FLOPPY DIAGNOSTIC LOADER/GENERATOR

1. PROGRAM TITLE

Floppy Diagnostic Loader/Generator (FDLG)

16 bit	06-225F01
32 bit	06-225F02

2. PURPOSE OF THE PROGRAM

The FDLG provides the facilities to load, build, and maintain Perkin-Elmer diagnostics on a floppy disc. The need for a paper tape diagnostic is eliminated. The Perkin-Elmer Floppy Media Disc (FMD) System is the only storage medium the FDLG supports.

3. MINIMUM HARDWARE REQUIRED

Processor: any 16 or 32-bit processor (7/32 with halfword mode, must be run in fullword mode)

Memory: 16-bit processor - 32KB
32-bit processor - 32KB

Console: Teletype on current loop interface; address X'02'.
or

- Carousel 30 or 35 on current loop interface; address X'02'.
or
- Carousel 300 on PASLA or PALM; address X'10,11'; full duplex; highest clock rate.
or
- Teletype on micro-I/O bus; address X'C0'.
or
- CRT on micro-I/O bus; address X'C0'.
or
- CRT on current loop interface; address X'02'.
or
- Carousel 30 or 35 on micro-I/O bus; address X'C0'.
or
- Carousel 300 on micro-I/O bus; address X'C0'.
or
- CRT on PASLA or PALM; address X'10,11'; full duplex; highest clock rate.

Display Device - display panel; address X'01'
or

- any ASCII console device as shown under console above.

List Device: Same as under "Console", plus high speed line printer; address X'62'.

Output Device: Floppy Media Disc System; address X'C1'.

Input Device: Floppy Media Disc System; address X'C1'.

4. SYSTEM REQUIREMENTS

- All I/O devices must have Perkin-Elmer standard addresses; if not, the following locations must be changed to reflect their actual addresses:

<u>LABEL</u>	<u>DEFAULT</u>	<u>DEVICE</u>
TTYAD	X'02'	Current Loop Device
LPAD	X'62'	Line Printer
MBUS	X'C0'	Micro-I/O Bus Console
FLPAD	X'C1'	Floppy Media Disc System

5. LOADING PROCEDURES

Insert any diskette of the supplied set in the desired drive and set up addresses X'78,79' as follows:

X'78' = Floppy Media Disc (FMD) System address

X'79' = YY, where YY = 86 for drive 0
96 for drive 1
A6 for drive 2
B6 for drive 3

Load the standard X'50' sequence shown below. The boot load program determines whether to load the 16-bit or 32-bit FDLG.

50 SEQUENCE

<u>LOCATION</u>	<u>CONTENTS</u>
X'30'	X'0000'
X'32'	X'0000'
X'34'	X'0000'
X'36'	X'0500'
X'50'	X'D500'
X'52	X'00CF'
X'54'	X'4300'
X'56'	X'0080'

Execute the X'50' sequence and the processor will stop with X'FFFF' in the display (or 'LOAD OK' printed on the micro-I/O bus console), a successful load is indicated. (The bootloader program loaded by the autoload retries until successful loading is accomplished; nominal successful loading time is less than 5 seconds). The FDLG loader segment may be restarted at any time by addressing X'6000' for both 16-bit processors and 32-bit processors. To execute the generator segment, address location START+4 and execute. The following is printed on the console device:

FDLG GENERATOR R01

*

NOTE

The loader segment normally communicates only with the display or the system console.

The generator segment uses the halfword labeled DEVTYPE to specify console type and it must be set up before executing the generator segment. Both bytes in the halfword must be set up as follows:

<u>DEVTYPE</u>	<u>USE</u>
X'0101'	CRT on PASLA or PALM
X'0202'	Current loop device
X'0404'	Carousel on PASLA or PALM
X'0505'	Micro-I/O bus device

Any value in DEVTYPE other than those shown is illegal and is interpreted as X'0202'.

6. OPERATOR COMMAND INFORMATION

6.1 COMMAND/OPTION INPUT STRUCTURE

An asterisk (*), output to the console device, indicates that the program is awaiting operator input. All options must be typed in from the console, followed by a space and the desired arguments separated by commas. A carriage return (CR) is issued to terminate every command option input. An invalid command/option or value causes a (?) followed by a carriage return (CR), line feed (LF), and an asterisk (*) to occur. If an error is made during entry of the option, the hash mark (#) can be input to delete the entire line, causing a carriage return (CR), line feed (LF), and an asterisk (*) to be output; or, the left arrow (\leftarrow) can be input to delete the previous character or a string of characters can be deleted by inputting a (\leftarrow) left arrow for each character to be deleted; the same is applicable to the DELETE character.

6.1.1 Delimiters And Field Termination

Either a space or comma may be used as a field delimiter. Any non-hexadecimal character input in any field (except the program name field) terminates that field; any field in excess of the maximum size allowed causes command rejection.

6.2 OPERATOR COMMANDS

The generator segment of the FDLG uses the following commands:

LIMITS	CREATE	DUPLICATE	INITIALIZE
FIND	UPDATE	SEQNUM	

NOTE

The program examines each command for its first character only.

6.2.1 INITIALIZE

This command prepares a formatted diskette for FDLG use. It initializes the directory, writes the boot loader program to sectors 5 and 6, and finds output medium capacity. A diskette must be loaded, ready, and NOT write-protected.

Format: INITIALIZE

Example: *I(CR)
 EOJ
 *

6.2.2 LIMITS

This command specifies the low and high boundaries of the memory image to be written to the diskette by the CREATE or UPDATE command. Memory limits depend only on the processor type (16 or 32-bit) and available memory. The software supports a full 24 bit address.

Format: LIMITS LLLLLL,HHHHHH(CR)
 LLLLLL = low memory limits to be transferred.
 HHHHHH = high memory limits to be transferred.

Example: *L A00,27C5(CR)

NOTE

Six-digit input is only valid for 32-bit processors; 16-bit processors use four-digit input.

6.2.3 SEQNUM

This command assigns a three digit sequence number, a three digit 06-number, the program revision level and a 30-character, free-form, program description. The sequence number used for each program should be unique; if it is not unique, an error message is printed on the console when the CREATE or DUPLICATE command is executed.

Format: SEQNUM SSS,PPP,RR [.]R ,NNNN.....(CR)
 SSS = sequence number
 PPP = 06 number
 RR [.]R = revision level, followed by an optional extension field indicating that the program has been patched to correct a problem with the stated revision level. The extension number corresponds to the number of change page packages incorporated. When the program is revised, all patches are programmed in and the extension field reverts to zero (a zero extension field is NOT printed when the LIST function is used).

NOTE

Not all change page packages are incorporated as they may not be applicable to all supported processors.

NNN = program description, up to 30 characters.

Example: S 03A,156,00,F01 MEMORY TEST PART 1(CR)

6.2.4 CREATE

This command outputs a memory image to the output device using the parameters entered with LIMITS and SEQNUM.

Format: CREATE (CR)

Example: *C
*EOJ
*

6.2.5 DUPLICATE

This command duplicates the program string specified from current input program (defined by FIND command) to the termination sequence number or EOV; the string is appended to the program(s) on the output device, and the termination sequence number is copied.

NOTE

If any deleted programs exist on the input drive (from using the UPDATE function), they are eliminated by the DUPLICATE function when they are copied to the output device.

Format: DUPLICATE NNN (CR)

NNN = sequence number

EXAMPLE: *D 403
EOJ

*D
EOJ

6.2.6 FIND

This command will search the specified volume for the specified sequence number and make that sequence number "current".

Format: FIND X,NNN (CR)

X = I or O, specifying input (I) or output (O) volume.

NNN = sequence number

Example: *F I,4C
EOJ
*

NOTE: Sequence number 000 is reserved for EOV.

6.2.7 UPDATE

This command deletes the specified sequence number from the diskette and CREATES a new program using the LIMITS and SEQNUM parameters previously entered.

Format: UPDATE XXX(CR)
 XXX = sequence number to be deleted.

Example: *U 124(CR)
 EOJ
 *

7. OPERATING PROCEDURES

This section describes the loader and generator operations.

7.1 LOADER PROCEDURES

Boot load the program as described in Section 5; or if already resident in memory, execute the program at X'6000' for both the 16-bit version and the 32-bit version. The processor then halts and the display contains X'FFFF'. Enter the program's sequence number (nonzero) to be loaded into the switch register/display and depress run. The FDLG reads the display and attempts to load the requested program. If the display contains X'FF', it indicates a successful load. After five retries, an error code is displayed. See Section 8 for an explanation of the error codes. If the switch register/display was set to zero, the FDLG will list the program definition block for each program on the diskette. The program assumes that the user wants a hard copy when he lists the contents of the media. To this end, the program searches for I/O device presence and availability in this order:

1. Line Printer
2. Micro-I/O bus console
3. Current loop interface
4. PASLA/PALM

If the device is present and it has correct status, it will list the media in the above priority.

NOTE

If the processor has no display (e.g. Model 5/16), all reference to the display is replaced by the Micro-I/O bus console. All entry is via the console keyboard and all display is in ASCII. See Section 8.1 for Micro-bus console messages.

7.2 GENERATOR PROCEDURES

Generator Procedures are as follows:

7.2.1 Device Assignments

Input/Output device selection is semiautomatic; input is whatever drive is specified in bits 2 and 3 of location X'79' (auto-load parameter) and the output drive is the other drive in the 0-1 or 2-3 even/odd pair. For example, if the boot drive is 1, input is set to 1 and output is set to 0; if the boot drive is 2, input is set to 2 and output is set to 3.

NOTE

The FDLG writes ONLY to the specified output drive; therefore, this drive must not be write protected.

7.2.2 Medium Initialization

Medium initialization of the output diskette must be done before the FDLG can use a diskette.

7.2.3 CREATE

This function finds the last directory entry (EOV) and adds a program in memory to the end of the directory. To create a program on a diskette follow these steps:

1. Load memory with the program to be put on the output diskette.
2. Place an initialized diskette in the output drive, without write protect.

NOTE

When building new media, the first two programs written to the diskette MUST be the 16 and/or 32-bit FDLG, for boot load purposes. Duplicating the first two programs from any FDLG diskette in the set supplied or by creating the FDLG twice in succession (with two unique sequence numbers) on an initialized diskette accomplishes this.

3. Boot load the FDLG from the input drive. Address X'6004' for both the 16-bit version and the 32-bit version and execute. The title (FDLG) is printed, followed by a prompt.

NOTE

The generator segment uses "DEVTYP" to determine which I/O device to use as a console; "DEVTYP" must be set up according to Section 5.

4. Enter the LIMITS option.
5. Enter the SEQNUM option.
6. Enter the CREATE command; the program is written to the output diskette and verified.
7. To add another program, load it into memory, start the generator at X'6004', and go to Step 4.

7.2.4 DUPLICATION

To duplicate an entire diskette:

1. Boot load the FDLG from the input diskette and/or start the generator segment at X'6004'.
2. Use the FIND command to position the current program pointer for the input diskette to the desired sequence number.
3. Initialize the output diskette.
4. Issue the DUPLICATE command, with no termination sequence number. This command tells the FDLG to duplicate to EOF.

NOTE

The normal duplication mode is to load the input program into memory and to write it to the output diskette. This mode is only deviated from when the LIMITS of the program being copied exceed 64KB and a 16-bit processor is being used; or when the LIMITS would overwrite the resident FDLG; or memory below X'A00' for 32-bit processors, or below X'2D0' for 16-bit processors. In this special mode, the program is read and copied one, 128-byte sector at a time. The time required to duplicate a program is measureably longer and the amount of head loading and unloading is extremely noticeable.

5. To copy a section of a diskette, position the input diskette (using FIND) and issue the DUPLICATE command specifying a termination sequence number. The input diskette is copied from the current position (including the current program) to the termination sequence number (including the termination sequence number).

7.2.5 UPDATE

To UPDATE a program to a later revision or to replace it entirely, follow these steps:

1. Load memory with the program to be put on the output diskette.
2. Boot load the FDLG and/or restart the generator segment at X'6004'.
3. Input the LIMITS option.
4. Input the SEQNUM option.
5. Issue the UPDATE command, specifying a sequence number. The corresponding program is deleted and the new memory resident program is created on the output diskette.

NOTE

If the specified sequence number does not exist, the command is rejected; a question mark and prompt are output.

8. MESSAGES

8.1 LOADER MESSAGES

The loader segment messages are:

<u>Display Data</u>	<u>ASCII Message</u>	<u>Meaning</u>
FFFF	FDLG LOADER R01	Successful load
00FF	EOJ	Job completed
EEEE	EOV	Program not found
3333	I/O ERROR ON LOAD	Bad status on load
5555	ATTEMPT TO OVER- LOAD FDLG	-
1111	EOV NOT FOUND	Read complete direct- ory and program or EOV not found.

8.2 GENERATOR MESSAGES

Generator segment messages are:

1. VERIFY ERROR - I/O error while verifying program just added to output diskette.
2. LOW>HIGH ERROR - low limits greater than high limits on input with LIMITS or when read from program definition block during any other function.
3. DISKETTE FULL - room does not exist on output diskette to fit a program with present parameters; a shorter program may fit.
4. DIRECTORY FULL - directory at maximum capacity (127 entries).
5. DEFECTIVE MEDIA - output medium has more than two bad tracks and cannot be used.
6. ILLEGAL INSTRUCTION - an illegal instruction has occurred. Refer to the appropriate user manual to determine where the address of the illegal instruction is stored.
7. MACHINE MALFUNCTION - a machine malfunction interrupt has occurred.
8. READ ERROR - status error on input drive.
9. DIRECTORY READ ERROR ON DRIVE X - read failed after five retry attempts. (X = drive number)
10. WRITE ERROR ON OUTPUT DRIVE - status error on output drive.
11. ERROR ON DIRECTORY UPDATE - directory update status failure.
12. FDLG GENERATOR R01 - program title, printed when generator segment is started.
13. SEQUENCE NUMBER EXISTS ON OUTPUT MEDIA - attempt to CREATE or DUPLICATE a non-unique sequence number.

9. FDLG STRUCTURE

9.1 DIRECTORY STRUCTURE

The directory is divided into four, 128-byte blocks, with thirty-two, 4-byte entries per block. The first two bytes in each entry correspond to the hexadecimal sequence number associated with the program and the second two bytes point to the Program

Definition Block (PDB) associated with that program. The PDB always precedes the memory image of the program and it contains the sequence number, 06- part number, revision number, program name or description, number of sectors used for this program, and the memory boundary of the program. The last directory entry is usually followed by an EOV directory entry (four bytes of zeros), except when the directory is full. It is then followed by an end of directory entry (four bytes of X'FF'). A maximum of 127 entries are allowed in the directory.

9.2 OVERALL FILE STRUCTURE

Sectors 1-4 and 7-27 are unused; they are reserved for OS compatibility requirements. Sectors 28-31 are the directory. Sectors 5-6 are the FDLG boot loader. Sectors 32-2002 are available for program storage.

9.3 STARTING ADDRESSES

The FDLG starts at the following addresses:

Loader segment - X'6000'
Generator segment - X'6004'

The upper limits of the FDLG programs are X'5FFF' (24KB) and X'7FFF' (32KB) for the 16 and 32-bit processors, respectively. Any contiguous block of memory below or above the FDLG can be used for program output.

9.4 SPECIAL CONSIDERATIONS

Exercise care when specifying limits for the CREATE and UPDATE functions, because dedicated memory should not normally be altered by a program load function. Also, the MAC segmentation registers should not normally be read from or written to. Dedicated memory is defined as:

16-bit machine < X'2D0'
32-bit machine < X'A00'
