.

Before you begin to use the 5110, you should become familiar with the keys and control panel. The control panel switches will be discussed later. Following is a brief description of the keys (Figure 2); how you use the keys will be discussed later.
Alphameric Keys

The alpha keys are similar to those on a standard typewriter, except that there are no lowercase characters. In standard APL character mode, the alpha characters are all uppercase, even though they are in the lowercase position on the keys. Thus, you do not use the shift key for alpha characters.

If you want to enter an upper shift character, you must hold down the shift key and then press the key to enter the character, just as you would to type an uppercase character on an ordinary typewriter.

You can also enter lowercase alphabetic characters from the keyboard. How you enter lowercase alphabetic characters is discussed later in this chapter.

Numeric Keys

Either the top row of alphameric keys or the special calculator arrangement of numeric keys can be used to enter numbers.

Operating Keys

The black key labeled EXECUTE, the dark gray keys with the legend names CMD, ATTN, and HOLD, and the dark gray keys with the arrows are all special operating keys. The keys with the arrows and the spacebar, which is used to enter blank characters, automatically repeat the operation they perform when held down.
Figure 1. The 5110 Computer
APL System Command Keywords

The words that are above the top row of numeric keys are system command keywords, which you can enter by holding down the CMD key and then pressing the key below the desired keyword. For example, to enter LOAD, hold down CMD and press the 1 key. The system commands and their uses are discussed later, in Chapter 9.

Also, notice the special character combinations engraved on the front of the alphabetic keys. If you have a combined APL/BASIC machine, there is also a BASIC statement keyword engraved above the special character combination on the front of the key. You can enter the special character combination by holding down the CMD key and then pressing the appropriate key. You will see how these special character combinations are used as you become familiar with the APL language.

Arithmetic Function Keys

The four keys to the right of the calculator arrangement of numeric keys are the arithmetic function keys. These keys are used to perform division, multiplication, subtraction, and addition. There are also keys on the alphameric keyboard that perform these functions. Notice that the ÷ and x symbols are used for division and multiplication.
GETTING STARTED

Make sure the switches on your IBM 5110 are set as follows:

<table>
<thead>
<tr>
<th>Switch</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>L32 64 R32 (5110 only)</td>
<td>64</td>
</tr>
<tr>
<td>BASIC/APL (combined machines only)</td>
<td>APL</td>
</tr>
<tr>
<td>DISPLAY REGISTER/NORMAL</td>
<td>NORMAL</td>
</tr>
</tbody>
</table>

If your 5110 has the BASIC/APL switch, it can execute both BASIC and APL language statements. The language to be used is selected by the user before power up or during the restart sequence.

Make sure your 5110 is plugged in and turn power on. If power is already on, press RESTART and wait about 20 seconds. During this time, the 5110 performs internal checks to make sure it is operating correctly.

After 30 seconds, if the message CLEAR WS has not appeared in the lower left corner of the display screen, an error has been detected during the internal checks. In this case, press RESTART. The 5110 will perform the internal checks again. If the CLEAR WS message does not appear after several tries, call your service representative.

Display
ENTERING AND DISPLAYING DATA

First, let's look at the display screen. Normally, information displayed by APL begins at the left edge of the display screen, and the input from the keyboard is indented when it is displayed. The small horizontal flashing line indicates the position on the line where the next input from the keyboard will be displayed. This flashing line is called the cursor. The cursor moves as each character is displayed.

The display screen can contain up to 16 lines of data. Each line has 64 positions across the display screen. The bottom two lines are used to display input, and the remaining 14 lines contain a history of the operations you have performed.

There are 128 positions available for input from the keyboard; that is, there are 64 positions available on line 1 and 64 positions on line 0. When position 64 of line 1 is used as you enter data from the keyboard, the cursor moves to the left margin of line 0. The cursor is then at position 65 of the possible 128 positions available for input.
Now let's enter some data into the 5110 using the numeric keyboard and the arithmetic function keys. Press the following keys:

```
2 1 3
```

Notice that the characters are displayed as each key is pressed. To process the data you just keyed, you must press the EXECUTE key. Press the EXECUTE key now.

The display screen will look like this:

```
CLEAR WS
2+3
5
...
```

Notice that the expression you entered, 2+3, appears indented on the display screen; the answer, 5, appears on the left margin of the next line; and the cursor appears on the next line. The information displayed moves up each time the EXECUTE key is pressed.

Enter and execute the expression 125+75 by pressing the following keys:

```
1 2 5 7 5 EXECUTE
```

The display screen will look like this:

```
CLEAR WS
2+3
5
125+75
200
...
```
The appearance of your display can be changed by the REVERSE DISPLAY and L32 64 R32 switches on the control panel. The REVERSE DISPLAY switch allows you to change from black characters on a white background to white characters on a black background and vice versa. Change the switch and select the type of display you feel most comfortable with. You may have to adjust the brightness control as you change from one to the other.

Now, watch the display as you set the L32 64 R32 switch to the L32 position. With the switch in this position, the leftmost 32 characters on each line are displayed with an extra space between each character. The rightmost 32 characters on each line will not be displayed. With the switch in the L32 position, your display should look like this:

```
CLEAR   WS
  2 + 3
  5     1 2 5 + 7 5
  2 0 0 ...
```

In the R32 position, the rightmost 32 characters are displayed with a space between each character. Now, set the switch in the R32 position and notice that the display is blank because there were no characters in the rightmost 32 positions of the display screen.

Return the switch to the 64 position, and notice that all characters are displayed without the space in between. For exercises in the remainder of this book, keep the switch in the 64 position.

There are two keys above the numeric keys that move the display line up or down. The up arrow (scroll up key) moves the display up one line and the down arrow (scroll down key) moves the display down one line. As the lines are moved up or down, the displayed information on any line that is moved off the display screen is lost. Also, the cursor returns to position 7 on line 1 when either scroll key is used. Either key continues to move the display lines if it is held down. Now use the down arrow to move the display down one line.

The display will look like this:

```
CLEAR   WS
  2 + 3
  5     1 2 5 + 7 5
  2 0 0 ...
```

The value 200 is now on the input line and can be used as input. Notice that input can begin in any position on the line.
Now press the following keys:

![Image showing keys: 1 5 0]

The display screen will look like this:

```
CLEAR WS
2+3
5
125+75
200 +50
250 
```

Now that you are familiar with the display screen, only the line or lines being discussed will be shown.

CORRECTING KEYING ERRORS

The IBM 5110 has a number of very useful features that allow you to correct errors made when data was entered. On a line-by-line basis, at any time, you can:

- Replace a character
- Delete a character
- Insert a character

Replacing a Character

To replace a character, move the cursor with the backspace key or forward space key, until the cursor is positioned at the incorrect character. The cursor moves one character space in the direction of the arrow each time the appropriate key is pressed. These keys continue to move the cursor if they are held down. When the cursor is at the incorrect character, you replace the incorrect character by simply keying the correct character.
For example, you want to do the problem 22+12. But you press the following keys:

2 2 1 1

The display screen looks like this:

22+11...

To correct the error, the cursor must be moved back one position (under the second 1) so that the character can be rekeyed. Now press the backspace key one time. Note that the cursor is replaced by a flashing character. The flashing character serves the same function as the cursor; it indicates the position on the line where the next input from the keyboard will be displayed. Now to correct the error and execute the problem, press the following keys:

Deleting a Character

To delete a character, you also use the backspace key or forward space key to move the cursor. Once the cursor is in the position of the character to be deleted (the character is flashing), hold down the CMD key and press the backspace key once. The character is then deleted and any characters to the right are shifted one position to the left to close up the space left by the deletion.
For example, you want to do the problem 13+45. But you press the following keys:

1 2 3 + 4 5

The display screen looks like this:

123+45 ...

Press the backspace key and move the cursor (flashing character) back to the 2. Look at the labels that appear above the backspace and forward space keys: DELETE and INSERT. To delete the 2, hold down the CMD key while you press once.

The display screen looks like this:

13+45

This character is flashing.

Now press the EXECUTE key to execute the problem.

Inserting a Character

To insert a character, position the cursor using the backspace key or forward space key; then hold down the CMD key and press the forward space key once. This operation moves the flashing character (and all other characters to the right of it) one position to the right, creating the space you need to insert one character. The cursor is not moved. Now, to insert the character, simply press the desired key.
For example, you want to do the problem 123x6. But you press the following keys:

```
1 3 X 6
```

The display screen looks like this:

```
13×6–
```

To correct the error, press the backspace key and move the cursor (flashing character) back to the 3. Look at the labels that appear above the backspace and forward space keys: DELETE and INSERT. To perform the insert function, with the cursor positioned at the 3, hold down the CMD key while you press once.

The display screen looks like this:

```
1…3×6
```

Now to correct the keying error and execute the problem, press the following keys:

```
? EXECUTE
```
There is one more way to correct a keying error. If you make several errors part way through the line, you can backspace the cursor to the character following the last correct character and then press the ATTN (attention) key. Everything from the cursor position to the end of the input line will be cleared from the display.

Since the data from the input line is not processed until the EXECUTE key is pressed, you can visually verify any input before it is processed. However, if you do press the EXECUTE key before you notice a mistake, you can simply enter the input again or you can use the down arrow \( \downarrow \) (scroll down key) to move the input back down to the input line to correct it. Either way, you must press the EXECUTE key again.

For example, you want to do the problem 135+280, but you enter and execute 134+280. The display screen looks like this:

\[
\begin{align*}
134+280 \\
4.14 \\
... 
\end{align*}
\]

To correct the input, press the down arrow \( \downarrow \) three times to clear the result from the screen. The display screen now looks like this:

\[
\begin{align*}
134+280 \\
... 
\end{align*}
\]

Then press the up arrow \( \uparrow \) once to move the original input back up to the first input line so that it can be corrected.
ENTERING LOWERCASE ALPHABETIC CHARACTERS

Although only the standard APL alphabetic characters are shown on the 5110 keyboard, you can enter lowercase alphabetic characters by changing the 5110 to lowercase character mode. One way to change the 5110 to lowercase character mode is to press the HOLD key (the characters HOLD are displayed in the lower left corner) and then hold down the shift key and press the scroll down key. The 5110 is now in lowercase character mode. For example, press the key. The display screen looks like this:

a

Now, hold down the shift key and press the key. The display screen looks like this:

aA

Finally, hold down the command key and press the key. The display screen looks like this:

aAα

In this example, you are not going to execute the data just entered from the keyboard because you will get an error. Instead, press the scroll up key once to remove the data from the input line. Now, to return the 5110 to the standard APL character mode, press the HOLD key and then hold down the shift key and press the scroll up key. The 5110 is now in standard APL character mode.

Note: See Console Control in the IBM 5110 APL User's Guide, SA21-9302, for more information on how to enter lowercase characters.
From this point on, we will discuss the APL language and use examples in the following format to illustrate what we are discussing. You enter the expressions that are indented. The results displayed on your 5110 should be the same as the results shown in this manual.

EXAMPLES:

\[
\begin{align*}
    3 + 4 & \rightarrow \text{Expressions To Be Entered} \\
    7 & \rightarrow \text{Results}
\end{align*}
\]

Remember, the data you key is not processed until the EXECUTE key is pressed.
Chapter 2. Introducing the APL Language

TYPES OF FUNCTIONS IN APL

There are two types of functions in APL: user-defined functions (programs) and those that are built into the APL language. The APL built-in functions are denoted by special symbols. User-defined functions are discussed later, in Chapter 7.

The built-in functions operate on data supplied, called arguments. For example:

2 + 3

Right Argument

Built-in Function (addition)

Left Argument

ADDITION, SUBTRACTION, MULTIPLICATION, AND DIVISION

Four commonly used built-in functions (+ - × ÷) perform the normal arithmetic operations when they are used. These symbols are located on the top row of the alphabetic keys and also to the right of the numeric keys.
EXAMPLES:

\[ 3+6 \quad \text{Add 3 and 6.} \]

\[ 3 \times 6 \quad \text{Multiply 3 times 6.} \]

\[ 8-4 \quad \text{The right argument is subtracted from the left argument.} \]

\[ 4-8 \quad \text{The high horizontal bar is the negative sign. Compare it with the minus which is the symbol for subtraction; the negative sign appears near the top of the character instead of on the center line.} \]

\[ 8 \div 4 \quad \text{The left argument is divided by the right argument.} \]

\[ 4 \div 8 \]

As you have seen in the example, the negative sign is different from the minus. When you are doing arithmetic operations in APL, do not use the minus to represent negative numbers or the negative sign for a subtract operation.

Problems: Using Addition, Subtraction, Multiplication, and Division

1. Find the total number of cars that a dealer sold during one week if his daily sales were 3, 5, 2, 6, 7, 3 and 4.

2. Find the net number of cars removed from the same dealer’s lot if 20 people had trade-ins.

3. Find the dealer’s average profit per car if he made a total profit of $2700 for the sales in problem 1.

4. Find the dealer’s total earnings if he made $20 on each car sold.
Possible Solutions

Problem 1:

\[ 3+5+2+6+7+3+4 = 30 \]

Problem 2:

\[ 30 \div 20 = 1.5 \]

Problem 3:

\[ 2700 \div 30 = 90 \]

Problem 4:

\[ 20 \times 30 = 600 \]

ANOTHER ARITHMETIC FUNCTION—RAISING A NUMBER TO A POWER

Another arithmetic function that you are probably familiar with is raising a number to a power. In APL, you use the \( \times \) function to raise the left argument to the power specified by the right argument.

EXAMPLES:

\[ 3 \times 2 \rightarrow 3 \text{ raised to the second power.} \]

\[ 2 \times 3 \rightarrow 2 \text{ raised to the third power.} \]
Finding the Root of a Number

You can use the power function \(*\) to find the root of a number. To do this, you simply raise the number to the power \(1/n\), where \(n\) is the root you want to find.

EXAMPLES:

- \(4^{(1/2)}\) \rightarrow The square root of 4.
- \(4^{0.5}\) \rightarrow Another way to enter the instruction to find a square root of a number (.5 is the same as \(1/2\)).
- \(8^{(1/3)}\) \rightarrow The cube root of 8.

STORING DATA IN THE 5110 FOR LATER USE

You can store data, either direct input that you enter from the keyboard or the result of a calculation. These stored items are called variables. Each variable has a name associated with it. Whenever you use the name of a variable, APL supplies the value associated with that name. A variable name can be up to 77 characters long (with no blanks); the first character must be alphabetic; the remaining characters can be any combination of alphabetic and numeric characters. It is good practice to use names that represent the data you are storing. For example, if you want to store a value that is the area of a rectangle you might use the name AREA; or if you want to store some sales data, you might use the name SALES.

You create a variable by assigning the data to a name. To assign a value to a name, you use the assignment arrow \(<-\). The value to the right of the \(<-\) is assigned to the name to the left of the \(<-\).
EXAMPLES:

**PRICE** ← 99.50
**SALES** ← **PRICE** × 10
**PRICE**

99.5

**SALES**

995

After you press the EXECUTE key, you have created a variable named **PRICE** with a value of 99.50.

The result of a calculation can also be assigned to a variable.

If you want to know the current value of a variable, you simply enter the name of the variable.

**PRICE** ← 86.75
**PRICE**

86.75

**PRICE** ← **PRICE** + 10
**PRICE**

96.75

You can change the value of a variable the same way you assigned the original value.

You can also use the variable and change its value in the same instruction.

You cannot use a name as a variable if it does not have a value assigned to it.

**VALUE** ← **ERROR**

**COST** ← **SALES**

^

The error message indicates why the instruction failed.

The caret (^) indicates where the instruction failed.

Note: Do not be concerned at this time about the error message that is displayed; all of the 5110 APL error messages and suggested user's responses are described in the *IBM 5110 APL Reference Manual*, SA21-9303.

PERFORMING SEVERAL FUNCTIONS IN THE SAME EXPRESSION

In the preceding examples, only one arithmetic function was used in each example. However, you are not restricted to writing expressions with only one function. Any number of functions can occur in the same instruction. As soon as you use more than one function, however, you must be concerned about the order in which they are used. In APL, the rightmost function in any expression is executed first, then the next rightmost, and so on.
EXAMPLES:

Order of execution is right to left.

18

\[ 3 \times 2 + 4 \rightarrow 4 \text{ is added to 2, and that result is multiplied by 3.} \]

10

\[ 4 + 3 \times 2 \rightarrow 3 \text{ is multiplied by 2, and that result is added to 4.} \]

Remember that an APL function uses as its right argument the result of the expression to its right.

SPECIFYING THE ORDER OF EXECUTION—USING PARENTHESES

In APL, parentheses are used the same way as they are in conventional arithmetic: the expressions inside the parentheses are executed before the expressions immediately outside them.

EXAMPLES:

10

\[ (3 \times 2) + 4 \rightarrow \text{The expression } 3 \times 2 \text{ is evaluated first and the result is added to 4.} \]

14

\[ (4 + 3) \times 2 \rightarrow \text{The expression } 4 + 3 \text{ is evaluated first and the result is multiplied by 2.} \]

Remember, the rule of the order of execution is from right to left with the expressions in parentheses resolved first and from right to left as they are encountered.

USING STRINGS OF NUMBERS AND TABLES

A powerful feature of APL is the way it handles strings and tables of data. So far, you have used APL with only single numbers (called scalars): but APL also works with strings of numbers (vectors) and tables (matrices). The functions you have performed using single numbers are simply extended to each number in a string or a table. For example, if you have a string of numbers assigned to a variable named SALES, you can add 2 to each number in the string by simply entering 2+SALES.
Using APL with Strings of Numbers (Vectors)

A string of numbers is called a vector. When you enter a string of numbers, there must be at least one blank between each number; each number is called an element of the vector.

EXAMPLES:

1 44 2 9 35
1 44 2 9 35
STRING +144 16 39 2
STRING
144 16 39 2
SALES +125 220 316 90
SALES × 10
1250 2200 3160 900

SALES
125 220 316 90
PRICE +.50 1.00 .75 1.10
TOTAL + SALES × PRICE
TOTAL
62.5 220 237.99

1 2 4 + 4 5 6
5 7 10
124 + 456
580

1 2 3 + 4 5
LENGTH ERROR
1 2 3 + 4 5

You have entered a five-element vector (a string of five numbers).

A vector can be assigned to a variable name.

Each element (number) in the vector can be operated on by a single number.

Note that the value of SALES has not changed.

Each element in a vector can be operated on by the corresponding element in another vector with the same number of elements.

There must be at least one blank between the elements of the vector, or the result will be different.

You cannot use two vectors that do not have the same number of elements unless one of the arguments is a single number (single element).
Problems: Using Strings of Numbers

1. Find the squares of the numbers from 1 to 5.

2. Find the squares, cubes, and fourth powers of the numbers 2 and 3.

3. A small mutual fund broker specializes in five funds. He wants to know how much of each fund he had sold at the close of the day. By 4:00 PM, he had sold $1500, $3200, $1200, $2300, and $2400, respectively, of the five funds. In the last hour of the day, he sold $100, $500, $300, $200 and $0 of the respective funds. Write a single APL statement to determine his closing sales figures for each fund.

4. The five funds in problem 3 sold for $7.30, $11.58, $3.45, $2.17 and $5.56 per share. How many shares of each fund were sold?

5. The broker receives the following percentages of commission on the five funds: 3.25, 2.5, 3.0, 3.75 and 3.5. How much did he earn from each fund today? What are his total earnings for the day?

Possible Solutions

Problem 1:

```
  1 2 3 4 5*2
1 4 9 16 25
```

Problem 2:

```
  2 3*2
4 9

  2 3*3
8 27

  2 3*4
16 61

or

  2*2 3 4
4 8 16

  3*2 3 4
9 27 81
```
Problem 3:

1500 3200 1200 2300 2400+100 500 300 200 0
1600 3700 1500 2500 2400

Problem 4:

1600 3700 1500 2500 2400+7.30 11.58 3.45 2.17 5.56
219.18 319.52 434.78 1152.1 431.65

Problem 5:

1600 3700 1500 2500 2400+0.325 0.0250 0.0300 0.0375
52 92.5 45 93.75 84
52.00+92.50+45.00+93.75+84.00
367.25

Using APL with Tables of Numbers (Matrices)

A table of numbers is sometimes called a matrix. The numbers in the matrix are arranged in rows and columns; each number is called an element of the matrix.

You can use the reshape $\rho$ function to create matrices. The left argument specifies the number of rows and columns, and the right argument specifies the data or variable name for the data to be placed in the matrix.
EXAMPLES:

The first number in the left argument specifies the number of rows; the second number specifies the number of columns.

The right argument specifies the values to be placed element by element into the rows of the matrix.

There must be a blank between the numbers specifying rows and columns.

If there are not enough elements in the right argument to fill the matrix, the elements are repeated.

If there are more elements in the right argument than are required to fill the matrix, only the first (leftmost) elements are used.

The reshape function can also be used to create a vector.

The number of elements in the vector.

Each element in the matrix can be operated on by a single number (remember, the value of MATRIX is not changed).

Remember that APL executes an expression from right to left—the result of NUMBERS+5 is used as the right argument for the reshape function.

Each element in a matrix can be operated on by the corresponding element in another matrix of the same shape.
EXAMPLES—continued

\[
\begin{align*}
\text{LESS + 2 2 \# NUMBERS} \\
\text{LESS} \\
\begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix} \\
\text{MATRIX \# NUMBERS} & \quad \text{A matrix and a vector} \\
\text{RANK ERROR} \\
\text{MATRIX \# NUMBERS} \\
\wedge \\
\text{MATRIX \# LESS} & \quad \text{two matrices that do not have the same shape (number of rows and columns) cannot be used unless one of the arguments is a single number.}
\end{align*}
\]

REFERRING ONLY TO CERTAIN NUMBERS IN A STRING OR TABLE OF NUMBERS (INDEXING)

Indexing is a way to refer to only certain elements in a string or table by specifying the position of the element you want. The numbers you use to specify the positions of the elements are called index numbers. These index numbers are enclosed in brackets \([\ ]\) following the vector or matrix to which they apply.

EXAMPLES:

\[
\begin{align*}
\text{TEMP \# 68 74 78 65 80 85 72} \\
\text{TEMP[C23]} \quad \text{You can refer to a single element.} \\
\text{TEMP[C3 1 23]} \\
\text{78 60 74} \quad \text{You can refer to several elements. Notice that the elements are displayed in the order in which you indexed them.} \\
\text{TEMP[C23]+TEMP[C3 1 23]} \\
\text{152 142 148} \\
\text{TEMP[C71]+88} \\
\text{TEMP} \\
\text{68 74 78 65 80 85 88} \\
\text{TEMP[C3 63+70]} \\
\text{TEMP[C3 61]} \\
\text{70 70} \\
\end{align*}
\]

Introducing the APL Language 27
EXAMPLES—continued

Notice that the new values are assigned in the same order as the index numbers.

For a matrix, you need an index number for the rows and an index number for the columns—these numbers are separated by a semicolon.

Remember, we have previously assigned a value to NUMBERS.

Left side of the ; specifies the row(s).

Right side of the ; specifies the column(s).

You can refer to a single element or you can refer to several elements. In this case, you have referred to the second and third elements in the third row.

Notice that when you refer to more than one row and more than one column, your result is a matrix.
EXAMPLES—continued

If you do not specify a column, you get the whole row.

If you do not specify a row, you get the whole column.

These values (the third column) are displayed horizontally, because they are a string of numbers (vector).

Note: Even when you select entire rows or columns, the semicolon is still required to make it clear whether the index number is for the rows or columns.

You can index and use other functions in the same expression.

You can change the value of elements in a matrix.

YOU ARE NOT LIMITED TO USING ONLY NUMBERS

Although the examples so far have used only numeric data, APL also works with character data. Character data, for example, can be used for headings on a table or to create a list of names. When you enter character data, you must enclose the data in single quote characters (''). These single quote characters indicate that the data is character data and is not a variable name, a number, or a function. When character data is displayed, the single quote marks do not appear.

Character data, like numeric data, can be a single character (scalar), a string of characters (vector), or a table of characters (matrix). Unlike numeric data, when you have a character vector or matrix, each character is a separate element and is not separated from the other elements by a blank. In fact, a blank in the character data is also a character (blank character).
EXAMPLES:

A

' A' ← Single character (scalar).

ABC

' ABC' ← String of three characters (three-element vector).

2+3

' 2+3' ← This expression does not yield a result of 5, because the values are characters, not numbers.

NUMBER+456

' 123' + NUMBER

DOMAIN ERROR ← You cannot add character data and numeric data.

DON'T DO THAT

'DON'T DO THAT'

THANKS+ 'YOU ARE WELCOME'

THANKS

YOU ARE WELCOME

To place a quote within the character string, you must use a pair of quotes.

Character data can be assigned to a variable name.

NAMES+ 'SAM JOHN JACK TOM'

MATRIXN+4 NAMES

MATRIXN

Blank characters.

Create a character matrix, each row represents a name.

SAM
JOHN
JACK
TOM

NAMES[5 6 7 8]

MATRIXN[2;1]

Indexing works with character data also.

So far, you have used APL with some common arithmetic functions. You have also seen how APL works with scalars (single data items), vectors (strings of data), and matrices (tables of data). However, you are not limited to just the functions we have discussed so far. In the following chapters, you will be introduced to more things you can do with APL.
Chapter 3. APL Functions That Require One Argument

In this chapter you will use some APL functions to do the following:

- Determine the whole numbers nearest a fraction.
- Sort a vector into ascending or descending order.
- Generate a random number.
- Find the shape of an existing variable.

There are additional APL functions that require one argument; however, these functions will be discussed later, in Chapter 6.

HOW MANY ARGUMENTS ARE REQUIRED BY AN APL BUILT-IN FUNCTION?

In this chapter, you will use APL functions with one argument. In the next chapter, you will use some of the same APL function symbols with two arguments. As you will see, these symbols perform different APL functions when they are used with one and with two arguments. When you use an APL function with one argument, the argument must be to the right of the function symbol.

APL FUNCTION SYMBOLS THAT ARE A COMBINATION OF TWO CHARACTERS

Some of the APL function symbols you will use are a combination of two characters. You remember that when correcting keying errors, if you positioned the cursor at a certain character and pressed another key, a new character would replace the original character. However, certain APL symbols require two characters, one struck over the other. For these symbols, key the first character, backspace, and key the second character. It does not matter in which order the characters are keyed. The symbols that are a combination of two characters are called overstruck characters. Appendix A shows the overstruck characters and the keys required to enter them.

Note: If you key an overstruck character and then want to change it, you can position the cursor at the character and key another character. The new character will replace the overstruck character.
DETERMINING THE WHOLE NUMBERS NEAREST A FRACTION

When you want to disregard the fractional part of a number and just consider the nearest whole number, you can use the floor \( \lfloor \cdot \rfloor \) and ceiling \( \lceil \cdot \rceil \) functions. The floor function will round the number down to the next smaller whole number and the ceiling function will round the number up to the next larger whole number.

**EXAMPLES:**

\[
\begin{align*}
3 \times 3.529 & \quad \lfloor \cdot \rfloor \\
3 \times 4 & \quad \lceil \cdot \rceil \\
3 \times 3 & \quad \lfloor \cdot \rfloor \\
3 \times 3.529 & \quad \lceil \cdot \rceil \\
\end{align*}
\]

If the number is already a whole number, the result is the same as the argument.

The result for the floor and ceiling functions is determined according to the number's position on the number line:

\[
\begin{array}{cccccc}
\text{(smaller)} & 4 & 3 & 2 & 1 & 0 & 1 & 2 & 3 & 4 \\
\text{(larger)} & & & & & & & & & \\
\end{array}
\]

Rounding to the Nearest Whole Number

It is a common practice to round numbers to the nearest whole number. You can do this by adding .5 to the number and then using the floor function.

**EXAMPLES:**

\[
\begin{align*}
\times 4.4 + .5 & \quad \text{Rounds 4.4 to the nearest whole number.} \\
\times 4 & \\
\times 4.6 + .5 & \quad \text{Rounds 4.6 to the nearest whole number.} \\
\times 5 & \\
\times 4.4 + .5 & \\
\times 4 & \\
\times 4.6 + .5 & \quad \text{These examples could also be entered this way.} \\
\times 5 & \\
\end{align*}
\]
SORTING A VECTOR IN ASCENDING OR DESCENDING SEQUENCE

The grade up \( \uparrow \) and the grade down \( \downarrow \) functions can be used to sort a numeric vector into ascending or descending sequence, because they give you the indices of the argument in ascending or descending order.

EXAMPLES:

\[ A \text{+} \{80 \ 45 \ 62 \ 37 \ 29 \ 74 \ 58 \ 15 \ 96\]  
\[ \downarrow A \quad \Rightarrow \quad 8 \ 5 \ 4 \ 2 \ 7 \ 3 \ 6 \ 1 \ 9 \]  
\[ A \text{+} A[\downarrow A] \rightarrow B \]  
\[ B \rightarrow \{15 \ 29 \ 37 \ 45 \ 58 \ 62 \ 74 \ 80 \ 96\]  
\[ \downarrow A \rightarrow \{9 \ 1 \ 6 \ 3 \ 7 \ 2 \ 4 \ 5 \ 8\]  
\[ C \rightarrow A[\downarrow A] \rightarrow \{96 \ 80 \ 74 \ 62 \ 58 \ 45 \ 37 \ 29 \ 15\]  

Remember, when indexing elements in a vector, the index numbers or the index expression must be enclosed in \( [\] \).
GENERATING A RANDOM NUMBER

To generate a random number, you can use the roll function ?., which generates a random number between 1 and the value of the argument.

EXAMPLES:

\[ X + ?6 \]  Generates a number between 1 and 6.
\[ X \]
\[ 5 \]  The result can be any number between 1 and 6.
\[ X + ?6 \]
\[ 6 \]
\[ 6 \]  When this function is used with a vector, a random number is generated for each element.
\[ X \]
\[ 1 \ 3 \ 1 \ 3 \]

GENERATING CONSECUTIVE NUMBERS

There are times when you will want to generate a vector of consecutive numbers from one value to another value. You can do this by entering an instruction like this:

\[ \text{VECTOR} \rightarrow 1 \ 2 \ 3 \ 4 \ 5 \ 6 \ 7 \ 8 \]
\[ \text{VECTOR} \rightarrow 1 \ 2 \ 3 \ 4 \ 5 \ 6 \ 7 \ 8 \]

However, you can also use the index generator function \( \uparrow \), which generates consecutive numbers from 1 to the value specified by the argument.

EXAMPLES:

\[ \uparrow 8 \]  Eight consecutive numbers
\[ 1 \ 2 \ 3 \ 4 \ 5 \ 6 \ 7 \ 8 \]
\[ \text{VECTOR} \rightarrow 5 + \uparrow 5 \]
\[ \text{VECTOR} \rightarrow 6 \ 7 \ 8 \ 9 \ 10 \]
\[ 2 \times \uparrow 6 \]  First 6 powers of 2
\[ 2 \ 4 \ 8 \ 16 \ 32 \ 64 \]
Generating an Empty Vector

An empty vector is just that—a vector with nothing in it (no elements). Why have a vector with nothing in it? As you will see later, when joining two items together or branching in a user-defined function, there are times when you will want to generate an empty vector. One way to generate an empty vector is to use 1 0.

EXAMPLES:

```
NAME
VALUE ERROR ← An error occurs if you use a variable name that does not have a value assigned.
NAME
^
NAME ← 1 0 ← Generate an empty vector.
NAME

The result is a blank display line (no value).
```

FINDING THE SHAPE OF AN EXISTING VARIABLE

As you learned in Chapter 2, the left argument of the reshape function determined the number of elements in a vector or the number of rows and columns in a matrix. Thus, the number of elements in a vector or a matrix is referred to as the shape of the vector or matrix. For example, the shape of matrix M, which has two rows and three columns, is: 2 3. To find the shape of an existing variable, you can use the shape function ρ.

EXAMPLES:

```
SCALAR ← 4
VECTOR ← 2 4 6 8
MATRIX ← 2 3 6
ρ SCALAR
ρ VECTOR
ρ MATRIX
4 ← Number of elements in the vector.
2 3 ← Number of rows and columns in the matrix.

EMPTY ← 1 0 ← Generates an empty vector.
EMPTY

ρ EMPTY
0 ← Number of elements in an empty vector.
```
Chapter 4. APL Functions That Require Two Arguments

In this chapter you will use some APL functions that require two arguments. You can use these functions to do the following:

- Compare the arguments to determine whether one is equal to, greater than, or less than the other argument.
- Process logical data—true (1’s) and false (0’s) data.
- Find the larger of two numbers.
- Find the smaller of two numbers.
- Find the index of a value in a vector.
- Generate a random sequence of numbers.
- Compress (select certain elements from) a vector or matrix.
- Expand a vector or matrix by inserting zeros or blanks.
- Join two items together.
- Find the logarithm of a number.

There are additional APL functions that require two arguments; however, these functions will be discussed later, in Chapter 6.
RELATIONAL FUNCTIONS

When solving problems with APL, you might want to test the relationship between two values. For example, you might want to test a counter to see if it has reached a certain value; or you might want to do something different in the solution to your problem, depending on whether a certain condition is true or false. The following APL functions are used to test the relationship between two values:

<table>
<thead>
<tr>
<th>Function</th>
<th>Symbol</th>
<th>Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Greater than</td>
<td>&gt;</td>
<td>&gt;</td>
</tr>
<tr>
<td>Less than</td>
<td>&lt;</td>
<td>&lt;</td>
</tr>
<tr>
<td>Greater than or equal to</td>
<td>≥</td>
<td>≥</td>
</tr>
<tr>
<td>Less than or equal to</td>
<td>≤</td>
<td>≤</td>
</tr>
<tr>
<td>Equal to</td>
<td>=</td>
<td>=</td>
</tr>
<tr>
<td>Not equal to</td>
<td>≠</td>
<td>≠</td>
</tr>
</tbody>
</table>

When these functions are used, the relationship between the two values is evaluated, and a 1 results if the relationship is true, and a 0 if false.
EXAMPLES:

```
A = 10
B = 20
A = B

0
A = B - 10
1
A ≤ B
1
A ≠ B
1
A ≥ B
0
A = 'ABC'
B = 'DEF'
A = B

0 0 0
A ≠ B
1 1 1
```

The = and ≠ functions also work with character data. Remember, each element is compared with the corresponding element in the other argument.
Why Two Numbers Identical in Appearance Are Not Always Equal

APL stores all numeric values with an internal precision of 16 decimal digits; however, decimal values with more than five significant digits are normally rounded off to five digits before they are displayed. Thus, occasionally, different numbers will look alike when displayed.

EXAMPLES:

\[
\begin{align*}
A &+ 1 \div 3 \\
B &+ 0.33333 \\
A &+ 0.33333 \\
B &+ 0.33333 \\
A &=*B \\
5 &\text{PP} \\
&\text{PP is a system variable that determines how many significant digits will be displayed. This variable is automatically set to 5 when the power is turned on or RESTART is pressed. (The system variables are discussed in Chapter 9.)} \\
&\text{PP}+15 \\
A &+ 0.333333333333333 \\
B &+ 0.33333 \\
&\text{PP}+5 \\
&\text{Set the PP system variable so that 15 significant digits will be displayed.} \\
&\text{Set the PP system variable back to 5.} \\
&\text{Notice the difference between the two values.} \\
&\text{Remember, the value displayed may not be the exact value that the 5110 has stored for the variable.} \\
&\text{An Example Using a Relational Function} \\
&\text{Suppose the correct answer to a problem has been stored as a variable called RIGHT, and the answer supplied by a student has been stored as a variable called ANSWER. To keep track of the student’s score, you want to add 1 to his score if his answer is the same as the right answer; otherwise, you want to leave his score unchanged.}
\end{align*}
\]
If the student got the problem right, it is true that \(\text{ANSWER} = \text{RIGHT}\). To add 1 to his score only if his answer is equal to the right answer, you could enter this instruction:

\[
\text{SCORE} \leftarrow \text{SCORE} + \text{ANSWER} = \text{RIGHT}
\]

Then the amount added to \(\text{SCORE}\) is 1 when the two values are equal and 0 when they are not equal.

Suppose that instead of adding 1 when the student is right, you want to give some problems more weight than others. The weight of the current problem is stored under the variable \(\text{WEIGHT}\). If the student gets the problem right, you want to add \(\text{WEIGHT}\) to his score; otherwise, you want to leave his score unchanged. You could enter this instruction:

\[
\text{SCORE} \leftarrow \text{SCORE} + \text{WEIGHT} \times \text{ANSWER} = \text{RIGHT}
\]

If the student’s answer is equal to the right answer, then \(\text{ANSWER} = \text{RIGHT}\) has the value 1, so the amount added is \(\text{WEIGHT} \times 1\). But if the answers are not equal, then the amount added is \(\text{WEIGHT} \times 0\), which is 0.

**LOGICAL FUNCTIONS**

The logical functions take only ones and zeros as arguments and are used to check for certain conditions. (They usually check the results of relational functions.) The fundamental logical functions are:

<table>
<thead>
<tr>
<th>Function</th>
<th>Symbol</th>
<th>Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>And</td>
<td>(\wedge)</td>
<td>(0)</td>
</tr>
<tr>
<td>Or</td>
<td>(\vee)</td>
<td>(0)</td>
</tr>
</tbody>
</table>

In our discussion of the logical functions, we will use tables like the following one to show the possible results of the logical functions:

<table>
<thead>
<tr>
<th>Logical Function</th>
<th>(\wedge)</th>
<th>(0)</th>
<th>(1)</th>
<th>Values of the Right Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>(0)</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>Values of the Left Argument</td>
</tr>
<tr>
<td>(1)</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>Results</td>
</tr>
</tbody>
</table>
To use this table, simply find the value of the right argument on top of the table and the value of the left argument on the left side of the table. Then, follow the column represented by the right argument down and the row represented by the left argument across. Where they intersect is the result of the logical function when those values are supplied as arguments. For example, find out what the result of $1 \land 0$ is as follows:

And $\land$

The And function is used to check for two conditions being true.

For example, suppose you want to know when the items that cost more than $100.00 have a quantity less than 10. You could use the following instruction:

$$(COST > 100) \land (QUANTITY < 10)$$

Notice how the parentheses in this instruction specify the order of execution.
EXAMPLES:

\[
\begin{align*}
\text{QUANTITY} & \geq 8 \\
\text{COST} & \leq 120 \\
(COST > 100) & \land (QUANTITY < 10) \\
1 & \quad \text{Both conditions are true.}
\end{align*}
\]

\[
\begin{align*}
\text{QUANTITY} & \geq 25 \\
(COST > 100) & \land (QUANTITY < 10) \\
0 & \quad \text{At least one condition is not true.}
\end{align*}
\]

The `Or` function is used to check for at least one of two conditions being true.

For example, suppose you want to know when either the inventory for a certain item is less than 10 or the orders for that item exceed the inventory. You could use the following instruction:

\[
(INVENTORY < 10) \lor (ORDERS > INVENTORY)
\]

- The result is 1 when the orders are greater than the inventory.
- The result is 1 when the inventory is less than 10.
EXAMPLES:

\[
\begin{align*}
\text{INVENTORY} &< 15 \\
\text{ORDERS} &< 5 \\
(\text{INVENTORY} < 10) \lor (\text{ORDERS} > \text{INVENTORY})
\end{align*}
\]

0 \quad \text{Both conditions are false.}

\[
\begin{align*}
\text{ORDERS} &< 25 \\
(\text{INVENTORY} < 10) \lor (\text{ORDERS} > \text{INVENTORY})
\end{align*}
\]

1 \quad \text{At least one of the conditions is true.}

Problems: Using Relational and Logical Functions

1. It is vital to build error checking into all space systems to prevent catastrophe. For example, two indicators checking one condition are commonplace. If either or both of the indicators show danger, action must be taken.

Assume that the \( A \) indicator is over its limit at 1.3725 amperes and the \( B \) indicator is over its limit at 1.5365 amperes. Enter an expression that will result in a 1 when one or both indicators are outside their limits; the indicators read 1.3732 and 1.5362, respectively.

2. A survey was conducted by the PTA in which the teacher and the parent of the child each evaluated ten of the child’s characteristics.

One child’s teacher replied 1, 0, 1, 1, 0, 1, 0, 0, 1, 0 to the questions dealing with his characteristics. His parent answered 1, 0, 0, 1, 0, 1, 1, 0, 0, 0.

Show which questions the teacher and parent both replied to with a 1.

Possible Solutions

Problem 1:

\[
(1.5365 \leq 1.5362) \lor 1.3725 \leq 1.3732
\]

\[
1 \quad \text{(Result)}
\]

Problem 2:

\[
(\text{\{10\}X1}
0 1 1 0 0 1 0 0 1 0 0 1 0 1 1 0 0 0
1 0 0 0 4 0 6 0 0 0 0
\]

APL Functions That Require Two Arguments 43
FINDING THE LARGER OF TWO NUMBERS

The result of the maximum \( \max \) function is the larger of the two arguments.

EXAMPLES:

\[
\begin{align*}
A & \leftarrow 5 \\
B & \leftarrow 6 \\
\max(A, B) & \leftarrow 6 \\
\max(B \times B, A \times A) & \leftarrow 36
\end{align*}
\]

To see how you could use the maximum function, suppose you work for a department store. Each month the store calculates the amount charged and the amount paid by each customer. Your job is to find the difference between the total accumulated charges and the total accumulated payments for each customer. This difference is stored in a variable named BALDUE. The store also charges a service charge of 1.5% of the unpaid balance each month. You could find this charge with the following instruction:

\[
\text{CHARGE} \leftarrow \text{BALDUE} \times 0.15
\]

However, some of the customers have overpaid their bills. For them, BALDUE is a negative number and shows as a credit on their monthly statements. If you calculate the service charge by the instruction just shown, you will be paying them interest at a rate of 1.5%. Instead, the store prefers to calculate the service charge as 1.5% of the balance due or of 0, whichever is greater. To do this, you could use the following instruction:

\[
\text{CHARGE} \leftarrow 0.15 \times \max(0, \text{BALDUE})
\]
FINDING THE SMALLER OF TWO NUMBERS

The result of the minimum \( \text{min} \) function is the smaller of the two arguments.

EXAMPLES:

\[
\begin{align*}
& A+5 \\
& B+6 \\
& \text{A, B} \\
& 5 \\
& (B \times B) \text{L A A} \\
& 25 \\
& C+1 \ 4 \ 7 \ 9 \\
& D+3 \ 2 \ 8 \ 7 \\
& \text{C, D} \\
& 1 \ 2 \ 7 \ 7
\end{align*}
\]

Problems: Using the Maximum and Minimum Functions

1. Find the largest dollar expenditure for the following gasoline purchases:
   a. 16.8 gal at 57.9 cents per gal
   b. 13.5 gal at 60.9 cents per gal
   c. 15.6 gal at 62.9 cents per gal

2. For the following purchases, find the smallest quantity of nuts received:
   a. 71 cents for walnuts at 33 cents per lb
   b. 53 cents for cashews at 27 cents per lb
   c. 64 cents for pecans at 29 cents per lb

Suggested Solutions

Problem 1:

\[
(16.8 \times .579) \Gamma (13.5 \times .609) \Gamma 15.6 \times .629
\]

9.8124

Problem 2:

\[
(71 \div 33) \text{L} (53 \div 27) \text{L} 64 \div 29
\]

1.963
FINDING THE INDEX OF A VALUE IN A VECTOR

When you want to find out if a value is an element in a vector, and if it is, which element it is, you use the index of function \( \text{index} \). The index of function gives you the position (index) of the first occurrence in the left argument of the values in the right argument. If a value in the right argument is not in the left argument, the result is 1 plus the length of the left argument.

EXAMPLES:

\[
\begin{align*}
4 & \quad \text{Index of the first occurrence.} \\
3 & \quad \text{Index generator function.} \\
8 & \quad \text{Value does not occur in the left argument; the result is 1 plus the length of the left argument.}
\end{align*}
\]

GENERATING A RANDOM SEQUENCE OF NUMBERS

In Chapter 3, you used the roll function \( \text{roll} \) with one argument to generate one random number. But by using the deal function \( \text{deal} \) with two arguments, you can generate a random sequence of numbers without generating the same number twice. That is, the deal function generates the number of random numbers specified by the left argument from 1 through the value specified by the right argument. The random numbers are selected so that no two numbers are the same. Therefore, the left argument cannot be greater than the right argument. If you specify the left argument equal to the right argument, you get all the numbers from 1 through the number specified by the right argument, in random order.
SELECTING CERTAIN ELEMENTS (COMPRESSING) FROM A VECTOR OR MATRIX

You can use the compress function / to select certain elements from a vector or matrix. The left argument must be a vector of all 1's and 0's or an expression that results in such a vector. When you select elements from a vector the number of elements in each argument must be the same; the corresponding elements of the right argument are retained for each 1 in the left argument.

EXAMPLES:

\[
\begin{align*}
V &:= 1 2 3 4 5 6 7 8 \\
&:= 1 0 1 1 0 1 1 1/V \\
&:= 0 0 0 0 0 0 0 0/V \\
&:= 1 3 4 6 7 8 \\
\end{align*}
\]

Result is an empty vector.

\[
\begin{align*}
A &:= 1 0 0 0 0 0 1/V \\
&:= 1 0 1 0/'ABC'
\end{align*}
\]

\[
\begin{align*}
AC &:= 1 0 1 0/'ABCD'
\end{align*}
\]
When selecting elements from a matrix, you must select and omit entire rows or columns. To do this, you must specify the coordinate (rows or columns) to be acted on by using an index value [1]. The index value is 1 if the first coordinate (rows) will be acted on and 2 if the second coordinate (columns) will be acted on.

EXAMPLES:

```
B<3 4 12
  B
  1 2 3 4
  5 6 7 8
  9 10 11 12
```

Remember, the left argument must contain a 1 for each item to be selected and a 0 for each item to be omitted.

```
0 1 0/113B
  5 6 7 8
  1 0 1 0/123B
  1 3
  5 7
  9 11
```

The first coordinate (rows) is specified.

```
1 0 1 0/1B
  1 3
  5 7
  9 11
```

The second coordinate (columns) is specified.

```
```n
If no index entry is specified, the last coordinate (columns) is acted on.

EXPANDING A VECTOR OR MATRIX

You can use the expand \ function to insert blanks or zeros in a vector or matrix. The left argument must be a vector of all 1's or 0's or an expression that results in such a vector. The number of 1's in the left argument must be equal to the number of elements in the right argument. The 0's in the left argument indicate where the blanks or zeros will be inserted; blanks are inserted in a character vector or matrix and zeros are inserted in a numeric vector or matrix.

EXAMPLES:

```
1 1 0 1 0 1\1 2 3 4
1 2 0 3 0 4
1 1 0 1 0 1\'ABCD' 
```

AB C D
When you expand a matrix, entire rows or columns of blanks or zeros are inserted. As when using the compress function, you can specify the coordinate (rows or columns) to be acted on by using an index value \([1]\). The index value is 1 if the first coordinate (rows) is to be acted on and 2 if the second coordinate (columns) is to be acted on. If no index entry is specified, the last coordinate (columns) is acted on.

**EXAMPLES:**

The left argument must contain a 1 for each row or column being acted on. That is, the number of ones in the left argument must be equal to the coordinate being acted on (for example, the number of rows or columns).

- **Insert columns.**
  - \(B \leftarrow 2 \rho \ 14\)
  - \(B\):
    - 1 2 3 4
    - 1 2 3 4
    - 1 1 0 1 3
- **Insert rows.**
  - \(C \leftarrow 2 \rho 'ABC\) 9'
  - \(C\):
    - 1 0 2
    - 0 3
  - \(A B\): 0 1
  - \(C D\): 0

If no index entry is specified, the last coordinate (columns) is acted on.

**Problems: Using the Compress and Expand Functions**

1. Define a vector called ACCTS containing these five accounts: 56 103 100 13 0. Select those with balances of $100 or more.

2. Define the matrix DATA: 3 3 9. Then insert a row in DATA, with the values 20, 21, and 22, after the first row.

**Possible Solutions**

*Problem 1:*

\[
\text{ACCTS} \leftarrow 56 \ 103 \ 100 \ 13 \ 0
\]

\[
\text{(ACCTS} \geq 100) \ \text{/ACCTS
}\]

\[
103 \ 100
\]
Problem 2:

\[
\begin{align*}
\text{DATA} &+ 3 \ 3 \ 9 \\
\text{DATA} &+ 1 \ 0 \ 1 \ 1 \ \text{[1]} \\
1 & \ 2 \ 3 \\
4 & \ 5 \ 6 \\
7 & \ 8 \ 9 \\
\text{DATA} &+ 1 \ 0 \ 1 \ 1 \ \text{[1]} \\
\text{DATA} &+ 2 \ 0 \ 21 \ 22 \\
1 & \ 2 \ 3 \\
20 & \ 21 \ 22 \\
4 & \ 5 \ 6 \\
7 & \ 8 \ 9 \\
\end{align*}
\]

**JOINING TWO ITEMS TOGETHER**

You use the catenate function (, ) to join two vectors together to make a single vector by placing a comma between the left and right arguments. The number of elements in the resulting vector is the sum of the number of elements in the two vectors being joined (catenated).

**EXAMPLES:**

\[
\begin{align*}
A & + 1 \ 2 \ 3 \\
B & + 4 \ 5 \ 6 \\
\ A,B & \\
1 & \ 2 \ 3 \ 4 \ 5 \ 6 \\
\ B,A & \\
4 & \ 5 \ 6 \ 1 \ 2 \ 3 \\
C & + \text{`CAT' } \\
D & + \text{`EN'} \\
E & + \text{`ATION'} \\
C,D,E & \\
\text{CATENATION} \\
\end{align*}
\]

A vector must be either all numbers or all characters; therefore, you cannot catenate character data to numeric data.
You also use the catenate function to join two matrices together. To do this, you can use an index value [1] to specify which coordinate is to be extended (that is, whether the number of rows or the number of columns is to increase). The index value is 1 if the first coordinate (number of rows) is to be extended and 2 if the second coordinate (number of columns) is to be extended. When no coordinate is specified, the last coordinate (columns) is acted on.

**EXAMPLES:**

1. 

```
A 2 14
B 2 4+14
```

```apl
A+2 2p+14
B+2 2p4+14
```

```apl
A,:.B
```

1 2 5 6
3 4 7 8

You have just joined two columns to two existing columns (increased the number of columns).

2. 

```
A 2 14
B 2 4+14
```

```apl
A,:.B
```

1 2 5 6
3 4 7 8

A,:[1]B

When no coordinate is specified, the last coordinate (columns) is acted on.

3. 

```
A 2 14
B 2 4+14
```

```apl
A,:.B
```

1 2 5 6
3 4 7 8

A,:[1]B

1 2
3 4
5 6
7 8

In this case, you have joined two rows to two existing rows (increased the number of rows).

When you catenate two matrices, the arguments must conform—that is, the lengths of the columns (number of rows) must be the same if the columns are to be catenated and the length of the rows (number of columns) must be the same if the rows are being catenated.
EXAMPLES:

\[
\begin{align*}
A & = \begin{bmatrix} 2 & 4 \\ 4 & 4 \\ 4 & 4 \\ 6 & 6 \\ 6 & 6 \\ 6 & 6 \\ \end{bmatrix} \\
C & = \begin{bmatrix} 2 & 6 \\ 6 & 6 \\ 6 & 6 \\ \end{bmatrix}
\end{align*}
\]

LENGTH ERROR

The length error was caused because the row coordinate was specified when A and C have rows of different lengths.

\[
A, [1]C
\]

Note that the matrices can be joined along the column coordinate, since the lengths of the columns are the same.

Building a Vector of Results Using Catenation

Suppose that as you work through a series of problems you want to accumulate the answers. One way to do this is to catenate each new result to a vector of results previously obtained. If the most recent result is in a variable called LATEST and all the former results are in a vector called RESULT, you could use the following instruction:

\[
RESULT \leftarrow RESULT, LATEST
\]
Note: The first time this instruction is executed, there is no value for RESULT. Therefore, before you use this instruction, you should enter the following instruction:

RESULT←1 0

This instruction gives RESULT an initial value (makes it an empty vector).

EXAMPLES:

LATEST←10+5

RESULT←RESULT,LATEST

RESULT does not have a value; therefore, it is not a variable and cannot be used in an instruction.

RESULT←1 0

RESULT

Give RESULT an initial value (empty vector).

RESULT←RESULT,LATEST

RESULT

Blank display.

RESULT←RESULT,LATEST

RESULT

Now RESULT can be used.

15

LATEST←15+10

RESULT←RESULT,LATEST

RESULT

15 25

Problem: Using the Catenate Function

Assign codes to variables as follows: A←'I', B←'T', C←'D', D←'R', E←'GH', F←'YO', G←', and H←'U'. Then see what message is displayed if you catenate the variables in the following sequence:

FHGCACGABGDAE
Possible Solution

A< 'I'
B< 'T'
C< 'O'
D< 'R'
E< 'GH'
F< 'YO'
G< ' ' 
H< 'U'
YOU DID IT RIGHT

FINDING THE LOGARITHM OF A NUMBER

You use the logarithm function to find the log of the right argument to the base specified by the left argument. The log of a number B to a base A is the power needed to raise A to the value B.

EXAMPLES:

\[ \begin{align*}
A &= 2 \\
B &= A \times 3 \\
B &= 8 \\
A \times B &= 16 \\
3 &= \text{The log of } B \text{ to the base } A
\end{align*} \]
Problem: Using the Logarithm Function

1. What is the logarithm of 256 to the base 2?
2. To what power must 10 be raised in order for it to equal 100000?

Possible Solutions

Problem 1:

\[ 2 \times 256 \]
8

Problem 2:

\[ 10 \times 100000 \]
5
It is often useful to have the sum (or the product, or the maximum, for example) of all the elements in a vector. APL has a simple procedure for applying the same function to all the elements of a vector collectively. This function is called reduction, because it reduces a numeric vector down to a single number that represents the sum, the product, or the maximum, for example. The reduction operator is /. The left argument is the function that is applied to all the elements in a vector; the vector is the right argument.

You may have noticed that the reduction operator and the compress function have the same symbol. However, you can tell the difference between the compress function and the reduction operator by the left argument. For the compress function, the left argument is a vector of 1's and 0's and for the reduction operator, the left argument is an APL built-in function.

**PLUS REDUCTION**

**EXAMPLES:**

```
A+1 2 3 4 5
+/A
15
1+2+3+4+5 ← Adding all the elements of A together is the same as +/-A.
```

**Using Plus Reduction To Find the Average**

The reduction operator is useful for finding the average of the elements in a vector. Suppose vector X is as follows:

```
X+2 4 3 3 2.5 2
```
The following expression could be used to find the average of the elements in X:

\[ \text{AVG} \left( \sum X \right) / \text{length of } X \]

\[ \text{AVG} \]

2.75

Now let's analyze the previous expression.

1. We find the number of elements in X (the length of X):

   \[ \text{length of } X \]

   6

2. Then we calculate the sum of the elements in X:

   \[ \sum X \]

   16.5

3. Now we can find the average by dividing 16.5 by 6:

   \[ \text{AVG} \left( 16.5 / 6 \right) \]

   \[ \text{AVG} \]

   2.75
Problems: Using Plus Reduction

1. Using reduction, find the average amount that a certain family spends each week on food. The weekly grocery bills for November were $31.05, $29.78, $25.44, and $35.98.

2. Temperatures of a laboratory solution were recorded over a 12-hour period:

<table>
<thead>
<tr>
<th>Time</th>
<th>Temperature</th>
</tr>
</thead>
<tbody>
<tr>
<td>6 AM</td>
<td>75.8°</td>
</tr>
<tr>
<td>7 AM</td>
<td>71.9°</td>
</tr>
<tr>
<td>8 AM</td>
<td>77.0°</td>
</tr>
<tr>
<td>9 AM</td>
<td>80.3°</td>
</tr>
<tr>
<td>10 AM</td>
<td>85.1°</td>
</tr>
<tr>
<td>11 AM</td>
<td>82.2°</td>
</tr>
<tr>
<td>12 Noon</td>
<td>83.2°</td>
</tr>
<tr>
<td>1 PM</td>
<td>84.9°</td>
</tr>
<tr>
<td>2 PM</td>
<td>85.3°</td>
</tr>
<tr>
<td>3 PM</td>
<td>85.0°</td>
</tr>
<tr>
<td>4 PM</td>
<td>82.5°</td>
</tr>
<tr>
<td>5 PM</td>
<td>80.9°</td>
</tr>
<tr>
<td>6 PM</td>
<td>78.4°</td>
</tr>
</tbody>
</table>

Find the average temperature.

Possible Solutions

**Problem 1:**

\[
\text{BILLS} = 31.05 \text{, } 29.78 \text{, } 25.44 \text{, } 35.98
\]

\[
\text{AVG} = \frac{\text{SUM} \text{BILLS}}{\text{COUNT} \text{BILLS}}
\]

\[
\text{AVG} \approx 30.563
\]

**Problem 2:**

\[
\text{TEMP} = 75.8 \text{, } 71.9 \text{, } 77.0 \text{, } 80.3 \text{, } 85.1 \text{, } 82.2 \text{, } 83.2 \text{, } 84.9 \text{, } 85.3 \text{, } 85.0 \text{, } 82.5 \text{, } 80.9 \text{, } 78.4
\]

\[
\text{AVG} = \frac{\text{SUM} \text{TEMP}}{\text{COUNT} \text{TEMP}}
\]

\[
\text{AVG} \approx 80.962
\]
Using Plus Reduction to Sum the Products of Two Vectors

Suppose that PRICE is a variable that contains the price list for various items sold by a store, and Q1 and Q2 are two vectors indicating the quantity of these items ordered by two customers. Then the total bill for customer 1 is the sum of the product of PRICE times Q1, and the total bill for customer 2 is the sum of the product of PRICE times Q2.

EXAMPLES:

<table>
<thead>
<tr>
<th>PRICE</th>
<th>0.66</th>
<th>1.40</th>
<th>27.10</th>
<th>2.39</th>
<th>14.00</th>
<th>7.60</th>
<th>8.45</th>
<th>2.80</th>
</tr>
</thead>
<tbody>
<tr>
<td>Q1</td>
<td>0</td>
<td>2</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Q2</td>
<td>12</td>
<td>7</td>
<td>0</td>
<td>5</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>10</td>
</tr>
</tbody>
</table>

\[ \text{+/Q1 \times \text{PRICE}} \]
56.59
\[ \text{+/Q2 \times \text{PRICE}} \]
57.67

MINUS REDUCTION (ALTERNATING SUM)

EXAMPLES:

\[ \text{A + 3 2 1 4} \]
\[ \text{-A} \]
\[ -2 \]
\[ 3 - 2 - 1 - 4 \]

\[ -/A \]
\[ \text{-2} \]

3 - 2 - 1 - 4

\[ \text{is the same as this expression.} \]

The following illustration shows why the answer is -2.

Direction of processing is from right to left.

3 - 2 - 1 - 4

First operation (subtract 4 from 1; the result is -3).

2 - 3

Second operation (subtract -3 from 2; the result is 5).

3 - 5

Third operation (subtract 5 from 3; the final result is -2).

-2

Result.
MAXIMUM REDUCTION: FINDING THE LARGEST VALUE IN A VECTOR

To select the largest single element in a vector, you can reduce the vector using the maximum \( \max \) function.

EXAMPLES:

\[
\text{BALDUE} = 62, 15, 127, 4, 42, 18, 65 \quad \text{Amount owed by all the customers of a store.}
\]

\[
\max / \text{BALDUE} = 127 \quad \text{Largest amount owed.}
\]

MINIMUM REDUCTION: FINDING THE SMALLEST VALUE IN A VECTOR

To select the smallest single element in a vector, you can reduce the vector using the minimum \( \min \) function.

EXAMPLES:

\[
\text{NUMBER} = 1, 6, 4, 7 \quad 9
\]

\[
\min / \text{NUMBER} = 9
\]
OR REDUCTION: CHECKING FOR A SPECIFIC VALUE IN A VECTOR

Suppose you want to know whether a certain value exists in a long vector. You could use Or reduction (v) to find the answer.

EXAMPLES:

Generate a vector of 50 random numbers.

\[ \text{NUMBERS} \backslash= 50 \? 1.0 \]

\[ \text{v} / \text{NUMBERS} = 8 \]

The result of \( \text{NUMBERS} \backslash= 8 \) is a vector consisting of a 0 for each element of \( \text{NUMBERS} \) that does not equal 8 and a 1 for any element that does equal 8.

When the vector (result of \( \text{NUMBERS} \backslash= 8 \)) is reduced (the Or function is placed between each element), the result is 1 if at least one of the elements was 1.

A displayed result of 1 indicates that the value 8 was in \( \text{NUMBERS} \) and a 0 indicates that it was not.

AND REDUCTION: CHECKING FOR ALL VALUES IN TWO VECTORS BEING EQUAL

You can use And reduction (\( \wedge \)) to determine whether corresponding elements of two vectors are equal.

EXAMPLES:

Two vectors that have the same number of elements.

\[ \text{KEY} \backslash= 1.01 \ 1.763 \ 1.888 \ 1.2346 \ 1.2272 \]

\[ \text{LOCK} \backslash= 1.01 \ 1.763 \ 1.898 \ 1.2346 \ 1.2272 \]

\[ \wedge / \text{KEY} = \text{LOCK} \]

At least one of the elements of \( \text{KEY} \) does not match the corresponding element of \( \text{LOCK} \).
Chapter 6. Using the Built-in Functions

This chapter contains a summary of the things you can do with the APL built-in functions. Some of the functions have already been discussed in the previous chapters and all of the functions are described in the *IBM 5110 APL Reference Manual, SA21-9303*. Also, there is an example included for each function; you should enter these examples on your 5110 to see how these functions work.

*Note*: Many of these functions provide special computational capabilities.

**NOW LET'S LOOK AT THE THINGS YOU CAN DO**

<table>

## Things You Can Do

**APL Functions That Require Two Arguments (see Chapter 4 for more information)**

The result from the following six functions is 1 if the relationship specified by the APL function is true; otherwise the result is 0.

<table>
<thead>
<tr>
<th>Determine whether two values are equal</th>
<th>Equal to</th>
</tr>
</thead>
<tbody>
<tr>
<td>33 = 33</td>
<td><a href="#">Equal to</a></td>
</tr>
<tr>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Determine whether the left argument is greater than the right argument</th>
<th>Greater than</th>
</tr>
</thead>
<tbody>
<tr>
<td>16 &gt; 7</td>
<td><a href="#">Greater than</a></td>
</tr>
<tr>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Determine whether the left argument is less than the right argument</th>
<th>Less than</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 &lt; 4</td>
<td><a href="#">Less than</a></td>
</tr>
<tr>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Determine whether the left argument is greater than or equal to the right argument</th>
<th>Greater than or equal to</th>

</thead>
<tbody>
<tr>
<td>6 ≤ 6 9</td>
<td><a href="#">Less than or equal to</a></td>
</tr>
<tr>
<td>1 1</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Determine whether two values are not equal</th>
<th>Not equal to</th>
</tr>
</thead>
<tbody>
<tr>
<td>7 ≠ 7 7</td>
<td><a href="#">Not equal to</a></td>
</tr>
<tr>
<td>1 0</td>
<td></td>
</tr>
</tbody>
</table>
### Things You Can Do

The following two logical functions are usually used to check the results from relational operations. Logical functions can use only 1's and 0's as arguments. The result is 1 when the condition being checked for is met; otherwise, the result is 0.

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>And</td>
<td>( \wedge ) 0</td>

</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Minimum</th>
</tr>
</thead>
<tbody>
<tr>
<td>5 ( \geq ) 4</td>
</tr>
<tr>
<td>4</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Index of a given value in a vector</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 9 8 7 6 5 7 3 2 1</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Deal</th>
</tr>
</thead>
<tbody>
<tr>
<td>2 3 1 3 ( \oplus ) 6</td>
</tr>
</tbody>
</table>
### Things You Can Do

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compress (select certain elements from) a vector or matrix</td>
<td>( \backslash ) /</td>
</tr>
<tr>
<td>Expand a vector or matrix</td>
<td>( \backslash ) /</td>
</tr>
<tr>
<td>Join two arguments together</td>
<td>; ;</td>
</tr>
<tr>
<td>Find the log of a number</td>
<td>( \circ ) ( \div )</td>
</tr>
<tr>
<td>Change the sign of a number</td>
<td>- +</td>
</tr>
<tr>
<td>Find the sign of a number</td>
<td>+ x</td>
</tr>
<tr>
<td>Find the reciprocal of a number</td>
<td>= x</td>
</tr>
</tbody>
</table>

### Examples

<table>
<thead>
<tr>
<th>Input</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>( 2 5 ) ( 1 0 0 1/2 \ 3 4 5 )</td>
<td>Selects the elements that correspond to the ones in the left argument</td>
</tr>
<tr>
<td>( 2 ) ( 0 \ 3 ) ( 0 \ 4 \ 0 \ 5 ) ( 0 )</td>
<td>Inserts elements according to the zeros in the left argument</td>
</tr>

### APL Functions In Addition To The Ones Already Discussed In Previous Chapters (see the IBM 5110 APL Reference Manual, SA21-9303, for more information)

- **Negation**
  
  \( -3 -4 \)

- **Signum**

  \( x \) \( -2 \) \( 0 \) \( 2 \)

  The result is ‘1 for a negative number, 0 for 0, and 1 for a positive number.

- **Reciprocal**

  \( \div 3 \)

  \( 0.33333 \)
Things You Can Do

• Raise $e$ (2.71828) to a power

\[
\begin{align*}
&1 \cdot e^{1.3} \\
&2.7183 \times 20.086
\end{align*}
\]

• Find the log of a number to the base $e$

\[
\begin{align*}
&\log_e 2.7183 \times 20.086 \\
&1 \cdot 3
\end{align*}
\]

• Multiply a number by pi

(3.14159)

\[
\begin{align*}
&\pi \cdot 1 \cdot 3 \\
&3.1416 \times 9.4248
\end{align*}
\]

• Find the product of all whole numbers between 1 and a specified number

\[
\begin{align*}
&1! \\
&24 \leftarrow The result is the same as 1\times2\times3\times4.
\end{align*}
\]

• Change a 1 to a 0 or a 0 to a 1

Logical not

\[
\begin{align*}
&\neg 1 \cdot 0 \\
&0 \cdot 1
\end{align*}
\]

• Determine whether at least one of two conditions is false

Nand

\[
\begin{align*}
&1 \times 1 \cdot 0 \\
&0 \cdot 1 \leftarrow The result is 1 when at least one argument is 0; otherwise the result is 0.
\end{align*}
\]

• Determine whether two conditions are false

Nor

\[
\begin{align*}
&1 \circ 1 \cdot 0 \\
&0 \cdot 0 \leftarrow The result is 1 when both arguments are 0; otherwise the result is 0.
\end{align*}
\]

Things You Can Do

- Find the remainder left over from a divide operation

\[ \text{Residue (remainder)} \]

\[ 3 \div 2 = 1 \text{ remainder } 1 \]

2 is the remainder of 8 divided by 3.

- Find the values for the trigonometric functions of an angle

\[ \text{Circular} \]

\[ \tan(45^\circ) = 1 \]

The result is the tangent of 45° (\( \pi \div 4 \) radians).

- Find the number of combinations of a number taking so many at a time

\[ \text{Binomial (combination)} \]

\[ \binom{4}{2} = 6 \]

Four items taken two at a time can make six different combinations.

- Find out if a certain value (left argument) exists in a vector or matrix

\[ \text{Membership} \]

\[ 'ABC' \in 'BANANA' \]

The result is 1 if the value in the left argument exists in the right argument; otherwise the result is 0.

- Express a value in another number system

\[ \text{Decode (base value)} \]

\[ 5415 \rightarrow 24 \ 60 \ 60 \ 1 \ 30 \ 15 \]

Expresses 1 hour 30 minutes 15 seconds in all seconds.

- Represent a value in a specified number system

\[ \text{Encode (representation)} \]

\[ 1 \ 30 \ 15 \rightarrow 24 \ 60 \ 60 \ 5415 \]

Represents 5415 seconds in hours, minutes, and seconds.
Things You Can Do

- Solve one or more sets of linear equations with coefficient matrices

\[
\begin{bmatrix}
2 & 6 & 9 & 8 & 12 & 2 & 0 & 3 & 5 & 1 & 2
\end{bmatrix}
\]

- Take a certain number of elements from a vector or matrix

\[
\begin{bmatrix}
1 & 2 & 3
\end{bmatrix}
\begin{bmatrix}
1 & 1 & 1 & 2 & 3 & 4 & 5
\end{bmatrix}
\Rightarrow
\begin{bmatrix}
1 & 2 & 3
\end{bmatrix}
\begin{bmatrix}
3 & 1 & 4
\end{bmatrix}
\]

These three elements were taken from the vector.

- Drop a certain number of elements from a vector or matrix

\[
\begin{bmatrix}
4 & 5
\end{bmatrix}
\begin{bmatrix}
1 & 1 & 1 & 2 & 3 & 4 & 5
\end{bmatrix}
\Rightarrow
\begin{bmatrix}
1 & 1 & 1 & 2 & 3 & 4 & 5
\end{bmatrix}
\begin{bmatrix}
5 & 4
\end{bmatrix}
\]

The result is the elements remaining after the specified number of elements have been dropped.

- Join two arguments together by forming an array with an additional dimension

\[
\begin{bmatrix}
1 & 2 & 3 & 4 & 5
\end{bmatrix}
\begin{bmatrix}
6 & 7 & 8 & 9 & 0
\end{bmatrix}
\Rightarrow
\begin{bmatrix}
1 & 2 & 3 & 4 & 5
\end{bmatrix}
\begin{bmatrix}
6 & 7 & 8 & 9 & 0
\end{bmatrix}
\]

Two vectors are joined to form a matrix.

- Rotate the elements in a vector or matrix as specified by the left argument

\[
\begin{bmatrix}
2 & 0 & 1 & 2 & 3 & 4 & 5
\end{bmatrix}
\begin{bmatrix}
3 & 4 & 5 & 1 & 2
\end{bmatrix}
\Rightarrow
\begin{bmatrix}
2 & 0 & 1 & 2 & 3 & 4 & 5
\end{bmatrix}
\begin{bmatrix}
3 & 4 & 5 & 1 & 2
\end{bmatrix}
\]

Rotates the vector two positions.
Things You Can Do

- Create data arrangements with at least one dimension (a data arrangement with two dimensions has both rows and columns)

  Each number in the left argument is called a coordinate—this N-rank array has three coordinates.

  Last coordinate is the columns.

  Next to the last coordinate specifies rows.

  Leftmost coordinate is the planes.

  Planes

  You can index elements within N-rank arrays by putting a semicolon between coordinates.

- Interchange coordinates (such as rows and columns of a matrix) of an array

  When used with one argument, this function reverses the coordinates.

  Note: This function could also be used with a left argument that specifies how the coordinates are to be interchanged.

Chapter 7. Function Definition

WHAT IS FUNCTION DEFINITION?

Although APL has many built-in functions, there will be times when you want a special function to solve a problem. APL allows you to define your own functions (called user-defined functions) and store them for repeated use.

HOW IS A FUNCTION DEFINED?

You use existing APL functions to create a new user-defined function. The new function consists of:

- A function header containing the name of the function and other information (the types of function headers are discussed later in this chapter).
- An expression or series of expressions, called statements, which define the operation(s) to be performed.

When executing APL expressions, the IBM 5110 is in execution mode; however, before a new function can be defined, the mode must be changed to function definition mode. The \( \triangledown \) (del) symbol is used to change the 5110 from one mode to another. For example, to change from execution mode to function definition mode, a \( \triangledown \) is entered as the first character in the function header; then after the function is defined, another \( \triangledown \) is entered to close the function definition and change the mode back to execution mode. Once the 5110 is back in execution mode, you can execute your user-defined function.

Now, to show how a function is defined, let's create a function to find the hypotenuse of a right triangle. The expression used for this could be written as \((A^2 + B^2)^{0.5}\), where we square the lengths of the two sides A and B and then take the square root of their sum, which is the length of the hypotenuse. The function must have a name by which it can be identified, so let's name this function HYP. Now enter the opening \( \triangledown \) (to place the 5110 in function definition mode) and the function header, as follows:

\[
\triangledown \text{HYP} \leftarrow A \quad \text{HYP} \quad B \rightarrow \quad \text{Function header.}
\]

APL responds with the number of the first statement (expression) to be entered.
As each statement is entered, the next statement number is displayed.
Now enter the remainder of the function as follows:

```
HP←((A*2)+(B*2))* .5
```

Expression

Closing V - Changes mode back to execution mode.

Notice that the names in the function header (other than the function name itself) are all used in the body of the function. In particular, notice how the result variable name, HP, is assigned the final result by a statement in the function.

The display screen will now look like this:

```
VHP←A HYP B
[1] HP←((A*2)+(B*2))* .5
[2] V
```

**Note:** If you make a mistake when entering this function, see *What To Do If You Make a Mistake When Defining Your Function* later in this chapter.

When you entered the closing V, the function HYP was stored in your active workspace, so you can use it just like any other APL function with two arguments.

**EXAMPLE:**

```
3  HYP  4
   Lengths of the two sides.
5
   Length of the hypotenuse.
X←6
Y←8
X HYP Y

10
R←3 6
L←4 8
R HYP L
   Like other APL functions, the arguments can be in different forms.
```

Whenever you want to use HYP, just enter its name with the arguments you want. The symbol for the calculation of the hypotenuse of a right triangle is HYP, just as the symbol for addition is +.
A function can have only one instruction, like HYP, or it can contain many instructions.

**EXAMPLE:**

```
\(*\) \(VHPL + A\) \(HYPL B\)  
[1] \(A2 + A*2\)  
[4] \(HP + S* . 5V\)  
5  \(\rightarrow\) \(HYPL 4\)  
```

The function HYP could also have been defined like this.

Note that the closing \(\) can also be on the same line as the last instruction. Same result as HYP.

**Problems: Using Function Definition**

1. Define a function that displays the sum of any two numbers. Then use the function.

2. Define a function that displays the area of any rectangle. Then use the function.

**Possible Solutions**

**Problem 1:**

```
\(*\) \(V5 + M\) \(SUM N\)  
[1] \(S + M + NV\)  
6 \(SUM 3\)  
9  
```

**Problem 2:**

```
\(*\) \(VA + LENGTH\) \(AREA WIDTH\)  
[1] \(A + LENGTH \times WIDTH\)  
[2] \(\rightarrow\) \(AREA 5\)  
20  
```

**TESTING YOUR FUNCTION BEFORE USING IT**

Once you define your function, you should always try using it with data that will give you a known result. For example, suppose that in the function HYP you used the following expression by mistake:

\[
((A \times 2) + (B \times 2)) \times .5 
\]

Should have been *
You would get an answer, but it would not be the right answer for the hypotenuse of a right triangle.

When you test your function, one of the following will occur:

- The 5110 will display the result you expect.
- The 5110 will display an error message.
- The 5110 will display a result, but not the result you expect.
- Nothing will happen.

If the 5110 Displays the Result You Expect

Great! Your function works.

*Note:* Even though your function worked one time, you may want to test it some more to make sure it will work for each application you intend to use it for.

If the 5110 Displays an Error Message

You can use the *IBM 5110 APL Reference Manual, SA21-9303*, to find out what the error message means and what you must do to correct it.

*Note:* An error condition will cause the execution of your function to stop; see Chapter 8 for more information on what to do when your function stops executing.

If the 5110 Displays a Result Other Than the One You Expect, or If Nothing Happens

In either of these cases, you have two alternatives:

- Display the entire function and check it for errors. *Displaying the Entire Function* is discussed later in this chapter.
- Use the trace and stop features (discussed next) to help find the problem.

*Note:* When a user-defined function is used and nothing happens (that is, neither result nor the cursor appears on the display screen) or a result is repeated continuously, the function is probably *looping*. In this case, press the ATTN key to stop (suspend) function execution. Chapter 8 contains information on what to do when your function stops.
HOW TO USE THE TRACE AND STOP FEATURES

Trace TΔ

The trace feature allows you to watch the execution of your function, statement by statement. That is, the final result calculated for each statement traced is displayed. You can either trace all of the statements or just certain statements in a function. To use the trace feature, enter TΔ, the function name, →, and the statement numbers to be traced. For example:

TΔEXAMPLE←1 2 3 4 5 6

The statement numbers to be traced
The name of the function to be traced

The previous statement could also be entered as follows:

TΔEXAMPLE←6

Generates a vector of numbers from 1 to 6

Stop SΔ

The stop feature allows you to stop the execution of your function just before a specified statement is executed. That is, function execution is temporarily suspended (suspended functions will be discussed in greater detail in Chapter 8). After function execution has stopped, the 5110 displays the number of the next statement to be executed. To use the stop feature, enter SΔ, the function name, →, and the numbers of the statements before which function execution is to stop. For example:

SΔEXAMPLE←3 6

The specified statement numbers
The name of the function

After function execution has stopped, you can start it again by entering →LLC. LLC (line counter) is a system variable that contains the next statement number to be executed; see Chapter 9 for more information about system variables, and the IBM 5110 APL Reference Manual, SA21-9303, for a complete description of the LLC system variable.
Now let's use trace and stop to find a problem in a function.

EXAMPLES:

\[
\text{VHP}+A \quad \text{HYPX} \quad B
\]

1. 'THE HYPOTENUSE IS'  
2. \( A^2 + A \times 2 \)  
3. \( B^2 + B \times 2 \)  
4. \( S + A^2 + B^2 \)  
5. \( HP + S \times 5 \)

\[
\text{THE HYPOTENUSE IS} \\
12.5
\]

Defines a function that calculates the hypotenuse of a right triangle.

This function has an error in it.

Tests the function using data for which the correct result is known. The result should be 5.

Using the trace feature to find the problem

The 5110 responds with the function name, statement number, and the result of the statement being traced.

The correct result was obtained in each statement except statement 5; therefore, statement 5 probably contains the error.

To turn off the trace feature, use 10 as the statement to be traced.

Using the stop feature to find the problem

The 5110 responds with the function name and the next statement number to be executed.

When the function is stopped, you can enter the variables to see if they contain the expected values.

Continue execution by entering \( \text{[L]C} \).

Execution stops at the next statement specified for the stop feature.

All the variables contained the correct values; therefore, statement 5 must be in error.

To turn off the stop feature, use 10 as the statement to be stopped at.

Note: How to correct an error in a function is discussed next.
WHAT TO DO IF YOU MAKE A MISTAKE WHEN DEFINING YOUR FUNCTION

If you make a mistake when defining your function, you can correct it by editing the function. When editing a function, you can do the following:

- Display the entire function.
- Add one or more statements at the end of the function.
- Replace statements.
- Insert one or more statements.
- Delete a statement from the function.
- Display a specific statement or from a specific statement to the end of the function.
- Modify a single statement.

If you notice your mistake as you are defining your function, you can correct it without reopening the function definition (the 5110 is already in function definition mode). However, if the function definition is closed, you must first reopen it. To do this, you must enter the `\` followed only by the function name. If you enter the complete function header, you will get an error message.

Now, let’s define a function to use in doing some function editing. Enter the following:

```
\VSTAT X
[1] N+\rho X
[2] (+/X)/N
[3] \L/X
[4] \G/V
```

This function calculates the average, smallest, and largest number in a vector of numbers. Notice that this function does not have a result variable in the function header; however, it will still display the results. The reason for having a result variable in your function will be discussed later.
Displaying the Entire Function

To display a function, you enter [1] immediately after any statement number or as shown in the following example.

EXAMPLE:

This instruction opens, displays, and closes the function definition.

\[
\forall \text{STAT}[:X]
\]

[1] \(N+\rho X\)
[3] \(L/X\)
[4] \(f/X\)

\[
\forall \text{STAT } 2 : ? 1
\]

4
1
9
Adding One or More Statements at the End of the Function

To add statements to a function, you open the function definition and the number of the first available line is displayed. Then you can enter the statements you want to add.

EXAMPLE:

The 5110 displays the number of the first available line.

\[ \forall \text{STAT} \]
\[ \text{[5]} \ (\sqrt{X}) - L/X \]

Open the function.

Add this statement to find the range of the numbers in the vector. The \( \forall \) closes the function (you are only adding one line).

\[ \forall \text{STAT} \]
\[ \text{[4]} \text{[3]} \text{[2]} \text{[1]} \]
\[ \sqrt{X} \quad N := \rho X \quad (+/X) \div N \quad L/X \]

Display the function.

Displayed function.

\[ \text{STAT} 9 \ 2 \ 1 \]

Try the function.
Replacing Statements within a Function

To replace statements, the statement number to be replaced must be enclosed in brackets [ ] followed by the new statement.

EXAMPLE:

```
\[V\text{STAT} \{\] \\
\[V\text{STAT} \{X\] \\
\[1\] \(N+\rho X\) \\
\[2\] \((+/X)/N\) \\
\[3\] \(L/X\) \\
\[4\] \(\Gamma/X\) \\
\[5\] \((\Gamma/X)-L/X\) \\
\[V\]

\[V\text{STAT}\{\] \\
\[V\text{STAT} \{X\] \\
\[1\] \(N+\rho X\) \\
\[2\] \((+/X)/\rho X\) \\
\[6\] \[2\] \((+/X)/\rho X\)
```

This instruction opens and displays the function.

Displayed function.

The 5110 displays the number of the first available line.

Notice that you can specify another statement number by enclosing it in brackets.

Now, replace statement 2 with this statement for finding the average. The \(\Gamma\) closes the function.

In this example, you could also use the scroll down key \(\downarrow\) and scroll up key \(\uparrow\) to place statement 2 on the input line 1. Then statement 2 can be corrected; however, you must make sure that statement 3 does not appear on line 0 before you press EXECUTE.

```
\[V\text{STAT}\{\] \\
\[V\text{STAT} \{X\] \\
\[1\] \(N+\rho X\) \\
\[2\] \((+/X)/\rho X\) \\
\[3\] \(L/X\) \\
\[4\] \(\Gamma/X\) \\
\[5\] \((\Gamma/X)-L/X\) \\
\[V\]

\[V\text{STAT}\{\] \\
\[V\text{STAT} \{X\] \\
\[1\] \(N+\rho X\) \\
\[2\] \((+/X)/\rho X\) \\
\[3\] \(L/X\) \\
\[4\] \(\Gamma/X\) \\
\[5\] \((\Gamma/X)-L/X\) \\
\[V\]

\text{STAT} 9 1 2
```

4
1
9
8
Inserting One or More Statements in a Function

To insert statements in a function, you must use a decimal statement number that is between the numbers of the statements where you want to insert the new statement. For example, to insert a statement between statements 1 and 2, you could use the statement number 1.5 or any decimal number between 1 and 2.

EXAMPLE:

```
V STAT
[6] [1.5] X
[1.6] \n
Open the function.

The 5110 displays the number of the first blank line.

Insert a statement between statements 1 and 2; the inserted statement displays the vector of numbers.

If you do not enter \, the 5110 responds with another decimal statement number.

Enter the closing \.

V STAT[0] \n V STAT X
[1] N=ρX
[2] X
[3] (+/X)÷ρX
[6] (Γ/X)-L/X
\n
Display the function.

Notice that the 5110 has renumbered the statement numbers.

STAT 9 2 1
9 2 1
4
1
9
8
```
Deleting a Statement from a Function

To delete a statement from a function, you enter \([\Delta n]\), where \(n\) is the number of the statement you want to delete.

**EXAMPLE:**

```
\(\n\) STAT X
\(\) [1] \(N+\rho X\)
\(\) [2] \(X\)
\(\) [3] \((+X)/\rho X\)
\(\) [4] \(L/X\)
\(\) [5] \(\Gamma /X\)
\(\) [6] \((\Gamma /X)-L/X\)
```

Open and display the function.

```
\(\n\) Displayed function.
```

```
\(\n\) The 5110 displays the next available statement number.
```

```
\(\n\) Remove statement 4; you no longer need to know the smallest number.
```

*Note:* The closing \(\) must not be entered on the same line as \([\Delta n]\); you must enter it on another line or an error will occur.

```
\(\n\) Display the modified function.
```

```
\(\n\) Displayed function—the original line 4 was deleted and the statements were renumbered.
```

```
\(\n\) STAT 2 9 1
```

2 9 1
4
9
8

You can also delete a statement by displaying the statement on input line 1, pressing the ATTN key (to blank the entire expression), and then pressing EXECUTE. Displaying a specific statement is discussed next.
Displaying a Specific Statement or from a Specific Statement to the End of a Function

You have already seen how to display the entire function; you can also display only one statement or each statement from a certain statement to the end of the function. To display one statement, you enter \([n\text{O}]\), where \(n\) is the statement number you want to display. To display each statement from a certain statement to the end of the function, you enter \([\text{On}]\), where each statement from statement \(n\) to the end of the function is to be displayed.

**EXAMPLE:**

\[\forall \text{STATE}[3]\forall \text{--- Display statement 3.}\]
\([3]\) \((+/X)÷ρX\)

\[\forall \text{STATE}[4]\forall \text{--- Display each statement from statement 4 to the end of the function.}\]
\([4]\) \(Γ/X\)
\([5]\) \((f/X)−L/X\)

Modifying a Single Statement

You can correct keying errors in a statement of a function the same way you correct keying errors made during entering of instructions in execution mode. That is, the same procedures for inserting, deleting, or replacing characters are used. To correct keying errors in function definition mode, you must currently be entering the statement in error or you must display the statement you want to correct.
EXAMPLE:

```apln
VSTAT[2] X
VSTAT[2] N
V
```

- Open the function and display statement 2.
- Enter an N to replace the X in the displayed line.
  (You now want to know the number of elements in the vector.)
- The 5110 responds with [3]; now enter the closing `V`.

```apln
VSTAT[?][?]
V STAT X
V STAT X

[1] N+\rho X
[2] N
[3] (+/X)÷\rho X
[4] \Gamma/X
```

The original function header is replaced with this function header.

- Display the function.

```apln
V
```

- N has replaced the X.

```apln
\text{Note: Do not be concerned at this time if the error message SI DAMAGE is displayed; this error message and a suggested user response is described in the IBM 5110 APL Reference Manual, SA21-9303.}
```

```apln
VSTAT[?][?]
DEFN ERROR VSTAT
```

You cannot display the function STAT because the function no longer has that name.

Editing the Function Header

You can edit the function header the same way you would edit any other statement in the function. To do this, you specify statement 0 as the statement to be edited.

EXAMPLE:

```apln
VSTAT[0] VSTAT X V
VSTAT[?][?]
VSTAT[?][?]
VSTAT[?][?]
V STAT X

[1] N+\rho X
[2] N
[3] (+/X)÷\rho X
[4] \Gamma/X
```

- The original function header is replaced with this function header.
- Display the function.

```apln
\text{Note: Do not be concerned at this time if the error message SI DAMAGE is displayed; this error message and a suggested user response is described in the IBM 5110 APL Reference Manual, SA21-9303.}
```
A Faster Way to Add, Replace or Insert One Statement in a Function

If your function is closed and you have only one statement to add, replace, or insert, you can do it using only one instruction. For example, the following instruction opens, changes, and closes the function definition:

\[
\text{VSTAT1 E33 (+/X) N4}
\]

Opens the STAT1 function.

Specifies that statement 3 is to be edited.

Replaces the existing statement 3.

Closes the STAT1 function.
EXAMPLE:

\[ V \text{STAT1} \]

Display the \text{STAT1} function.

\[ \text{STAT1} X \]

[1] \( N \times pX \)
[2] \( N \)
[3] \( (+/X) \div pX \)
[4] \( \Gamma/X \)
[5] \( (\Gamma/X) - \big/ X \)

\[ V \text{STAT1} \]

Add a statement to the function.

\[ \text{STAT1} 2 9 1 \]

Now try the function.

3
4
9
8

THIS STATEMENT WAS ADDED

\[ \text{STAT1} \]

Replace a statement.

\[ (+/X) \div N \]

Insert a statement.

\[ L/X \]

Display the modified function.

\[ \text{STAT1} X \]

[1] \( N \times pX \)
[2] \( N \)
[3] \( (+/X) \div N \)
[4] \( L/X \)
[5] \( \Gamma/X \)
[6] \( (\Gamma/X) - \big/ X \)
[7] \( \text{THIS STATEMENT WAS ADDED} \)

\[ \text{STAT1} 2 9 1 \]

3
4
1
9
8

THIS STATEMENT WAS ADDED
TYPES OF FUNCTION HEADERS

Like the APL built-in functions, you can have user-defined functions with one or two arguments. You can also have user-defined functions without any arguments. The number of arguments required by a function is defined in the function header. For example:

\[ \text{result} + \text{argument1} \quad \text{functionname} \quad \text{argument2} \\\n\quad \text{This function requires two arguments.} \]

\[ \text{result} + \text{functionname} \quad \text{argument} \\\n\quad \text{This function requires one argument.} \]

\[ \text{result} + \text{functionname} \\\n\quad \text{This function requires no argument.} \]

When a function is executed, the value used for an argument is assigned to the variable name that appears as the argument in the function header. This variable is then used in the function. For example, you might have the following function:

\[ \text{result} + \text{a} \quad \text{divide} \quad \text{b} \]

\[ \text{result} + \text{a} \quad \text{divide} \quad \text{b} \]

If you enter 10 \text{divide} 2, the value 10 is assigned to \text{a} and the value 2 is assigned to \text{b}. Now when the statement \text{a} \text{divide} \text{b} is executed, the result is 5.

Note: For some user-defined functions (as with some built-in functions), it is important that you enter the arguments in the proper order. For example, if you enter 2 \text{divide} 10, the answer would be 0.2 instead of 5.

When you define a function with one argument, the argument must be to the right of the function name; otherwise, the argument will be treated as the function name, and vice versa.
EXAMPLES:

\[
\text{VR} \leftarrow \text{A AREA1 B}
\]

Two arguments—this function finds the area of a rectangle.

\[
\text{R} \leftarrow \text{A} \times \text{B}
\]

\[
\text{12 AREA1 12}
\]

\[
\text{VR} \leftarrow \text{SQRT X}
\]

One argument—this function finds the square root of a number.

\[
\text{R} \leftarrow \text{X} \times \text{.5V}
\]

\[
\text{A} \leftarrow 1 4 9 16 25 36
\]

\[
\text{SQRT A}
\]

The argument can be a vector.

\[
\text{VR} \leftarrow \text{DICE}
\]

No argument—this function simulates the roll of two dice.

\[
\text{R} \leftarrow \text{?6 6}
\]

\[
\text{DICE}
\]

\[
1 5
\]

\[
\text{DICE}
\]

\[
3 4
\]

The results can be any pair of numbers between 1 and 6.

WHY HAVE A RESULT VARIABLE?

So far in our discussion of user-defined functions, we have usually defined functions with a result variable. A result variable is a variable in which the result of a function is temporarily stored for use in an APL expression. When your function has a result variable, it is said to have an explicit result. Without an explicit result, your function cannot be used in an APL expression.

The following function has a result variable; therefore, it has an explicit result.

\[
\text{RESULT} \leftarrow \text{QTY ITEMX COST}
\]

\[
\text{RESULT} \leftarrow \text{COST} \div \text{QTY V}
\]

The result variable must appear in both the function header and the body of the function (it must be included in the statement where the final result is determined).
EXAMPLES:

\[
VQTY \text{ ITEM} \quad \text{COST}
\]

Define a function without an explicit result.

\[
[1] \text{COST} \leftarrow VQTY
\]

\[
10 \text{ ITEM} \quad .60
\]

\[
0.06
\]

\[
\text{STORE} + 10 \text{ ITEM} \quad .60
\]

The result of the function cannot be used in APL expressions.

\[
0.06
\]

\[
\text{VALUE ERROR}
\]

\[
\text{STORE} + 10 \text{ ITEM} \quad .60
\]

\[
0.06
\]

\[
\text{VALUE ERROR}
\]

\[
10 + 10 \text{ ITEM} \quad .60
\]

\[
0.06
\]

\[
\text{VALUE RESULT} \leftarrow Q \text{ ITEM} \quad C
\]

Define a function with an explicit result.

\[
[1] \text{RESULT} \leftarrow C / QV
\]

\[
10 \text{ ITEM} \quad .60
\]

\[
0.06
\]

\[
\text{STORE} + 10 \text{ ITEM} \quad .60
\]

The result of the function can now be used in an APL expression.

\[
0.06
\]

\[
\text{STORE}
\]

\[
10 + 10 \text{ ITEM} \quad .60
\]

\[
10.06
\]

Remember, if you plan to use the function you are defining in an APL expression, you must provide a result variable.

LOCAL AND GLOBAL NAMES

A name appearing in a user-defined function can be either local or global. A global name has the same value during the execution of a function as it has outside of the function. A local name has a value that is available only while the function is active. Any name appearing in the function header (except the function name) is a local name. So far we have seen that a function header can contain a result variable and arguments. Because these variable names are contained in the function header, they are local to the function. But other names can also be made local to the function if they are placed in the function header following the right argument (if any) with a semicolon preceding each name. For example, the function header \( \nu \text{ LOOP R;I;J} \) makes the right argument R and the variables I and J local to the function. Now to see how local and global names work, let's use some.
EXAMPLES:

Define a function without any local names.

1. Define a function without any local names.

2. Define a function with all local names.

3. Notice how the names are made local to the function.

4. Execute LOCAL, then enter the variable names to see what values they represent.

5. Define a function using both local (GA and GB) and global (GC) names.

6. Local names that are the same as existing global names.

7. Global name.

8. Notice that outside the function, the existing global values (previously established by the function GLOBAL) are used. The new values (6 and 7) existed only during the execution of the function.

9. Because this variable name is not local to the function, the global value was changed.
Now, you are probably wondering why you should make variable names local to a function. Following are some reasons for using local variables:

- Let’s assume you have defined a function named COUNT that uses a variable named X. At some later time, you assign the result of an important calculation to a global variable named X. Now if you execute COUNT, the following conditions can occur:

  1. If X was made local to COUNT, the global value of X is not changed.
  2. If X was not local to COUNT, the global value of X (the results of your important calculation) is changed.

- You can conserve space in your active workspace by not storing the values for variables you do not use outside a function.

BRANCHING, LABELS, AND LOOPING

Branching and Labels

Statements in a user-defined function are normally executed in the order indicated by the statement numbers, and execution terminates at the end of the last statement in the sequence. However, this normal order of execution can be modified by branching (transferring to another point in the sequence). Branching is indicated by a right arrow \( \rightarrow \) followed by a label that specifies the statement to be branched to.

For example, the expression \( \rightarrow \text{START} \) means branch to a statement labeled START. When a label is assigned to a statement, the label is followed by a colon and must precede the statement. The colon separates the label from the statement:

\[
\begin{align*}
[2] & \quad \text{START}: N & \leftarrow & N + 1 \\
[5] & \rightarrow \text{START}
\end{align*}
\]

In the previous illustration, the label START is assigned to the second statement in the function. In this case, START has a value of 2; however, if the function is edited and the statement is no longer the second statement in the function, START will automatically be given the value of the new statement number. Now as the function executes, when statement 5 is executed, a branch is taken to the statement labeled START. If the same label appears more than once in a function, any branches taken to that label always branch to the first statement with the label.
Labels are local to a function; that is, they can be used only within that function. Following are some rules that apply exclusively to the use of labels:

- They must not appear in the function header.
- You cannot assign values to them.

There are two types of branch statements you can use—unconditional branches and conditional branches:

- **Unconditional branches** are branches that are taken each time the branch statement is executed. You have already seen an example of an unconditional branch, \([5] \rightarrow \text{START}\), where the branch to the statement labeled START is taken each time statement 5 is executed. Another common use of an unconditional branch is \(\rightarrow 0\), which causes the execution of the function to be terminated.

- **Conditional branches** are branches that are taken depending upon some condition that exists at the time the branch statement is executed. Conditional branches are used, for example, to branch to a statement if a condition is true and to otherwise continue with the next statement (fall through). This type of branch can be entered like this:

\[ \rightarrow (\text{CONDITION}) / N \]

The branch to statement N is taken if the condition is true; otherwise the next statement is executed. For example, APL executes the branch statement \(\rightarrow (I \geq N) / \text{START}\) as follows:

1. First, the condition \((I \geq N)\) is evaluated; the result is 1 if the condition is true and 0 if the condition is false.
2. The result of step 1 is then used as the left argument for the compress (/) function:
   a. If the result of step 1 was 1, \(\text{START}\) is selected from the right argument and a branch to the statement labeled \(\text{START}\) is taken.
   b. If the result of step 1 was 0, nothing is selected from the right argument (an empty vector is the result). A branch to an empty vector means execute the next statement in sequence (fall through).
In the following example, you will use two variations of a function to determine the sum of each number from 1 to the value of the argument (each function will use a different method of branching).

EXAMPLES:

\[ \text{VS+SUM2 } N \]

[1] S = 0
[2] I = 1
[3] CHECK: \rightarrow (I \geq N) \rightarrow 0 \quad \text{Branch to 0 (terminate the function) or fall through to the next statement.}
[4] S = S + I
[5] I = I + 1
[6] \rightarrow \text{CHECK}\quad \text{Unconditional branch to CHECK.}

\text{SUM2 } 5

\[ \text{VS+SUM3 } N \]

[1] S = 0
[2] I = 0
[4] I = I + 1
[5] \rightarrow (I \leq N) \rightarrow \text{CHECK}\quad \text{Branch to CHECK or fall through.}

\text{SUM3 } 5
Looping

A repeated segment of a function is called a loop; when you have a loop in your program, you must provide a way to get out of the loop.

EXAMPLE:

\[ \text{\texttt{VLOOP}} \quad \text{This function executes a continuous loop.} \]
\[ [1] \quad \text{I=0} \]
\[ [2] \quad \text{LABEL: 'THIS PROGRAM CONTAINS A LOOP'} \]
\[ [3] \quad \text{I=I+1} \]
\[ [4] \quad \text{A LABELV} \]

\text{LOOPS}

\text{THIS PROGRAM CONTAINS A LOOP}
\text{THIS PROGRAM CONTAINS A LOOP}
\text{THIS PROGRAM CONTAINS A LOOP}
\text{THIS PROGRAM CONTAINS A LOOP}
\text{THIS PROGRAM CONTAINS A LOOP}
\text{THIS PROGRAM CONTAINS A LOOP}
\text{THIS PROGRAM CONTAINS A LOOP}
\text{THIS PROGRAM CONTAINS A LOOP}

Note: To stop execution of LOOP, press the ATTN key.

\text{LOOP[3]} \rightarrow \quad \text{The name of the function and the statement number where execution stopped is displayed.}

\text{VLOOP[4]}+(I\neq3)/\text{LABELV} \quad \text{Provide a way to get out of the loop.}

\text{VLOOP[4]} \rightarrow \quad \text{Display the function.}

\[ [1] \quad \text{I=0} \]
\[ [2] \quad \text{LABEL: 'THIS PROGRAM CONTAINS A LOOP'} \]
\[ [3] \quad \text{I=I+1} \]
\[ [4] \quad \text{+(I\neq3)/LABEL} \]

\text{VLOOP}

\text{THIS PROGRAM CONTAINS A LOOP}
\text{THIS PROGRAM CONTAINS A LOOP}
\text{THIS PROGRAM CONTAINS A LOOP}

The loop is executed three times.
HOW TO ENTER DATA DURING FUNCTION EXECUTION

So far you have defined functions for which you have supplied the data for the function as arguments. This method of supplying data limits you to two input arguments, and you must be familiar with the function so that you can enter the required arguments in the correct order. However, you can also define user-defined functions that display requests for input data as the function executes. This type of function allows you to input any amount of data; and you can also define your function so that it specifies what type of data is to be entered. To do this, you use the \( \square \) (quad) or \( \square!' \) (quad quote) symbols in your function to request input from the keyboard. When a \( \square \) is encountered in a function, execution stops and \( \square: \) is displayed to indicate that the system is waiting for numeric or character input (character data must be enclosed in single quotes) from the keyboard. When a \( \square!' \) is encountered in a function, execution stops, the cursor appears, and the system waits for input from the keyboard; but in this case, everything on the input line from position 1 to the cursor or the last character entered (whichever is the farthest on the input line) is treated as character input, even though you do not use enclosing single quotes when you enter the data.

EXAMPLE:

Enter the following user-defined function to determine the final score of a baseball game:

```
VBASEBALL
[1] 'ENTER THE NAME OF THE VISITING TEAM'
[2] VISIT<\square>
[3] 'ENTER THEIR SCORE BY INNING'
[4] VSCORE<\square>'
[6] HOME<\square>
[7] 'ENTER THEIR SCORE BY INNING'
[8] HSCORE<\square>'
[9] 'THE FINAL SCORE WAS:'
[10] VISIT
[12] HOME
[13] +/HSCORE<\square>'
```

The score by inning was:

- **REDS**: 0 1 0 2 0 3 2 5 0
- **BLUES**: 0 0 0 2 3 1 3 0 0

The input from the keyboard will replace the \( \square \) or \( \square!' \) and be assigned to the variables.
EXAMPLE (continued)

Now execute the function:

```
BASEBALL
ENTER THE NAME OF THE VISITING TEAM
REDS

ENTER THEIR SCORE BY INNING
0: 0 1 0 2 0 3 2 5 0
ENTER THE NAME OF THE HOME TEAM
BLUES
ENTER THEIR SCORE BY INNING
0: 0 0 0 2 3 1 3 0 0
THE FINAL SCORE WAS:
REDS 13
BLUES 9
```

Notice how the messages identify the type of keyboard input required.

This character data is not enclosed in single quotes because it was requested by a ` in the function.

This is not character data because it was requested by ` and is not enclosed in single quotes.

*Note:* A ` indicates that the keyboard input is requested by ` in the function; no ` : (blank line) indicates that the keyboard input is requested by ` in the function.

When you are using interactive functions, there may be times when you need to escape from a request for input. Normally, pressing the ATTN key causes the execution of your function to stop; however, pressing the ATTN key during a request for input does not stop the function (the function continues to wait for input to be entered). Therefore, APL provides a way to escape from input requests. To escape from a ` input request, you enter `, which causes execution of your function to be terminated.

To escape from a ` input request, you must enter the ` (OUT) character. You enter this character by holding the CMD key and pressing the ` key once, and then pressing the EXECUTE key. This will cause the execution of your function to stop. What you can do next when your function stops is discussed next, in Chapter 8.
EXAMPLE:

```
BASEBALL
ENTER THE NAME OF THE VISITING TEAM
REDS
ENTER THEIR SCORE BY INNING []:
  
BASEBALL
ENTER THE NAME OF THE VISITING TEAM
```

Let's use the BASEBALL function to show how to escape from input requests.

Entering → in response to a [] input request causes the execution of the function to be terminated.

Try escaping from a [] by entering →. Your entry was treated as a character, and used as the visiting team's name.

```
ENTER THEIR SCORE BY INNING []:
  1 1 1 1 1 1 1 1
ENTER THE NAME OF THE HOME TEAM []:
```

Enter some numbers so that the next [] input request will be displayed.

```
INTERRUPT
BASEBALL[6] HOME+[]
```

Entering the [] character (holding CMD and pressing the key once) causes the execution of the function to stop.
Chapter 8. What You Can Do When Your Function Stops

The execution of your user-defined function will stop when:

- The ATTN key is pressed.
- The stop feature is used.
- An error is encountered in the function.
- A \[U\] character (the CMD key held and the \[+\] key pressed once) is entered for a \[!\] input request.

A function that has stopped executing for one of the preceding reasons is called a suspended function. A suspended function is still active, since its execution can be resumed later.

Now let's look at what you can do when your function stops executing.

WHEN THE ATTENTION KEY IS PRESSED

When you press the ATTN key during the execution of your user-defined function, the function stops executing at the end of the statement currently being executed. In this case, the 5110 displays the function name and the next statement number to be executed.

After your function stops executing, you can do one of the following:

- Edit the function.
- Execute the function again.
- Execute another user-defined function.
- Execute system commands except for )SAVE, )COPY, and )PCOPY. The system commands are described in the IBM 5110 APL Reference Manual, SA21-9303.
- Terminate the function by entering \[+\].
Generally, after you have stopped your function by pressing the ATTN key, you will want to resume execution of the function at a later time. To do this, you enter →+0 LC. →LC is a system variable that contains the statement number of the next statement to be executed (see the IBM 5110 APL Reference Manual, SA21-9303 for a complete description of the →LC system variable).

Note: If you want to resume execution at a statement other than the one immediately following the last statement executed, enter −→n (where n is the statement number at which you want to resume execution).

EXAMPLES:

```
VSFUNCTION;COUNT
[1] COUNT+0
[2] LOOP: 'THIS FUNCTION CONTAINS A LOOP'
[3] COUNT+COUNT+1
[4] →LOOP
[5] 'THIS FUNCTION LOOPED'
[6] COUNT
[7] 'TIMES'
```

```
SFUNCT ION
THIS FUNCTION CONTAINS A LOOP
THIS FUNCTION CONTAINS A LOOP
THIS FUNCTION CONTAINS A LOOP
THIS FUNCTION CONTAINS A LOOP
THIS FUNCTION CONTAINS A LOOP
THIS FUNCTION CONTAINS A LOOP
THIS FUNCTION CONTAINS A LOOP
```

```
SFUNCT ION[3] →
```

```
VSFUNCTION[4];(COUNT<3)/LOOP
```

```
→0LC
```

Define a function with a continuous loop.

Press the ATTN key to stop execution of the function.

The function is suspended at the statement number shown in the [ ] on your display screen.

Edit the function so that it does not contain a continuous loop.

Resume execution of the function.
EXAMPLES—continued

THIS FUNCTION LOOPED
7 TIMES

The value shown here on your display screen is the number of times the function looped.

SFUNCTION
THIS FUNCTION CONTAINS A LOOP
THIS FUNCTION CONTAINS A LOOP
THIS FUNCTION CONTAINS A LOOP
THIS FUNCTION LOOPED
3 TIMES

Now execute the function again.

Note: When the shift key is held down and the ATTN key is pressed during the execution of an APL statement or expression (either within or outside a user-defined function), the execution of the statement or expression stops immediately. The message INTERRUPT, the statement being processed, and the caret (\^) that indicates where the statement was interrupted is displayed. You can use this method to interrupt statements that take a long time to execute. However, any results generated by the statement or expression before it was interrupted might not exist after the interrupt.

WHEN THE STOP FEATURE IS USED

You are already familiar with the stop feature, which was discussed in Chapter 7. When using the stop feature (as when using the ATTN key), you can do the following:

• Edit the function.
• Execute the function again.
• Execute another user-defined function.
• Execute system commands except for )SAVE, )COPY, and )PCOPY.
• Resume function execution by entering \[1] LC.
• Terminate the function by entering \[.\]
WHEN AN ERROR IS ENCOUNTERED IN THE FUNCTION

The reason the execution of your function stopped in this case, unlike the reasons in the other two cases, cannot be controlled by you. That is, the 5110 automatically stops the execution of your function and displays an error message when an error occurs in the function. The error messages and a suggested user’s response for each error are described in the IBM 5110 APL Reference Manual, SA21-9303.

Errors in a user-defined function are sometimes difficult to find and correct. The error message displayed indicates where the execution of the statement stopped, and why; but the reason the failure occurred at that point might have been because a mistake (either a keying error or an error in the solution to the problem) was made earlier in the statement or because a mistake was made in an even earlier statement in the function. Following are some hints to help you find errors in a statement or expression that is failing or giving the wrong results.

- Check the expression (statement) you entered for any keying errors.

- Analyze the execution of the expression from right to left. Remember, APL executes an expression from right to left with the expressions in parentheses resolved (right to left) as they are encountered.

- Use the shape \( \rho \) function to make sure the shapes of the arguments are what you expect. For example, suppose you have a function named CAT that catenates two vectors together to form one vector; however, one of the arguments you supplied was a matrix (this causes a LENGTH ERROR).

- Enter the names to check the values of the arguments to make sure they are what you expect (local variables in a suspended function can be displayed, since the function is still active).

- Break the expression down and execute it in smaller segments. The up \( \uparrow \) and down \( \downarrow \) arrows (scroll up and scroll down keys) make it easy for you to break the expression down; that is, you can execute the expression as APL does (from right to left with expressions in parentheses resolved as they are encountered). To do this, you enter the first operation performed by APL, for which the result will be displayed. Then press the down arrow three times and the up arrow once to remove the previous result from the display screen (so that it is not on the input line when the EXECUTE key is pressed again) and to place the instruction you just entered in a position for you to add more operations. Now you can add the next operation to the instruction, and the next, until the error in the instruction is found.
Display intermediate results from the expression using the □. This does not change the final result. For example:

```
3 \times 4 + 5 - 2
```

```
21
```

```
3 x [1+4]+[1+5]-2
```

```
3
```

```
?  
```

```
21
```

It is important that you maintain a history (either a printout on the printer or a handwritten copy) of what you did when you were trying to find the cause of an error. Then if you cannot find the error and you think the problem is caused by the 5110, this history will help your service representative determine where the problem is.

When a function has stopped because an error occurred, as when pressing the ATTN key or using the stop feature, you can do the following:

- Edit the function.
- Execute the function again.
- Execute another user-defined function.
- Execute system commands except for )SAVE, )COPY, and )PCOPY.
- Resume execution of the function by entering → □ LC.
- Terminate the function by entering → .

**WHEN A Ϟ CHARACTER IS ENTERED FOR A □ INPUT REQUEST**

In Chapter 7, you used the Ϟ character to escape from a □ input request and to stop function execution. In that case, the 5110 displayed the message INTERRUPT, the function name, and the statement that requested the input. After your function stops, you can do the same operations that you did when the function stopped for any other reason. However, in most cases, you will want to terminate the function by entering → .

**FINDING OUT WHAT FUNCTIONS ARE SUSPENDED**

The state indicator contains the function name and the number of the statement to be executed next for each suspended function. To display the state indicator, you enter )SI or )SINL. See the *IBM 5110 APL Reference Manual*, SA21-9303, for more information on the state indicator.
USING THE HOLD KEY TO STOP PROCESSING

We have already discussed the ways a user-defined function can be suspended. You can also stop the execution of a function by pressing the HOLD key once. In fact, this stops the entire system from processing any data. To resume processing after pressing the HOLD key, you must press the HOLD key again. The HOLD key is useful when the information on the display screen is changing rapidly; that is, you can stop processing, read the displayed information, and then resume processing.

EXAMPLES:

\[
\text{HOLDF} \quad \text{Define a function.}
\]

1. \( H := 0 \)
2. 'PRESS THE HOLD KEY TO STOP PROCESSING'
3. \( \text{LOOP}: H := H + 1 \)
4. \( H \)
5. \( \rightarrow (H \neq 25) / \text{LOOP} \)

Now press the HOLD key again to resume processing.
So far you have used only the 5110 active workspace. The active workspace is the part of the 5110's internal storage where the calculations are performed; it is also the place where the variables and user-defined functions are stored. When you set the 5110 POWER ON/OFF switch to OFF or press RESTART, the data in the active workspace is lost. However, before turning the power off or pressing RESTART, you can save the data in your active workspace by writing the contents of the active workspace on a tape cartridge or diskette. This media (tape or diskette) is like a library; that is, you can write the contents of your active workspace on the media (like placing a book on the library shelf) and, at a later time, put the information stored on the media back into the active workspace (like taking the book off the library shelf to use it again).

The library consists of one or more files (each file is like a book), and just as each book in the library has a name, each file that contains information on the media also can have a name (file identification).

The IBM 5110 system commands are your means of controlling the active workspace and storage media (library). Look at the labels above the alphanemic keyboard; you can enter these system command keywords by simply pressing the CMD key with the appropriate key below the label. The system command keywords can also be entered character by character. Notice that each system command begins with a ) symbol. There are some system commands that do not appear on the labels above the keyboard. All of the 5110 system commands are discussed in detail in the *IBM 5110 APL Reference Manual*, SA21-9303.

In the following example, you will see how some of the system commands work. First, a tape cartridge or diskette must be inserted into your system.

If you are using a tape cartridge:

1. Be sure the tape contains no data required for any further use.
2. Make sure that the SAFE switch (Figure 3) does not point to SAFE.
3. Insert the tape cartridge (Figure 4).
If you are using a diskette:

1. Be sure the diskette is initialized and contains no data required for any further use.

   Note: The IBM-supplied diskettes are initialized before they are sent to a customer.

2. Remove the diskette from the protective envelope (Figure 5).

3. Insert the diskette into diskette drive 1 (Figure 6).
Make sure the SAFE switch is in this position.

Figure 3. The SAFE Switch

Insert the tape cartridge as shown.

Figure 4. Inserting a Tape Cartridge
Figure 5. Removing the Diskette from the Protective Envelope

This label must be in the lower right corner as the diskette is inserted.

Figure 6. Inserting a Diskette in Diskette Drive 1
EXAMPLES:

Press RESTART on your 5110; all the data that was in the active workspace is now lost.

CLEAR WS → This message will be displayed when the 5110 is again ready for you to enter data.

Enter the following function and variable so that you can store them on the media for later use:

```
VAR EXAMPLE; NAME
[1] 'THIS FUNCTION COUNTS THE CHARACTERS IN YOUR NAME'
[2] 'NOW ENTER YOUR NAME'
[3] NAME+0
[4] 'THERE ARE'
[5] ρ; NAME
[6] 'CHARACTERS IN YOUR NAME'

VARIABLE+LET 'S SAVE THIS DATA'
```

Now try the function EXAMPLE to see if it works.

```
)FNS EXAMPLE
The )FNS system command displays user-defined function names in the active workspace.

)VARS VARIABLE
The )VARS system command displays the global variable names in the active workspace.
```

Before the storage media can be used, the files you want to use must be formatted.
The )MARK command formats files on the media. This command specifies:
- Size of the files to be formatted
- Number of files to format
- Starting file number
- Device. If you are using tape storage, specify 1 (tape drive 1). However, if you are using diskette storage, specify 2 (diskette drive 1) instead of tape drive 1. See the IBM 5110 APL Reference Manual for the default device used by the system if the device is not specified.

APL will respond with MARKED, number of the last file marked, and the size of the files. If the file you want to use has been marked before, you will get a message ALREADY MARKED. In this case, enter GO and press the EXECUTE key to reformat the tape files.

Note: If you enter the )MARK command by holding down the CMD key and pressing the key, the command is displayed as follows:

These characters identify the parameters required for the command and must be replaced with the required information.
KB stands for the size of the files to be formatted in K(1024) byte blocks; NF stands for the number of files to be marked; SF stands for the starting file number; DEV stands for the device number the media is on.

After the )MARK command is executed, the files are formatted in blocks of 1024 bytes. For example, the size of the files just formatted is sixteen 1024-byte blocks (or 16,384 total bytes). See the IBM 5110 APL User's Guide, SA21-9302, for information on what size to format files.
Now let's write the contents of the active workspace on the media. In the following examples, if you are using diskette storage, specify device 11 (diskette drive 1) instead of device 1 (tape drive 1). For example, device/file number 1001 should be 11001 for diskette.

```plaintext
)CONTINUE 1001 INFO
CONTINUED 1001 INFO
```

This becomes the name of the file on tape.

This specifies the device/file number (device 1, file 001) to which the contents of the active workspace are written.

```plaintext
)CLEAR
CLEAR WS
```

You do not have to turn the power off or press RESTART to clear all of the existing data out of the active workspace; you can use this system command.

The data in a stored workspace can be placed back into the active workspace.

```plaintext
)LOAD 1001 INFO
LOADED 1001 INFO
```

The stored workspace name (workspace ID).

The device/file number from which the stored workspace will be loaded.
Now the data that was stored on the media is in the active workspace once again.

The remaining system commands are described in the *IBM 5110 APL Reference Manual*. Try using these system commands to see how they work.

So far, you have learned how to write the entire contents of the active workspace on the media. However, you can also write one variable at a time to a file on the media. This data can then be read from the media at a later time in the same order as it was written to the media. For more information on how to do this, see the *IBM 5110 APL User's Guide*.

**WHAT ARE SYSTEM VARIABLES?**

System variables are variables within the active workspace that control the system. All system variables begin with the symbol and are set to an initial value by the 5110 in a clear workspace. See the *IBM 5110 APL Reference Manual* for a complete description of each system variable. In the following example, you will see how the value of some system variables can be changed and how this affects certain APL functions.

**EXAMPLES:**

The index origin system variable determines the index origin. The value of the system variable can be either 0 or 1, which means that the first element of a vector or array is indexed with a 0 or 1 depending upon what the system variable is set to. The APL functions \( ? \) and indexing \( \[ \] \) are affected by the system variable.

You can display the value of a system variable the same way you display the value of any variable.

The system variable is initially set to 1 by the system.

Results when the system variable is set to 1.
You can change the value of some system variables.

Notice how the results of these APL functions change when the ⍪IO system variable is changed.

These numbers can be in any order. Notice that the values start from 0.

The printing precision ⍪PP system variable determines the number of significant digits displayed.

The ⍪PP system variable is initially set to 5 by the system.

Five significant digits are displayed.

Now only two significant digits are displayed.

The comparison tolerance ⍪CT system variable determines how close two numbers must be when you are using the relational, floor, or ceiling functions.

The ⍪CT system variable is initially set to 1E-13 by the system.

These two values are not considered equal.

Now these two values are considered equal.

The workspace is clear and the system variables are once again set to their original values.
REMEMBER, APL IS A GOOD LANGUAGE TO EXPERIMENT WITH. THE MORE YOU EXPERIMENT, THE MORE YOU LEARN.
