## むTfair ooblo besic REEERENOE MAMOAL VEREMON Go

The Altair BASIC lanquaqe is a high-level proaramming language specifically desianed for interactive computing systems. Its simple English-like instructions are easily understood anc quickly learned and its interactive nature allows instant feedoack of results and diagnostics. Despite i.ts simplicity, however, Altair BASIC has evolved into a powerful language with provisions for editing and string processing as well as numerical computation.

The Altair BASIC interoreter reads the instructions of the BASIC lanquage and directs the ALTAIR 8800 series microcomputer to execute them. Altair BASIC includes many useful diagnostic and editing features in all versions. The extenced versions provide adaitional features including comprehensive file input/output orocedures in the disk version.

This manual will explain the features of the BASIC lanquade and the special provisions of the $4 \mathrm{~K}, 8 \mathrm{~K}$, Extended and Disk Extended Altair BASIC interpreters, release 4.I. For quick reference, a table of Altair BASIC instructions, diagnostics and functions are provided in section 6. A complete index is at the end of the manual.

7. SOME INTRODUCTORY REMARKS

1-1 Introduction to this Manual.
a. Conventions. For the sake of simplicitv, some conventions will be followed in discussing the features of the Altair BASIC lanquage.

1. Words printed in caoital letters must be written exactly as shown. These are mostly names of instructions and commands.
2. Items enclosed in angle brackets (<>) must be supplied as explained in the text. Items in square brackets ([]) are optional. Items in both kinds of brackets, [<W>], for example, are to be supplied if the optional feature is used. Items followed by dots (...) may be repeated or deleted as necessary.
3. Shift/ or Control/ followed by a letter means the character is typed by holding down the Shift or Control key and typing the indicated letter.
4. Ali indicated ounctuation must be supplied.
b. Definitions. Some terms which will become important are as follows:

Alphanumeric character: all letters and numerals taken together are called alphanumeric characters.

Carriage Return: Refers both to the key on the terminal which causes the carriage, print head or cursor to move to the beginning of the next line and to the command that the carriage return key issues which terminates a BASIC line.

Command Level: After Altair BASIC prints OK, it is in the command level. This means it is ready to accept commands.

Commands and Statements: Instructions in Altair BASIC are loosely divided into two classes, Commands and Statements. Commands are instructions normally used only in direct mode (see Modes of Operation, section 1-2). Some commands, such as CONT, may only be used in direct mode since they have no meaning as program statements. Some commands, such as DELETE, are not normally used as program statements because they cause a return to command level. But most commands will find occasional use as progran statements. Statements are instructions that are normally used in indirect mode. Some statements, such as DEF, may only be used in indirect mode.

Edit: The orocess of deleting, adding and substituting lines in a orogram and that of preparing data for output according to a predetermined format will both be referred to as "editing." The particular meaning in use will be clear from the context.

Integer Expression: An expression whose value is truncated to an integer. The comoonents of the expression need not be of integer type.

Reserved Words: Some words are reserved by BASIC for use as statements and commands. These are called reserved words and they may not be used in variable or function names.

Special Characters: Some characters appear differently on different terminals. Some of the most important of these are the following:

```
- (carat) appears on some terminals as f (up-arrow)
~ (tilde) does not appear on some terminals and orints
        as a blank
_ (underline) appears on some terminals as <-(back-arrow).
```

String Literal: A string of characters enclosed by quotation marks (") which is to be inout or output exactly as it appears. The quotation marks are not part of the string literal, nor may a string literal contain quotation marks. (""HI, THERE""is not legal.)

Type: While the actual device used to enter information into the computer differs from system to system, this manual will use the word "type" to refer to the process of entry. The user types, the computer prints. Type also refers to the classifications of numbers and strings. The meaning will be clear from the context.

1-2 Modes of operation.
Altair BASIC provides for operation of the computer in two different modes. In the direct mode, the statements or commands are executed as they are entered into the comouter. Results of arithmetic and logical operations are displayed and stored for later use, but the instructions themselves are lost after execution. This mode is useful for debugging and for using Altair BASIC in a "calculator" mode for quick computations which do not justify the design and coding of complete programs.

In the indirect mode, the computer executes instructions from a orogram stored in memory. Program lines are entered into memory if they are preceded by a line number. Execution of the program is usually initiated by the RUN command.

1-3 Formats.
a. Lines - AUTO and RENUM. The line is the fundamental unit of an Altair BASIC proqram. The format for ah Altair BASIC line is as follows:
nnnnn <BASIC statement>[:<BASIC statement>...]
Each Altair BASIC line begins with a number. The number corresponds to the address of the line in memory and indicates the order in which the statements in the line will be executed in the orogram. It also provides for branching linkages and for editing. Line numbers must be in the range $\emptyset$ to 65529. A good programming practice is to use an increment of 5 or 10 between successive line numbers to allow for insertions.

1) Line numbers may be generated automatically in the Extended and Disk versions of Altair BASIC by use of the AUTO and RENUM commands. The AUTO command provides for automatic insertion of line numbers when entering program lines. The format of the AUTO command is as follows:

AUTO[<initial line>[,[<increment>]]
Example;
AUTO 100,10
100 INPUT $\mathrm{X}, \mathrm{Y}$
110 PRINT SQR ( $\left.X^{\sim} 2+Y^{\sim} 2\right)$
$120{ }^{\circ} \mathrm{C}$
OK
AUTO will number every input line until Control/C is typed. If the <initial line> is omitted, it is assumed to be 10 and an increment of $1 \varnothing$ is assumed if <increment> is omitted. If the <initial line> is followed by a comma but no increment is specified, the increment last used in an AUTO statement is assumed.

If AUTO generates a line number that already exists in the program currently in memory, it prints the number followed by an asterisk. This is to warn the user that any input will replace the existing line.
2) The RENUM command allows program lines to be "spread out" so that a new line or lines may be inserted between existing lines. The format of the RENUM command is as follows:
$\operatorname{RENUM}[<\mathrm{NN}\rangle[,\langle\mathrm{MM}\rangle[,\langle I \mathrm{I}\rangle]]]$
where $N N$ is the new number of the first line to be resequenced. If omitted, NN is assumed to be 10 . Lines less
than $M M$ will not be renumbered. If $M M$ is omitted, the whole program will be resequenced. II is the increment between the lines to be resequenced. If II is omitted, it is assumed to be 10. Examples:

RENUM Renumbers the whole program to start at line lo with an increment of 10 between the new line numbers.

RENUM 100,,l0 Renumbers the whole program to start at line 100 with an increment of 100 .

RENUM $6000,5000,1000$ Renumbers the lines from 5000 up so they start at 6000 with an increment of 1000 .

NOTE
RENUM cannot be used to change the order of program lines (for examole, RENUM 15,30 when the proaram has three lines numbered 10,20 and 30 ) nor to create line numbers greater than 65529. An ILLEGAL FUNCTION CALL error will result.

All line numbers appearing after a GOTO, GOSUB, THEN, ON...GOTO, ON...GOSUB and ERL<relational operator> will be properly chanqed by RENUM to reference the new line numbers. If a line number appears after one of the statements above but does not exist in the program, the messace "UNDEFINED LINE XXXXX IN YYYYY" will be printed. This line reference (XXXXX) will not be changed by RENUM, but line number YYYYY may be changed.
3) In the Extended and Disk versions, the current line number may be designated by a period (.) anywhere a line number reference is reauired. This is particularly useful in the use of the EDIT command. See section 5-4.
4) Following the line number, one or more BASIC statements are written. The first word of a statement identifies the operations to be performed. The list of arguments which follows the identifying word serves several purposes. It can contain (or refer symbolically to) the data which is to be operated upon by the statement. In some important instructions, the operation to be performed depends upon conditions or options specified in the list.

Each type of statement will be considered in detail in sections 2, 3 and 4 .

More than one statement can be written on one line if they are separated by colons (:). Any number of statements can be joined this way provided that the line is no more than 72 characters long in the 4 K and 8 K versions or 255 characters in the Extended and Disk versions. In the Extended and Disk versions, lines may be broken with the LINE FEED key. Example:

```
100 IF X<Y+37<line feed>
    THEN 5 <line feed>
    ELSE PRINT(X)<carriage return>
```

The line is shown broken into three lines, but it is inout as one BASIC line.
b. REMarks. In many cases, a program can be more easily understood if it contains remarks and explanations as well as the statements of the program oroper. In Altair BASIC, the REM statement allows such comments to be included without affecting execution of the program. The format of the REM statement is as follows:

REM <remarks>
A REM statement is not executed by BASIC, but branching statements may link into it. REM statements are terminated by the carriage return or the end of the line but not by a colon. Example:

$$
\begin{aligned}
& 100 \text { REM DO THIS LOOP:FOR I=1TOID -the FOR statement } \\
& \text { will not be executed } \\
& 101 \text { FOR I=1 TO 1月: REM DO THIS LOOP -this FOR state- } \\
& \text { ment will be execu- } \\
& \text { ted. }
\end{aligned}
$$

In Extended and Disk versions, remarks may be added to the end of a program line separated from the rest of the line by a single quotation mark ('). Everything after the single quote will be ignored.
C. Errors. When the BASIC interpreter detects an error that will cause the orogram to be terminated, it prints an error message. The error message formats in Altair BASIC are as follows:

| Direct statement | ?XX ERROR |
| :--- | :--- |
| Indirect statement | ?XX ERROR IN nnnnn |

XX is the error code or message (see section 6-5 for a list of error codes and messages) and nnnnn is the line number where the error occurred. Each statement has its own oarticular possible errors in addition to the general errors in syntax.

These errors will be discussed in the description of the individual statements.

1-4. Editing - Elementary provisions.
Editing features are orovided in Altair BASIC so that mistakes can be corrected and features can be added and deleted without affecting the remainder of the orogram. If necessary, the whole program may be deleted. Extended and Disk Altair BASIC have expanded editing facilities which will be discussed in section 5 .
a. Correcting Single Characters. If an incorrect character is detected in a line as it is being typed, it can be corrected immediately with the backarrow ( , underline on some terminals) or , except in 4 K , the RUBOUT key. Each stroke of the key deletes the immediately preceding character. If there is no preceding character, a carriage return is issued and a new line is bequn. Once the unwanted characters are removed, they can be replaced simply by typing the rest of the line as desired.

When RUBOUT is typed, a backslash ( $($ ) is printed and then the character to be deleted. Each successive RUBOUT orints the next character to be deleted. Typing a new character prints another backslash and the new character. All characters between the backslashes are deleted.

Example:

$$
\begin{array}{ll}
100 \mathrm{X}=\backslash=\mathrm{X} \backslash \mathrm{Y}=10 \quad & \text { Tyoing two RUBOUTS deleted the ' }=\text { ' } \\
& \text { and ' } \mathrm{X} \text { ' which were subsequently } \\
& \text { replaced by } \mathrm{Y}=\text {. }
\end{array}
$$

b. Correcting Lines. A line being tyoed may be deleted by typing an at-sign (@) instead of typing a carriage return. A carriage return is orinted automatically after the line is deleted. Except in $4 \hat{K}$, typing Control/U has the same effect.

In the Extended and Disk versions, tyoing control/A instead of the carriace return will allow all the features of the EDIT command (except the A command) to be used on the line currently being typed. See section 5-4.
c. Correcting Whole Programs. The NEW command causes the entire current orogram and all variables to be deletea. NEW is generally used to clear memory space preparatory to entering a new program.
2. EXPRESSIONS AND STATEMENTS.

2-1. Expressions.
The simplest BASIC expressions are single constants, variables and function calls.
a. Constants. Altair BASIC accepts integers or floating point real numbers as constants. All but the 4 K version of Altair BASIC accept string constants as well. See section 4-1. Some examples of acceotable numeric constants follow:

123
3.141
0.0436

1. $25 \mathrm{E}+05$

Data input from the terminal or numeric constants in a proqram may have any number of digits up to the length of a line (see section l-3a). In 4 K and 8 K Altair BASIC, however, only the first 7 digits of a number are significant and the seventh digit is rounded up. Therefore, the command

PRINT 1.234567890123
produces the following output:

1. 23457

OK
In Extended and Disk versions of Altair BASIC, double precision format allows 17 significant digits with the l7th digit rounded uo.

The format of a printed number is determined by the following rules:

1. If the number is negative, a minus sign (-) is orinted to the left of the number. If the number is oositive, a space is printed.
2. If the absolute value of the number is an integer in the range $\emptyset$ to 999999 , it is printed as an integer.
3. If the absolute value of the number is greater than or equal to . 01 and less than or equal to 999999, it is printed in fixed point notation with no exponent.
4. In Extended and Disk versions, fixed point values up to 9999999999999999 are Dossible.
5. If the number does not fall into categories 2,3 or 4, scientific notation is used.

The formats of scientific notation are as follows:
SX.XXXXXESTT single precision
SX.XXXXXXXXXXXXXXXDSTT double precision
where $S$ stands for the signs of the mantissa and the exponent (they need not be the same, of course), $X$ for the digits of the mantissa and $m$ for the digits of the exoonent. $E$ and $D$ may be read "...times ten to the power...." Non-significant zeros are suppressed in the mantissa, but two digits are always printed in the exponent. The sign convention in rule 1 is followed for the mantissa. The exponent must be in the range -38 to +38 . The largest number that may be represented in Altair BASIC is l.7014lE38; the smallest positive number is 2.9387E-38. The following are examples of numbers as inout and as output by Altair BASIC:

| Number | Altair BASIC Output |
| :--- | :--- |
|  |  |
| +1 | 1 |
| -1 | -1 |
| 6523 | 6523 |
| $1 E 20$ | $1 E 20$ |
| $-12.34567 E-10$ | $-1.23456 E-09$ |
| $1.234567 E-7$ | $1.23457 E-07$ |
| 1090000 | $1 E+96$ |
| .1 | .1 |
| .01 | .01 |
| .000123 | $1.23 E-04$ |
| -25.460 | -25.46 |

The Extended and Disk versions of Altair BASIC allow numbers to be reoresented in integer, single orecision or double precision form. The type of a number constant is detarmined according to the following rules:

1. A constant with more than 7 digits or a 'D' instead of 'E' in the exponent is double precision.
2. A constant outside the range -32768 to 32757 , with 7 or fewer digits and a decimal point or with an 'E' exponent is single precision.
3. A constant in the range -32768 to 32767 and no decimal point is integer.
4. A constant followed by an exclamation point (!) is single precision; a constant followed by a pound sign (\#) is double precision.

Two additional types of constants are allowed in Extended and Disk versions of Altair BASIC. Hexadecimal (base sixteen) constants may be explicitly designated by the symbol \&H preceding the number. The constant may not contain any characters other than the digits $\varnothing$ - 9 or letters A - F , or a SYNTAX ERROR will occur. Octal constants may be designated either by \&O or just the \& sign.

In all formats, a space is printed after the number. In all but the 4 K version, Altair BASIC checks to see if the entire number will fit on the current line. If not, it issues a carriage return and prints the whole number on the next line.
b. Variables. A variable represents symbolically any number which is assigned to it. The value of a variable may be assigned explicitly by the programmer or may be assiqned as the result of calculations in a program. Before a variable is assigned a value, its value is assumed to be zero. In 4K, a variable name consists of one or two characters. The first character is any letter. The second character must be a numeral. In other versions of Altair BASIC, the variable name may be any length, but any alphanumeric characters after the first two are ignored. The first character must be a letter. No reserved words may appear as variable names or within variable names. The following are examples of legal and illegal Altair BASIC variables:

Legal
In 4 K and 8 K Altair BASIC:
A
21
Other versions:
TP
PSTG\$
COUNT

Illegal
\%A (first character must be alohabetic.)
ZlA (variable name is too long for 4 K )

To (variable names cannot be reserved words)

RGOTO (variable names cannot contain reserved words.)

In all but 4 K Altair BASIC, a variable may also reoresent a string. Use of this feature is discussed in section 4 .

1) Extended and Disk versions of Altair BASIC allow the use of Integer and Double Precision variables as well as Single Precision and Strings. The type of a variable may be explicitly declared in Extended and Disk versions of Altair BASIC by using one of the symbols in the table below as the last character of the variable name.
```
Type Symbol
Strings (0 to 255 characters) $
Integers (-32768 to 32767) %
Single Precision (up to 7 digits, exponent between
    -38 and +38) !
Double Precision (up to l6 digits, exoonent between
    -38 and +38)
```

Internally, BASIC handles all numbers in binary. Therefore, some 8 digit single precision and 17 digit double precision numbers may be handled correctly. If no type is explicitly declared, type is determined by the first letter of the variable name according to the type table. The table of types may be modified with the following statements:

| DEFINT r | Integer |
| :--- | :--- |
| DEFSTR r | String |
| DEFSNG r | Single Precision |
| DEFDSL r | Double Precision |

where $r$ is a letter or range of letters to be designated. Examples:

| 15 DEFINT I-N | Variable names beqinning with the let- |
| :--- | :--- |
| 20 DEFDBL $D \quad$ | ters I-N are to be of inteaer type. |
|  | Variable names beginning with Dare to |
|  | be of double orecision type. |

If no type definition statements are encountered, BASIC proceeds as if it had executed a DEESNG A-Z statement.
2) Inteqer variables should be used wherever cossible since they take the least amount of space in memory and integer arithmetic is much faster than single precision arithmetic.

Care must be exercised when single orecision and double precision numbers are mixed. Since single precision numbers can have more significant digits than will be printed, a double precision variable set to a single precision value may not orint the same as the single precision variable.

```
10 A=1.01
20 B#=A*10:C#=CDBL(A)*10#
```

single precision value convert to double precision

```
30 PRINTA;B#;C#;CDBL(A) in various ways
RUN
    1.01 10.10000038146973 10.09999990463257 1.009999990463257
OK
```

In order to assure that double precision numbers will print the same as single precision, the VAL and STR\$ functions should be used. For example:
$10 \mathrm{~A}=1.01$
$20 \mathrm{~B} \mathrm{\#}=\mathrm{VAL}(S T R \$(A)): C \#=B \# * 1 D \#$
$3 \emptyset$ PRINT A;B\#;C\#
RUN
1.011 .0110 .1

OK
c. Array Variables - The DIM Statement. It is often advantageous to refer to several variables by the same name. In matrix calculations, for example, the computer handles each element of the matrix separately, but it is convenient for the programmer to refer to the whole matrix as a unit. For this purpose, Altair BASIC provides subscripted variables, or arrays. The form of an array variable is as follows:

VV(<subscript>[,<subscriọt>...])
where $V V$ is a variable name and the subscripts are integer expressions. Subscripts may be enclosed in parentheses or square brackets. An array variable may have only one dimension in 4 K , but in all other versions of Altair BASIC it may have as many dimensions as will fit on a single line. The smallest subscript is zero. Examples:

A(5) The sixth element of array $A$. The first element is $A(0)$.
ARRAY (I, $2 * J$ ) The address of this element in a twodimensional array is determined by evaluating the expressions in parentheses at the time of the reference to the array and truncating to inteqers. If $I=3$ and $J=2.4$, this refers to ARRAY $(3,4)$.

The DIM statement allocates storage for array variables and sets all array elements to zero. The form of the DIM statement is as follows:

```
DIM VV(<subscript>[,<subscript>...])
```

where VV is a leqal variable name. Subscript is an integer expression which specifies the largest possible subscript for that dimension. Each DIM statement may aoply to more than one array variable. Some examples follow:

```
113 DIM A(3), D$(2,2,2)
```

114 DIM R2\% (4), B(10)
115 DIM Ql(N), Z\# (2+I) Arrays may be dimensioned dy-
namically during program
execution. At the time the
DIM is executed, the expression
within the parentheses is e-
valuated and the results trun-
cated to integer.

If no DIM statement has been executed before an array variable is found in a oroqram, BASIC assumes the variable to have a maximum subscript of 10 (ll elements) for each dimension in the reference. A BS or SUBSCRIPT OUT OF RANGE error message will be issued if an attempt is made to reference an array element which is outside the space allocated in its associated DIM statement. This can occur when the wrong number of dimensions is used in an array element reference. For example:
$30 \operatorname{LET} A(1,2,3)=X$ when $A$ has been dimensioned by 19 DIM $A(2,2)$

A DD or REDIMENSIONED ARRAY error occurs when a DIM statement for an array is found after that array has been dimensioned. This often occurs when a DIM statement appears after an array has been given its default dimension of 10.
d. Operators and Precedence. Altair BASIC provides a full range of arithmetic and (except in 4 K ) logical operators. The order of execution of operations in an expression is always according to their precedence as shown in the table below. The order can be specified explicitly by the use of parentheses in the normal algebraic fashion.

## Table of Precedence

Operators are shown here in decreasing order of precedence. Operators listed in the same entry in the table have the same precedence and are executed in order from left to right in an expression.

1. Expressions enclosed in parentheses ()
2.     - exponentiation (not in 4 K ). Any number to the zero power is l. Zero to a negative power causes a / or DIVISION BY ZERO error.
3.     - negation, the unary minus operator

- 4. *,/ multiplication and division

5. \ integer division (available in Extended and Disk versions, see section 5-2)
6. MOD (available in Extended and Disk versions. See section 5-2)
7. +,- addition and subtraction
8. relational operators
= equal
<> not equal
< less than
> greater than
$<=,=<$ less than or equal to
$>=, \Rightarrow$ greater than or equal to
(the logical operators below are not available in 4K)
9. NOT logical, bitwise negation
10. AND logical, bitwise disjunction
11. OR logical, bitwise conjunction
(The logical operators below are available only in Extended and Disk versions.)
12. XOR logical, bitwise exclusive OR
13. EQV logical, bitwise equivalence
14. IMP logical, bitwise implication

In 4 K Altair BASIC, relational operators may be used only once in an IF statement. In all other versions, relational operators may be used in any expressions. Relational expressions have the value either of True (-1) or False (0).
e. Logical Operations. Logical operators may be used for bit manipulation and Boolean algebraic functions. The AND, OR, NOT, XOR, EQV and IMP operators convert their arguments into sixteen bit, signed, two's complement integers in the range -32768 to 32767. After the operations are performed, the result is returned in the same form and range. If the arguments are not in this range, an $F C$ or ILLEGAL FUNCTION CALI error message will be printed and execution will be terminated. Truth tables for the logical overators apoear below. The operations are performed bitwise, that is,
corresponaing bits of each argument are examined and the result computed one bit at a time. In binary operations, bit 7 is the most significant bit of a byte and bit 0 is the least significant.

AND

| $X$ | $Y$ | $X$ | AND |
| :---: | :---: | :---: | :---: |
| Y |  |  |  |
| 1 | 1 |  | 1 |
| 1 | 0 |  | 0 |
| 0 | 1 |  | 0 |
| 0 | 0 |  | 0 |
|  |  |  |  |

OR

| X | Y | X OR | $Y$ |
| :---: | :---: | :---: | :---: |
| 1 | 1 | 1 |  |
| 1 | 0 | 1 |  |
| 0 | 1 | 1 |  |
| 0 | 0 | 0 |  |

NOT

| $X$ | NOT $X$ |
| :---: | :---: |
| 1 | 0 |
| 0 | 1 |

XOR

| $X$ | $Y$ | $X$ | XOR |
| :---: | :---: | :---: | :---: |
| $X$ | $Y$ |  |  |
| 1 | 1 |  | 0 |
| 1 | 0 |  | 1 |
| 0 | 1 |  | 1 |
| 0 | 0 |  | 0 |

EQV

| $X$ | $Y$ | $X$ | $E Q V$ |
| :--- | :---: | :---: | :---: |
| 1 | 1 |  | 1 |
| 1 | 0 |  | 0 |
| 0 | 1 |  | 0 |
| 0 | 0 |  | 1 |

IMP

| $X$ | $Y$ | $X$ | $I M P$ |
| :--- | :---: | :---: | :---: |$\quad Y$

Some examples will serve to show how the logical ocerations work:

| 63 AND $16=16$ | 63=binary 111111 and $16=$ binary 10000 , so 63 AND $15=16$ |
| :---: | :---: |
| 15 AND $14=14$ | $15=$ binary 1111 and $14=$ binary 1110 , |
|  | so 15 AND $14=$ binary $1110=14$. |
| -1 AND $8=8$ | -l=binary ll11111111111111 and 8=binary |
|  | 1000, so -1 AND 8=8. |
| 4 OR 2=6 | $4=$ binary lob and $2=$ binary 10, so |
|  | 4 OR 2=binary 110才 6 . |
| 10 OR $10=10$ | binary lolo OR'd with itself is lolg= |

```
10.
-l=binary lllllllllllll111 and -2=
    ll11111111111110, so -1 OR -2=-1.
    the bit complement of sixteen zeros
    is sixteen ones, which is the two's
    complement reoresentation of -1.
NOT X=-(X+I) the two's comolement of any number is
    the bit complement plus one.
```

-1 OR -2=-1
NOT $\emptyset=-1$

NOT $X=-(X+1)$
10.
-l=binary lllllllllllllll and -2= ll11111111111110, so -1 OR $-2=-1$. the bit complement of sixteen zeros is sixteen ones, which is the two's complement reoresentation of -1 . the two's comolement of any number is the bit complement olus one.

A typical use of logical operations is 'masking', testing a binary number for some predetermined pattern of bits. Such numbers might come from the computer's input ports and would then reflect the condition of some external device. Further applications of logical operations will be considered in the discussion of the IF statement.
f. The LET statement. The LET statement is used to assign a value to a variable. The form is as follows:

LET 〈VV〉=<expression>
where $V V$ is a variable name and the expression is any valid Altair BASIC arithmetic or, except in $4 K$, logical or string expression. Examples:

1000 LET $V=\mathrm{X}$
$110 \operatorname{LET} I=I+1$ the '=' sign here means 'is reolaced by ....'

The word LET in a LET statement is optional, so algebraic equations such as:
$120 V=.5^{*}(X+2)$
are legal assignment statements.
A SN or SYNTAX ERROR message is printed when BASIC detects incorrect form, illegal characters in a line, incorrect punctuation or missing parentheses. An oV or OVERFLOW error occurs when the result of a calculation is too large to be represented by Altair BASIC's number formats. All numbers must be within the range $1 E-38$ to $1.70141 E 38$ or $-1 E-38$ to -1.70141E38. An attempt to divide by zero results in the / $\emptyset$ or DIVISION BY ZERO error message.

For a discussion of strings, string variables and string operations, see section 4.

2-2. Branching, Loops and Subroutines.
a. Branching. In addition to the sequential execution of program lines, BASIC provides for changing the order of execution. This orovision is called branching and is the basis of programmed decision making and loops. The statements in Altair BASIC which provide for branching are the GOTO, IF...THEN and ON...GOTO statements.

1) GOTO is an unconditional branch. Its form is as follows:

GOTO<mmmmm>
After the GOTO statement is executed, execution continues at line number mmmm.
2) IF...THEN is a conditional branch. Its form is as follows:

## IF<expression>THEN<mmmmm>

where the expression is a valid arithmetic, relational or, except in 4 K, logical expression and mmmm is a line number. If the expression is evaluated as non-zero, BASIC continues at line mmmm. Otherwise, execution resumes at the next line after the IF...THEN statement.

An alternate form of the IF...THEN statement is as follows:

IF<expression>THEN<statement>
where the statement is any Altair BASIC statement. Examples:

```
10 IF A=10 THEN 40 If the expression A=10 is
    true, BASIC branches to line 40. Otherwise, execution
    proceeds at the next line.
15 IF \(A \angle B+C\) OR \(X\) THEN IDD The expression after IF is evaluated and if the value of the expression is non-zero, the statement branches to line 100. Otherwise, execution continues on the next line.
20 IF \(X\) THEN 25 If \(X\) is not zero, the statement branches to line 25 .
```

30 IF $X=Y$ THEN PRINT $X$ If the expression $X=Y$ is true (its value is non-zero), the PRINT statement is executed. Otherwise, the PRINT statement is not executed. In either case, execution continues with the line after the IF...THEN statement.
35 IF $X=Y+3$ GOTO 39 Equivalent to the corresoonding IF...THEN statement, except that GOTO must be followed by a line number and not by another statement.

Extended and Disk versions of Altair BASIC provide an expanded IF...THEN statement of the form

IF<expression>THEN<YY>ELSE<ZZ>
where $Y Y$ and $Z Z$ are valid line numbers or Altair BASIC statements. Examples:

IF X>Y THEN PRINT "GREATER" ELSE PRINT "NOT GREATER"
If the expression $X>Y$ is true, the statement after THEN is executed. Otherwise, the statement after ELSE is executed.

IF $X=2 * Y$ THEN 5 ELSE PRINT "ERROR"
If the expression $X=2 * Y$ is true, BASIC branches to line 5. Otherwise, the PRINT statement is executed. Extended and Disk Altair BASIC allow a comma before THEN.

IF statements may be nested in the Extended and Disk versions. Nesting is limited only by the length of the line. Thus, for example:

IF $X>Y$ THEN PRINT "GREATER" ELSE IF Y>X<line feed>
THEN PRINT "LESS THAN" ELSE PRINT "EQUAL"
and

> IF $X=Y$ THEN IF $Y>Z$ THEN PRINT "X>Z" ELSE PRINT "Y<=Z" <line feed> ELSE PRINT "X<>Y"
are legal statements. If a line does not contain the same number of ELSE and THEN clauses, each ELSE is matched with the closest unmatched THEN. Example:

IF $A=B$ THEN IF $B=C$ THEN PRINT " $A=C$ " ELSE PRINT "A<>C"
will not orint "A<>C" when $A<>B$.
3) ON...GOTO (not in $4 K$ ) provides for another tvoe of conditional branch. Its form is as follows:

ON<expression>GOTO<list of line numbers>
After the value of the expression is truncated to an integer, say $I$, the statement causes BASIC to branch to the line whose number is Ith in the list. The statement may be followed by as many line numbers as will fit on one line. If $I=d$ or is greater than the number of lines in the list, execution will continue at the next line after the ON...GOTO statement. I must not be less than zero or greater than 255, or an FC or ILLEGAL FUNCTION CALL error will result.
b. Loops - FOR and NEXT. It is often desirable to perform the same calculations on different data or repetitively on the same data. For this purpose, Altair BASIC provides the FOR and NEXT statements. The form of the FOR statement is as follows:

## FOR<variable>=<X>TO<Y>[STEP <Z>]

where $X, Y$ and $Z$ are expressions. When the $F O R$ statement is encountered for the first time, the expressions are evaluated. The variable is set to the value of $x$ which is called the initial value. BASIC then executes the statements which follow, the $F O R$ statement in the usual manner. When a NEXT statement is encountered, the step $Z$ is added to the variable which is then tested against the final value $Y$. If $Z$, the step, is positive and the variable is less than or equal to the final value, or if the steo is negative and the variable is greater than or equal to the final value, then BASIC branches back to the statement immediately following the $F O R$ statement. Otherwise, execution oroceeds with the statement following the NEXT. If the step is not specified, it is assumed to be 1. Examples:

10 FOR $I=2$ TO 11 The loop is executed 19 times with the variable I taking on each integral value from 2 to 11.
20 FOR V=1 TO 9.3 This loop will execute 9 times until $V$ is greater than 9.3
30 FOR V=10*N TO $3.4 / Z \operatorname{STEP} \operatorname{SQR}(R)$ The initial, final and step expressions need not be integral, but thev will be evaluated only once before looping begins.
40 FOR V=9 TO 1 STEP -1 This loop will be executed 9 times.

FOR...NEXT loops may be nestea. That is, BASIC will execute a FOR...NEXT loop within the context of another loop. An example of two nested loops follows:

100 FOR $I=1$ TO 10
120 FOR J=1 TO I
130 PRINT A (I,J)
140 NEXT J
150 NEXT I
Line 130 will orint 1 element of $A$ for $I=1,2$ for $I=2$ and so on. If loops are nested, they must have different loop variable names. The NEXT statement for the inside loop variable (J in the example) must appear before that for the outside variable (I). Any number of levels of nesting is allowed uo to the limit of available memory.

The NEXT statement is of the form:
NEXT[<variable>[,<variable>...]]
where each variable is the loop variable of a FOR loop for which the NEXT statement is the end point. In the 4 K version, the only form allowed is NEXT with one variable. In all other versions, NEXT without a variable will match the most recent FOR statement. In the case of nested loods which have the same end point, a single NEXT statement may be used for all of them, except in 4K. The first variable in the list must be that of the most recent loop, the second of the next most recent, and so on. If BASIC encounters a NEXT statement before its corresponding FOR statement has been executed, an NF or NEXT WITHOUT FOR error message is issued and execution is terminated.
c. Subroutines - GOSUB and RETURN Statements. If the same operation or series of onerations are to be performed in several places in a program, storage space requirements and programming time will be minimized by the use of subroutines. A subroutine is a series of statements which are executed in the normal fashion upon being branched to by a GOSUB statement. Execution of the subroutine is terminated by the RETURN, statement which branches back to the statement after the most recent GOSUB. The format of the GOSUB statement is as follows:

GOSUB<line number>
where the line number is that of the first line of the subroutine. A subroutine may be called from more than one place in a program, and a subroutine may contain a call to another subroutine. Such subroutine nesting is limited only by available memory.

Except in the 4 K version, subroutines may be branched to conditionally by use of the ON...GOSUB statement, whose form is as follows:

ON <expression> GOSUB <list of line numbers>
The execution is the same as ON...GOTO except that the line numbers are those of the first lines of subroutines. Execution continues at the next statement after the ON...GOSUB upon return from one of the subroutines.
d. Memory Limitations. While nesting in loops, subroutines and branching is not limited by BASIC, memory size limitations restrict the size and complexity of programs. The OM or OUT OF MEMORY error message is issued when a program requires more memory than is available. See Appendix $C$ for an
explanation of the amount of memory required to run programs.

## 2-3. Input/Output

a. INPUT. The INPUT statement causes data input to be requested from the terminal. The format of the INPUT statement is as follows:

## INPUT<list of variables>

The effect of the INPUT statement is to cause the values typed on the terminal to be assigned to the variables in the list. When an INPUT statement is executed, a question mark (?) is printed on the terminal signalling a request for information. The operator types the reguired numbers or strings (or, in $4 k$, expressions) separated by commas and types a carriage return. If the data entered is invalid (strings were entered. when numbers were requested, etc.) BASIC prints 'REDO EROM START?' and waits for the correct data to be entered. If more data was requested by the INPUT statement than was typed, ?? is printed on the terminal and execution awaits the needed data. If more data was typed than was requested, the warning 'EXTRA IGNORED' is printed and execution proceeds. After all the requested data is indut, execution continues normally at the statement following the INPUT. Except in 4 K , an optional prompt string may be added to an INPUT statement.

INPUT["<prompt string>";]<variable list>
Execution of the statement causes the prompt string to be printed before the question mark. Then all operations proceed as above. The prompt string must be enclosed in double quotation marks (") and must be separated from the variable list by a semicolon (;). Example:
l00 INPUT "WHAT'S THE VALUE"; $\mathrm{X}, \mathrm{Y}$ causes the following output:

WHAT'S THE VALUE?

The requested values of $X$ and $Y$ are typed after the ? Except in 4 K , a carriage return in response to an INPUT statement will cause execution to continue with the values of the variables in the variable list unchanged. In $4 \mathrm{~K}, \mathrm{a}$ SN error results.
b. PRINT. The PRINT statement causes the terminal to print data. The simplest PRINT statement is:

PRINT
which prints a carriage return. The effect is to skip a line. The more usual PRINT statement has the following, form:

PRINT<list of expressions>
which causes the values of the expressions in the list to be printed. String literals may be printed if they are enclosed in quotation marks (").

The position of printing is determined by the ounctuation used to separate the entries in the list. Altair BASIC divides the printing line into zones of 14 spaces each. A comma causes printing of the value of the next expression to begin at the beginning of the next 14 column zone. A semicolon (;) causes the next printing to begin immediately after the last value printed. If a comma or semicolon terminates the list of expressions, the next PRINT statement begins printing on the same line according to the conditions above. Otherwise, a carriage return is printed.
c. DATA, READ, RESTORE

1) The DATA statement. Numerical or string data needed in a program may be written into the program statements themselves, input from peripheral devices or read from DATA statements. The format of the DATA statement is as follows:

DATA<list>
where the entries in the list are numerical or string constants separated by commas. In $4 k$, expressions may also appear in the list. The effect of the statement is to store the list of values in memory in coded form for access by the READ statement. Examples:

10 DATA 1,2,-1E3,.04
20 DATA "LOO", MITS Leading and trailing spaces in string values are suporessed unless the string is enclosed by double quotation marks.
2) The READ statement. The data stored by DATA statements is accessed by READ statements which have the following form:

> READ<list of variables>
where the entries in the list are variable names separated by commas. The effect of the ReAD statement is to assign the values in the DATA lists to the corresponding variables in the READ statement list. This is done one by one from left to right until the READ list is exhausted. If there are more names in the READ list than values in the DATA lists, an $O D$

OUT OF DATA error message is issued. If there are more values stored in DATA statements than are read by a READ statement, the next READ statement to be executed will begin with the next unread DATA list entry. A single READ statement may access more than one DATA statement, and more than one READ statement may access the data in a single DATA statement.

An $S N$ or SYNTAX ERROR message can result from an improperly formatted DATA list. In $4 K$ Altair BASIC, the error message will refer to the READ statement which attempted to access the incorrect data. In other versions, the line number in the error message will refer to the actual line of the DATA statement in which the error occurred.
3) The RESTORE statement. After the RESTORE statement is executed, the next piece of data accessed by a READ statement will be the first entry of the first DATA list in the program. This allows re-READing the data.
d. CSAVE and CLOAD ( 8 K cassette, Extended and Disk versions only). Numeric arrays may be saved on cassette or loaded from cassette using CSAVE* and CLOAD*. The formats of the statements are:

CSAVE*<array name>
and
CLOAD*<array name>
The array is written out in binary with four octal 210 header bytes to indicate the start of data. These bytes are searched for when CLOADing the array. The number of bytes written is four plus:

```
8*<number of elements> for a double precision array
4*<number of elements> for a single precision array
2*<number of elements> for an integer array
```

When an array is written out or read in, the elements of the array are written out with the leftmost subscript varying most quickly, the next leftmost second, etc:

DIM A(10)
CSAVE*A
writes out $A(0), A(1), \ldots A(10)$
DIM A 10,10$)$
CSAVE*A
writes out $A(0,0), A(1,0) \ldots A(10, \theta), A(10,1) \ldots A(10,10)$
Using this fact, it is possible to write a two dimensional array and read it back in as a single dimensional array, etc.

## NOTE

Writing out a double precision array and reading it back in as a single precision or integer array is not recommended. Useless values will undoubtedly be returned.
e. Miscellaneous Input/Output

1) WAIT (not in 4 K ). The status of input ports can be monitored by the WAIT command which has the following format:

WAIT<I,J>[,<K>]
where $I$ is the number of the port being monitored and $J$ and $K$ are integer expressions. The port status is exclusive ORd with $K$ and the result is ANDed with $J$. Execution is suspended until a non-zero value results. J picks the bits of port I to be tested and execution is suspended until those bits differ from the corresponding bits of $K$. Execution resumes at the next statement after the $N A I T$. If $K$ is omitted, it is assumed to be zero. I, $J$ and $K$ must be in the range g to 255 . Examples:

WAIT 20,6 Execution stops until either bit lor bit 2 of port 2 g are equal to l. (Bit 0 is least significant bit, 7 is the most significant.) Execution resumes at the next statement.

WAIT 10,255,7 Execution stops until any of the most significant 5 bits of oort 10 are one or any of the least significant 3 bits are zero. Execution resumes at the next statement.
2) POKE, PEEK (not in 4K). Data may be entered into memory in binary form with the FORE statement whose format is as follows:

POKE 〈I,J〉
where $I$ and $J$ are integer expressions. POKE stores the byte $J$ into the location specified by the value of I. In 8 K , I must be less than 32769. In Extended and Disk versions, I may be in the range 0 to 65535. J must be in the range 0 to 255. In 8K, data may be POKEd into memory above location 32768 by making I a neqative number. In that case, I is computed by subtracting 65536 from the desired address. TO POKE data into location 45000 , for example, $I$ is $45000-65536=-20536$. Care must be taken not to POKE data into the storage area occupied by Altair BASIC or the system may be POKEd to death, and BASIC will have to be loaded again.

The complementary function to PORE is PEEK. The format for a PEEK call is as follows:
$\operatorname{PEER}(\langle I\rangle)$
where $I$ is an integer expression specifying the address from which a byte is read. I is chosen in the same way as in the POKE statement. The value returned is an integer between $D$ and 255. A major use of PEEK and POKE is to pass arguments and results to and from machine language subroutines.
3)OUT, INP (not in 4 K ). The format of the OUT statement is as follows:

OUT 〈I,J〉
where $I$ and $J$ are inteqer expressions. OUT sends the byte signified by $J$ to output port $I$. $I$ and $J$ must be in the range ® to 255 .

The INP function is called as follows:
INP (<I>)
INP reads a byte from port $I$ where $I$ is an integer expression in the range 0 to 255. Example:
$20 \operatorname{IF} \operatorname{INP}(J)=16$ THEN PRINT "ON"

## 3. FUNCTIONS.

Altair BASIC allows functions to be referenced in mathematical function notation. The format of a function call is as follows:
<name>(<argument> [,<argument>...])
where the name is that of a previously defined function and the arguments are one or more expressions separated by commas. Only one argument is allowed in 4 K and 8 K . Function calls may be components of expressions, so statements like

```
10 LET T=(F*SIN(T))/P and
2\emptysetC=SQR(A`2+B^2+2*A*B*COS(T))
```

are legal.

3-1. Intrinsic Functions
Altair BASIC provides several frequently used functions which may be called from any program without further definition. A procedure is provided, however, whereby unneeded functions may be deleted to save memory space. See Appendix B. For a list of intrinsic functions, see section 6-3.

3-2. User-Defined Functions $=$ the DEF Statement (not in 4 K ).
a. The DEF statement. The programmer may define functions which are not included in the list of intrinsic functions by means of the DEF statement. The form of the DEF statement is as follows:

DEF<function name>(<variable list>)=<expression>
where the function name must be $F N$ followed by a legal variable name and the entries in the variable list are 'dummy' variable names. The dummy variables represent the argument variables or values in the function call. In 8K Altair BASIC, only one argument is allowed for a user-defined function, but in the Extended and Disk versions, any number of arguments is allowed. Any expression may appear on the right side of the equation, but it must be limited to one line. User-defined functions may be of any type in Extended and Disk versions, but user-defined string functions are not allowed in 8K. If a type is specified for the function, the value of the expression is forced to that tyoe before it is returned to the calling statement. Examples:
$10 \operatorname{DEF} \operatorname{FNAVE}(\mathrm{~V}, \mathrm{~W})=(\mathrm{V}+\mathrm{W}) / 2$
11 DEF FNCONS (V\$,W\$) $=$ RIGHT\$ (V\$+W\$,5) Returns the riaht most 5 characters of the concatenation of $V \$$ and $w \$$.
12 DEF FNRAD(DEG) $=3.14159 / 18$ g*DEG When called with the measure of an angle in degrees, returns the radian equivalent.

A function may be redefined by executing another DEF statement with the same name. A DEF statement must be executed before the function it defines may be called.
b. USR. The USR function allows calls to assembly language subroutines. See appendix E.

3-3. Errors.
a. An FC or ILLEGAL FUNCTION CALL error results when an improper call is made to a function. Some places this might occur are the following:

1. a negative array subscript. LET $A(-1)=0$, for example.
2. an array subscript that is too large (>32767)
3. negative or zero argument for LOG
4. Negative argument for $S Q R$
5. $A^{\prime} B$ with $A$ negative and $B$ not an integer
6. a call to USR with no address patched for the machine language subroutine.
7. improper arguments to MID\$, LEFT\$ ,RIGHT\$, INP, OUT, WAIT, PEEK, POKE, TAB, SPC, INSTR, STRING\$, SPACE\$ or ON... GOTO.
b. An attempt to call a user-defined function which has not previously appeared in a DEF statement will cause a UF or UNDEFINED USER FUNCTION error.
c. A TM or TYPE MISMATCH error will occur if a function which expects a string argument is given a numeric value or vice-versa.
8. STRINGS

In all Altair BASIC versions except 4 K , expressions may either have numeric value or may be strings of characters. Altair BASIC provides a complete complement of statements and functions for manipulating string data. Many of the statements have already been discussed; so ,only their particular apolication to strings will be treated in this section.

## 4-1. String Data.

A string is a list of characters which may be from g to 255 characters in length. Strings may be stated explicitly as constants or referred to symbolically by variables. String constants are delimited by quotation marks at the beqinning and end. A string variable name ends with a dollar sign (\$). Examples:

| $A S=" A B C D "$ | Sets the variable AS to the four character |
| :--- | :--- |
| string "ABCD" |  |
| Sets the variable $B 9 \$$ to the six character |  |

Strings input to an INPUT statement need not be surrounded by quotation marks.

String arrays may be dimensioned exactly as any other kind of array by use of the DIM statement. Each element of a string array is a string which may be up to 255 characters long. The total number of string characters in use at any point in the execution of a program must not exceed the total allocation of string space, or an OS or OUT OF STRING SPACE error will result. String soace is allocated by the CLEAR command which is explained in section 6-2.

4-2. String Operations.
a. Comparison Operators. The comparison operators for strings are the same as those for numbers:

```
= equal
<> not equal
< less than
> greater than
=<,<= less than or equal to
=>,>= greater than or equal to
```

Comparison is made character by character on the basis of

ASCII codes until a difference is found. If, while comparison is proceeding, the end of one string is reached, the shorter string is considered to be smaller. ASCII codes may be found in Appendix A. Examples:

| A<Z | ASCII A is $965, \mathrm{Z}$ is 990 |
| :--- | :--- |
| l<A | ASCII 1 is 949 |
| "A">"A" | Leading and trailing blanks are significant |
|  | in string literals. |

b. String Expressions. String expressions are composed of string literals, string variables and string function calls connected by the concatenation operator (+). The effect of the catenation operator is to add the string on the right side of the operator to the end of the string on the left. If the result of concatenation is a string more than 255 characters long, an LS or STRING TOO LONG error message will be issued and execution will be terminated.
c. Input/Output. The same statements used for input and output of normal numeric data may also be used for strina data.

1) INPUT, PRINT. The INPUT and PRINT statements read and write strings on the terminal. Strings need not be enclosed in quotation marks, but if they are not, leading blanks will be ignored and the string will be terminated when the first comma or colon is encountered. Examples:

10 INPUT ZOOS,FOO\$
20 INPUT $\mathrm{X} \$$
30 PRINT XṢ,"HI, THERE"

Reads two strings
Reads one string and assigns it to the variable $\mathrm{X} \$$.
Prints two strings, including all spaces and punctuation in the second.
2) DATA, READ. DATA and READ statements for string data are the same as for numeric data. For format conventions, see the explanation of INPUT and PRINT above.

4-3. String Functions.

The format for intrinsic string function calls is the same as that for numeric functions. For the list of string functions, see section 6-3. Soecial user-defined string functions are allowed in Extended and Disk versions and may be defined by the use of the DEF statement (see section 3-2). String function names must end with a dollar sign.
5. EXTENDED VERSIONS.

The Extended and Disk versions of Altair BASIC provide several statements, operators, functions and commands which are not available either in the 4 K or 8 K versions. For clarity, these features are grouped together in this section. Some modifications to existing 4 K and 8 K features, such as the IF...THEN...ELSE statement and number typing facilities, have been discussed in conjunction with the other versions. Check the index for references to those features.

5-1. Extended Statements
a. ERASE. The ERASE statement eliminates arrays from a program and allows their space in memory to be used for other purposes. The format of the ERASE statement is as follows:

ERASE<array variable list>
where the entries in the list are valid array variable names separated by commas. ERASE will only operate on arrays and not array elements. If a name appears in the list which is not used in the program, an ILLEGAL FUNCTION CALL error will occur. The arrays deleted in an ERASE statement may be dimensioned again, but the old values are lost. Example:
$10 \operatorname{DIM} A(5,5) \quad$ etc.
•
60 ERASE A
70 DIM A $(10 \theta)$
b. LINE INPUT. It is often desirable to inout a whole line to a string variable without use of guotation marks and other delimiters. LINE INPUT provides this facility. The format of the LINE INPUT statement is as follows:

IINE INPUT ["<orompt string>"];<string variable name>
The prompt string is a string literal that is orinted on the terminal before inout is accepted. A question mark is not printed unless it is contained in the orompt string. All input from the end of the orompt string to the carriage return is assigned to the string variable. A LINE INPUT may be escaped by tyoing Control/C. At that point, BASIC returns to command level and prints OK. Execution may be resumed at the LINE INPUT by typing CONT. LINE INPUT destroys the inout buffer, so the command may not be edited by Control/A for
re-execution.
c. SWAP. The SWAP statement allows the values of two variables to be exchanged. The format is as follows:

SWAP <variable,variable>
The value of the second variable is assigned to the first variable and vice-versa. Either or both of the variables may be elements of arrays. If one or both of the variables are non-array variables which have not had values assigned to them, an ILLEGAL FUNCTION CALL error will result. Both variables must be of the same type or a TYPE MISMATCH error will result. Example:

10 INPUT FS,L\$
20 SWAP F\$,L\$
30 PRINT F\$,L\$
RUN
?FIRST,LAST
FIRST
Data input
LAST
Computer prints
d. TRON, TROFF. As a debugging aid, two statements are provided to trace the execution of program instructions. When the trace flag is turned on by the TRON statement, the number of each line in the program is printed as it is executed. The numbers appear enclosed in square brackets ([]). The function is disabled by execution of the TROFF statement. Example:

The NEW command will also turn off the trace flag.
e. IF...THEN...ELSE. See section 2-2.
f. DEFINT, DEFSNG, DEFDBL, DEFSTR. See section 2-1
g. CONSOLE, WIDTH. CONSOLE allows the console terminal to be switched from one I/O port to another. The format of the statement is:

CONSOLE <I/O port number>, <switch register setting>

The <I/O port number> is the hardware port number of the low order (status) port of the new I/O board. This value must be a numeric expression between $g$ and 255 inclusive. If it is not in this range, an ILLEGAL FUNCTION CALL error will occur. The <switch register setting> is also a value between 0 and 255 inclusive which specifies the type of I/O port (SIO, PIO, 4 PIO etc) being selected. Aporopriate values of the sswitch register setting> may be found in Appendix $B$ in the table of sense switch settings or in the table below.

Table of values for <switch register setting>:
I/O Board Sense Switch
Setting

| 2SIO with 2 stop bits | 0 |
| :--- | ---: |
| 2SIO with 1 stoo bit | 1 |
| SIO |  |
| ACR |  |
| 4PIO | 3 |
| PIO | 4 |
| HSR | 5 |
| non-standard terminal | 5 |
| no terminal | 14 |

WIDTH Statement

The WIDTH statement sets the width in characters of the printing terminal line. The format of the WIDTH statement is as follows:

WIDTH <integer expression>
Example:
WIDTH 80
WIDTH 32
The <numeric formula> must have a value between 15 and 255 inclusive, or an ILLEGAL FUNCTION CALL error will occur.
h. Error Trapoing. Extended and Disk Altair BASIC make it possible for the user to write error detection and handing routines which can attemot to recover from errors or provide more complete explanation of the cause of errors than the simple error messages. This facility has been added to Altair BASIC through the use of the ON ERROR GOTO, RESUME and ERROR
statements and with the ERR and ERL variables.

1) Enabling Error Trapoing. The ON ERROR GOTO statement specifies the line of the Altair BASIC program on which the error handing subroutine starts. The format is as follows:

ON ERROR GOTO <line number>
The ON ERROR GOTO statement should be executed before the user expects any errors to occur. Once an ON ERROR GOTO statement has been executed, all errors detected will cause BASIC to start execution of the specified error handing routine. If the <line number> specified in the ON ERROR GOTO statement does not exist, an UNDEFINED LINE error will occur.

Example:
10 ON ERROR GOTO 1000
2) Disabling the Error Routine. ON ERROR GOTO disables trapping of errors so any subsequent error will cause BASIC to print an error message and stop program execution. If an ON ERROR GOTO 0 statement appears in an error trapoing subroutine, it will cause BASIC to stop and print the error message which caused the trap. It is recommended that all error trapping subroutines execute an ON ERROR GOTO g subroutine if an error is encountered for which they have no recovery action.

NOTE
If an error occurs during the execution of an error trap routine, the system error message will be printed and execution will be terminated. Error trapping does not trap errors within the error trap routine.
3) The ERR and ERL Variables. When the error handling subroutine is entered, the variable ERR contains the error code for the error. The error codes and their meanings are listed below. See section $6-5$ for a detailed discussion of each of the errors and error messages.

Code Error
1 NEXT WITHOUT FOR
2 SYNTAX ERROR

| 3 | RETURN WITHOUT GOSUB |
| :--- | :--- |
| 4 | OUT OF DATA |
| 5 | ILLEGAL FUNCTION CALL |
| 6 | OVERFLOW |
| 7 | OUT OF MEMORY |
| 8 | UNDEFINED LINE |
| 9 | SUBSCRIPT OUT OF RANGE |
| 10 | REDIMENSIONED ARRAY |
| 11 | DIVISION BY ZERO |
| 12 | ILLEGAL DIRECT |
| 13 | TYPE MISMATCH |
| 14 | OUT OF STRING SPACE |
| 15 | STRING TOO LONG |
| 16 | STRING FORMULA TOO COMPLEX |
| 17 | CANT CONTINUE |
| 18 | UNDEFINED USER FUNCTION |
| 19 | NO RESUME |
| 20 | MISSING OPERAND |
| 21 | RESUME WITHOUT ERROR |
| 22 | UNPRINTABLE ERROR |
| 23 | LINE BUFFER OVERFLOW |
|  |  |
| DiSk ETrOIS |  |
| 50 | FIELD OVERFLOW |
| 51 | INTERNAL ERROR |
| 52 | BAD FILE NUMBER |
| 53 | FILE NOT FOUND |
| 54 | BAD FILE MODE |
| 55 | FILE ALREADY OPEN |
| 56 | DISK NOT MOUNTED |
| 57 | DISK I/O ERROR |
| 58 | FILE ALREADY EXISTS |
| 59 | SET TO NON-DISK STRING |
| 60 | DISK ALREADY MOUNTED |
| 61 | DISK FULL |
| 62 | INPUT PAST END |
| 63 | BAD RECORD NUMBER |
| 64 | BAD FILE NAME |
| 65 | MODE-MISMATCH |
| 66 | DIRECT STATEMENT IN FILE |
| 67 | TOO MANY FILES |
| 68 | OUT OF RANDOM BLOCKS |
|  |  |

occurred in a direct statement, use
IF 65535=ERL THEN ...
In all other cases, use
IF ERL=<line number> THEN...
If the line number is on the left of the equation, it cannot be renumbered by RENUM (see section l-la).
4) Disk Error Values - The ERR function. The ERR function returns the parameters of a DISK I/O ERROR. ERR(D) returns the number of the disk, ERR(1) returns the track number ( $0-76$ ) and ERR(2) returns the sector number ( $0-31$ ). ERR(3) and ERR(4) contain the low and high order bytes, respectively, of the cumulative error count since BASIC was loaded.

NOTE
Neither ERL nor ERR may apoear to the left of the = sign in a LET or assignment statement.
5) The RESUME statement. The RESUME statement is used to continue execution of the BASIC program after the error recovery procedure has been performed. The user has three options. The user may RESUME execution at the statement that caused the error, at the statement after the one that caused the error or at some other line. To RESUME execution at the statement which caused the error, the user should use:

RESUME
or
RESUME g
To RESUME execution at the statement immediately after the one which caused the error, the user should use:

RESUME NEXT
To RESUME execution at a line dfferent than the one where the error occurrea, use:

Where <line number> is not equal to zero.
6) Error Routine Example. The following example shows how a simple error trapping subroutine operates.

| 100 | ON ERROR GOTO 500 |
| :---: | :---: |
| 200 | INPUT "WHAT ARE THE NUMBERS TO DIVIDE";X,Y |
| 210 | $\mathrm{Z}=\mathrm{X} / \mathrm{Y}$ |
| 220 | PRINT "QUOTIENT IS";Z |
| 230 | GOTO 200 |
| 500 | IF ERR=11 AND ERL=210 THEN 520 |
| 510 | ON ERROR GOTO 0 |
| 520 | PRINT "YOU CANT HAVE A DIVISOR OF ZERO!" |
| 530 | RESUME 200 |

7) The ERROR statement. In order to force branching to an error trapping routine, an ERROR statement has been provided. The primary use of the ERROR statement is to allow the user to define his own error codes which can then conveniently be handled by a centralized error trap routine as described above. The format of the ERROR statement is:

ERROR <integer expression>
When defining error codes, values should be picked which are greater than the ones used by Altair BASIC. Since more error messages may be added to Altair BASIC, user-defined error codes should be assigned the highest available numbers to assure future compatibility. If the <numeric expression> used in an ERROR statement is less than zero or greater than 255 decimal, an ILLEGAL FUNCTION CALL error will occur. Of course, the ERROR statement may also be used to force SYNTAX or other standard Altair BASIC errors. Use of an ERROR statement to force printout of an error message for which no error text is defined will cause an UNPRINTABLE ERROR message to be printed out.

## 5-2. Extended Operators.

Two operators are provided that are exclusive to the Extended and Disk versions.
a. Integer Division. Integer division, denoted by \} (backslash), forces its arguments to integer form and truncates the quotient to an integer. More precisely:
$A \backslash B=F I X(\operatorname{INT}(A) / \operatorname{INT}(B))$

Its precedence is just after multiplication and floating point divison. Integer division is approximately eight times as fast as standard floating point division.
b. Modulus Arithmetic - the MOD operator. A MOD B gives the 'remainder' as A is divided by B. More precisely:
$A \operatorname{MOD} B=\operatorname{INT}(A)-(\operatorname{INT}(B) *(A \backslash B))$
If $B=\varnothing$, a DIVISION BY ZERO error occurs. The precedence of MOD is just below that of integer division.

## 5-3. Extended Functions.

a. Intrinsic Functions. Extended and Disk Altair BASIC provide several intrinsic functions which are not available in the other versions. For a list of these functions and $a$ description of their use, see section 6-3.
b. The DEFUSR statement. Up to ten assembly lanquage subroutines may be defined by means of the DEFUSR statement whose form is as follows:

DEFUSR[<digit 0 through 9>]=<integer expression>
Example:
DEFUSR1=\&I00000
DEFUSR2 $=31996$
DEFUSR9 $=$ ADR
The <integer expression> is the starting address of the USR routine specified. When the uSR subroutine is entered, the $A$ reqister contains the type of the argument which was given to the USR function. This is also the length of the descriptor for that argument type:

Value in A Meaning
2
3
4
8
Two byte signed two's complement inteaer. String.
Single precision four byte floating point number. Double precision floating point number.

When the USR subroutine is entered, the [H,L] reaister pair contains a pointer to the floating point accumulator (FAC). The [H,L] registers contain the address of FAC-3. If the value in the $F A C$ is a single precision floating point number, it is stored as follows:

FAC-3: Lowest 8 bits of mantissa. FAC-2: Middle 8 bits of mantissa.

FAC-1: Highest 7 bits of mantissa with hidden (implied)
leading one. Bit 7 is the sign of the number ( $\varnothing$ positive, 1 negative).
FAC: Exponent excess 200 octal. If the contents of $F A C$ is 200 , the exponent is 9 . If contents of $F A C$ is 9, the number is zero.

If the argument is double precision floating point, the FAC-7 to $F A C-4$ contain four more bytes of mantissa, low order byte in $F A C-7$, etc. If the argument is an integer, FAC-3 contains the low order byte and FAC-2 contains the high order byte of the signed two's complement value. If the arqument is a string, [D,E] points to a string descriptor of the argument, whose form is:

```
Byte Use
D Length of string 0-255 decimal.
1-2 Sixteen bit address pointer to first byte of
    strings text in memory (Caution - may point into
    program text if argument is a string literal).
```

The string returned by a call to USR with a string argument is the string the user's routine sets up in the descriptor. Modifying [D,E] does not affect the returned string. For example, $C \$=U S R(A \$)$ results in $C \$$ and $A \$$ being set to the same string. The statement $C \$=U S R(A S+"$ ") avoids modifying AS since the user's routine modifies the descriptor of the temporary string A\$+" ".

A string returned by the user's routine should lie withing the storage area occupied by the argument string. Increasing the length of a string in a user's routine is guaranteed to cause trouble.

Normally, the value returned by a USR function will be the same type (integer, string, single or double precision floating point) as the argument which was passed to it. However, calling the MAKINT routine whose address is stored in location 6 will return the integer in [H, [] as the value of the function, forcing the value returned by the function to be integer. Execute the following sequence to return from the function:

| PUSH | $H$ | ;SAVE VALUE TO BE RETURNED |
| :--- | :--- | :--- |
| LHLD | 6 | ;GET ADDRESS OF MARINT ROUTINE |
| XTHL |  |  |
|  |  |  |
| RET | ;GET BACK [H,L] |  |
|  |  | ;RETURN |

The argument of the function may be forced to an integer, no matter what its tyoe by calling the FRCINT routine whose
address is located in location 4 to get the integer value of the argument in [H,L]:

| LXI | H,SUBI | ;GET ADDRESS OF SUBROUTINE |
| :--- | :--- | :--- |
| PUSH | H | ;CONTINUATION |
| LHLD | 4 | ;PLACE ON STACK |
| PCHL |  | ;GET ADDRESS OF FRCINT |

SUB1:

5-4. The EDIT Command.
The EDIT command allows modifications and additions to be made to existing program lines without having to retype the entire line each time. Commands typed in the EDIT mode are, as a rule, not echoed. That is, they usually do not appear on the terminal screen or printout as they are typed. Most commands may be preceded by an optional numeric repetition factor which may be used to reoeat the command a number of times. This repetition factor should be in the range 0 to 255 ( $\theta$ is equivalent to 1 ). If the repetition factor is omitted, it is assumed to be l. In the following examples, a lower case " $n$ " before the command stands for the revetition factor. In the following description of the EDIT commands, the "cursor" refers to a pointer which is positioned at a character in the line being edited.

TO EDIT a line, tyoe EDIT followed by the number of the line and hit the carriage return. The line number of the line being EDITed will be printed followed by a space. The cursor will now be positioned to the left of the first character in the line.

## NOTE

The best way of getting the "feel" of the EDIT command is to try EDITing a few lines yourself.

If a command not recognized as an EDIT command is entered, the computer prints a beli (control/G) and the command is iqnored.

In the following examoles, the lines labelled "computer prints" show the apoearance of the line after each command.
a. Moving the Cursor. Typing a space moves the cursor to the right and causes the character oassed over to be printed. A number preceding the space (n<space>) will cause
the cursor to pass over and print out $n$ characters. Typing a Rubout causes the immediately previous character to be printed effectively backspacing the cursor.
b. Inserting Characters

WARNINGS:

Character insertion is stopped by tyoing Escape (or Altmode on some terminals). Control/C will not interrupt the EDIT command while it is in Insert mode, but will be inserted into the edited line. Therefore, Control/C should not be used in the EDIT command.

It is possible using EDIT to create a line which, when listed with its line number, is longer than 72 characters. Punched paper tapes containing such lines will not read properly. However, such lines may be CSAVEd and CLOADed without error.

I
Inserts new characters into the line being edited. Each character typed after the $I$ is inserted at the current cursor position and orinted on the terminal. Typing Escape (or Altmode on some terminals) stops character insertion. If an attempt is made to insert a character that will make the line longer than 255 characters, a Control/G (bell) is sent to the terminal and the character is not orinted.

A backarrow (or Rubout) typed during an insert command (or-) will delete the character to the left of the cursor. Characters up to the beginning of the line may be deleted in this manner, and a backarrow will be echoed for each character deleted. However, if there are no characters to the left of the cursor, a bell is echoed instead of a backarrow. If a carriage return is tyoed during an insert command, it is as if an escape and then carriage return were typed. That is, all characters to the right of the cursor will be printed and the EDITed line will reolace the original line.

X
$X$ is similar to $I$, except that all characters to the right of the cursor are printed, and the cursor moves to the end of the line. At this point, it will automatically enter the insert mode ( see I command). $X$ is most useful when new statements are to be added to the end of an existing line. For example:
User types EDIT 50 (carriage return)

Computer prints User types 50

Computer prints User types
$50 \quad x=x+1$
Computer prints
In the above example, the original line \#50 was:
50

$$
x=x+1
$$

The new line \#50 now reads:
50

$$
X=X+1: Y=Y+1
$$

$H$ is the same as $X$, except that all characters to the right of the cursor are deleted (they will not be printed). The insert mode (see $I$ command) will then automatically be entered. $H$ is most useful when the last statements on a line are to be raplaced with new ones.
c. Deleting Characters

D
nD deletes $n$ characters to the right of the cursor. If $n$ is ommitted, it defaults to 1 . If there are less than $n$ characters to the right of the cursor, characters will be deleted only to the end of the line. The cursor is positioned to the right of the last character deleted. The characters deleted are enclosed in backslashes (<br>). For example:

| er types | $20 \mathrm{X}=\mathrm{X}+1:$ REM JUST INCREMENT |
| :---: | :---: |
| User types | EDIT 20 (carriage return) |
| Computer prints | 20 |
| User types | 6D (carriaqe return) |
| Computer prints | $20 \backslash \mathrm{X}=\mathrm{X}+1: \ \mathrm{REM}$ JUST INCREMENT |

The new line 20 will no longer contain the characters which are enclosed by the backslashes.
d. Searching.

The nSy command searches for the nth occurrence of the character $y$ in the line. N defaults to l. The search skios over the first character to the riaht of the cursor and beqins with the second character to the right of the cursor. All characters passed over during the search are orinted. If the character is not found, the cursor will be at the end of the line. If it is found, the cursor will stop to the right of the character and all of the characters to its left
will have been printed. For example:
User types . 50 REM INCREMENT X
User types EDIT 50
Computer prints
User types
Computer prints

50
2SE
50 REM INCR
nKy is equivalent to $S$ except that all of the characters passed over during the search are deleted. The deleted characters are enclosed in backslashes. For example:

| User types | 10 TEST LINE |
| :--- | :--- |
| User types | EDIT I |
| Computer orints | 10 |
| User types | 10 KL |
| Computer prints | $10 \backslash T T$ |

e. Text Replacement.

C A character in line may be changed by the use of the command Cy which changes the character to the right of the cursor to the character $y$. $Y$ is printed on the terminal and the cursor is advanced one position. nCy may be used to change $n$ characters in a line as they are typed in from the terminal. (See example below.) If an attempt is made to change a character which does not exist, the change mode will be exited. Example:

| User types | 10 FOR $I=1$ TO 100 |
| :--- | :--- |
| User types | EDIT 10 |
| Computer orints | 10 |
| User types | 2SI |
| Computer orints | $I \emptyset$ FOR $I=1$ TO |
| User types |  |
| Computer prints | 10 FOR $I=1$ TO 256 |

f. Ending and Restarting

Carriage Return Terminates editing and prints the remainder of the line. The edited line replaces the original line.

E E is the same as a carriage return except the remainder of the line is not printed.

Q Q restores the original line and causes BASIC to return to command level. Changes do not take effect until an $E$ or carriage return is typed, so $Q$ allows the user to restore the original line without any
changes which may have been made.
L I causes the remainder of the line to be printed, and then prints the line number and restarts editing at the beginning of the line. The cursor will be positioned to the left of the first character in the line. L allows monitoring the effect of changes on a line. Example:

User types $\quad 50$ REM INCREMENT $X$
User types EDIT 50 Computer prints 50 User types Computer prints User types Computer prints50

## 2SM

50 REM INCRE
50 REM INCREMENT X 50

A
A causes the original line to be restored and editing to be restarted at the beginning of the line. For example:

| User types | 10 TEST LINE |
| :--- | :--- |
| User types | EDIT 10 |
| Computer prints | 10 |
| User types |  |
| Computer prints | $10 \backslash$ TEST LINE |
| User types |  |
| Computer prints | 10 |
|  | 10 |

Suppose in the above example, that the user made a mistake when he deleted TEST LINE. As a result of the A command, the original line 10 is reentered and is ready for further editing.

IMPORTANT
Whenever a SYNTAX ERROR is discovered during the execution of a source program , BASIC will automatically begin EDITing the line that caused the error as if an EDIT command had been typed. Example:

10 APPLE
RUN
SYNTAX ERROR IN 10
1D
Complete editing of a line causes the line edited to be reinserted. Reinserting a line causes all variable values to be deleted. To oreserve those values for examination, the EDIT command mode may be exited with the $Q$ command after the
line number is printed. If this is done, BASIC will return to command level and all variable values will be preserved.

The features of the EDIT command may be used on the line currently being typed. To do this, type Control/A instead of Carriage Return. The computer will respond with a carriage return, an exclamation point (!) and a space. The cursor will be positioned at the first character of the line. At this point, any of the EDIT subcommands except Control/A may be used to correct the line. Example:

User types
Computer prints User types
Computer prints

ID IF X GOTO \#"/A
!
S\# 2C12
! 10 IF X GOTO 12

The current line number may be designated by a period (.) in any command requiring a line number. Examples:

User types $\quad 10$ FOR $I=1$ TO 10
User types EDIT.
Computer prints 10

5-5. PRINT USING Statement.
The PRINT USING statement can be employed in situations where a specific output format is desired. This situation might be encountered in such applications as printing payroll checks or accounting reports. The general format for the PRINT USING statement is as follows:

PRINT USING <string>;<value list>
The <string> may be a string variable, string expression or a string constant which is a precise copy of the line to be printed. All of the characters in the string will be orinted just as they appear with the exception of the formatting characters. The <value list> is a list of the items to be orinted. The string will be repeatedly scanned until: 1) the string ends and there are no values in the value list or, 2) a field is scanned in the string, but the value list is exhausted. The string is constructed according to the following rules:
a. String Fields.
! specifies a single character string field. The string itself is specified in the value list.
\n spaces $\backslash$ specifies a string field consisting of $2+n$ characters. Backslashes with no spaces between them indicates a field 2 characters wide, one space between them indicates a field 3 characters wide, etc.

In both cases, if the string has more characters than the field width, the extra characters will be ignored. If the string has fewer characters than the field width, extra spaces will be orinted to fill out the entire field. Trying to orint a number in a string field will cause a TYPE MISMATCH error to occur. Examole:

$$
\begin{aligned}
& 10 \text { AS="ABCDE":BS="FGH" } \\
& 2 \emptyset \text { PRINT USING "!";AS;B\$ } \\
& 3 \emptyset \text { PRINT USING "\ } \ " ; B S ; A \$ \\
& \text { RUN }
\end{aligned}
$$

(the above prints out)

## AF

FGH ABCD
Note that where the "!" was used only the first letter of each string was printed. Where the backslashes enclosed two spaces, four letters from each strina were printed (an extra space was printed for $B S$ which has only three characters). The extra characters in the first case and for AS in the second case were ignored.
b. Numeric Fields. With the PRINT USING statement, numeric printouts may be altered to suit almost any application. Strings for formatting numeric fields are constructed from the following characters:
\#
Numeric fields are specified by the \# sign, each of which represents a diait position. These digit positions are always filled. The numeric field is right justified; that is, if the number printed is too small to fill all of the digit positions specified, leading spaces are printed as necessary to fill the entire field.

The decimal point may be specified in any position in the field. Rounding is performed as necessary. If the field format specifies that a digit is to orecede the decimal point, the digit is always printed (as 0 if necessary).

The following program will help illustrate these rules:

```
10 INPUT AS,A
20 PRINT USING AS;A
30 GOTO 10
RUN
? \#\#,12
    12
? \#\#\#,12
        12
? \#\#\#\#\#,12
12
?\#\#.\#\#,12
    12.90
? \#\#\#.,12
12.
? \#.\#\#\#,.02
    0.020
?\#\#.\#,2.36
2.4
?\#\#\#,-12
    -12
? \#.\#\#,-. 12
    -. 12
? \#\#\#\#,-12
    -12
```

end of the numeric field. If the number is positive,
the + sign is printed at the specified end of the
number. If the number is negative, a - sign is
printed at the specified end of the number.

- The - sign, when used to the right of the numeric field designation, forces the minus sign to be printed to the right of the number if it is negative. If the number is positive, a space is printed.

The ** placed at the beginning of a numeric field designation causes any unused spaces in the leading portion of the number printed out to be filled with asterisks. The ** also specifies Dositions for 2 more digits. (Termed "asterisk fill")

When the $\$ \$$ is used at the beginning of a numeric field desiqnation, a s sign is printed in the space immediately preceding the number printed. Note that \$\$ also specifies positions for two more digits, but that the $\$$ itself takes up one of these spaces. Exponential format cannot be used with leading \$ signs.
**\$ The **\$ used at the beginning of a numeric field designation causes both of the above (** and \$\$) to be performed on the number being printed out. All of the previous conditions apply, except that **\$ allows for 3 additional digit positions, one of which is the $\$$ sign.

A comma appearing to the left of the decimal point in a numeric field desianation causes a comma to be orinted to the left of every third digit to the left of the decimal point in the number being printed. The comma also specifies another digit position. A comma to the right of the decimal point in a numeric field designation is considered a part of the string itself and is treated as a printing character.
(Attt on some terminals) Exponential Format.
If exponential format is desired in the printout, the numeric field designation should be followed by (allows space for $E+X X$ ). Any decimal point arrangement is allowed. The significant digits are left justified and the exponent is adjusted. Unless a leading + or a trailing + or - is used, one position to the left of the decimal point is used to orint a space or minus sign. Examples:

```
PRINT USING "[##"-n"]"; 13,17,-8
    [ 1E+01][ 2E+01][-8E+00].
OK
PRINT USING "[.######"`~n-]; 12345,-123456
[.123450E+05 ][.123456E+06-]
OK
PRINT USING "[+.##"-"`]"; 123,-126
[+.12E+\emptyset3][-.13E+\emptyset3]
OK
```

If the number to be printed out is larger than the specified numeric field, a \% character is printed followed by the number itself in standard Altair BASIC format. (The entire number is printed.) If rounding a number causes it to exceed the specified field, the \% character is printed followed by the rounded number. If, for examole, $A=.999$, then
PRINT USING ".\#\#",A
prints

> \%1.0ø.

If the number of digits specified exceeds 24 , an ILLEGAL FUNCTION CALL error will occur.

The following program will help illustrate the preceding rules.

Program: 10 INPUT AS,A
$2 \emptyset$ PRINT USING AS;A
30 GOTO 10
RUN
The computer will start by typing a ?. The numeric field designator and value list are entered and the output is disolayed as follows:

```
? + \#, 9
\(+9\)
? + \#, 10

Typing Control／C will stop the program．
5－5．Disk File Operations．
As many as sixteen floppy disks may be connected to a single ALTAIR disk controller．These disks have been assigned the physical disk numbers 0 through 15．Jsers with one drive should address the arive at zero，and users with two drives
should address them at zero and one, etc.
In the following descriotions, <disk number> is an integer expression whose value is the physical number of one of the disks in the system. If the <disk number> is omitted from a statement other than MOUNT or UNLOAD, the <disk number> defaults to g. If the <disk number> is omitted from a MOUNT or UNLOAD statement, disks 0 through the highest disk number specified at initialization are affected.
a. Opening, Closing and Naming Files. To initialize disks for reading and writing, the the MOUNT command is issued as follows:

MOUNT [<disk number>[,<disk number>...]]
Example:
MOUNT Ø
mounts the disk on drive zero, and
MOUNT 0,1
mounts the disks on drives zero and one. If there is already a disk MOUNTed on the specified drive(s) a DISK ALREADY MOUNTED message will be printed. Before removing a disk which has been used for reading and writing by Disk Altair BASIC, the user should give an UNLOAD command:

UNLOAD [<disk number>[,<disk number>...]]
UNLOAD closes all the files open on a disk, and marks the disk as not mounted. Before any further $I / O$ is done on an UNLOADed disk, a MOUNT command must be given.

## NOTE

MOUNT, UNLOAD or any other disk command may be used as a program statement.

All data and program files on the disk have an associated file name. This name is the result of evaluating a string expression and must be one to eight characters in length. The first character of the file name cannot be a null.(g) byte or a byte of 255 decimal. An attempt to use a null file name (zero characters in length), a file name over 8 characters in length or containing $a$ or 255 in the first character
position will cause a BAD FILE NAME error. Any other sequence of one to eight characters is acceptable.

Examples of valid file names:
ABC
abc (Not the same as $A B C$ )
filename
file.ext
12345678
INVNTORY
FILE\#\#22

NOTE
Commands that require a file name will use <file name> in the appropriate position. Remember that a <file name> can be any string expression as long as the resulting string follows the rules given above.
b. The FILES Command. The FILES command is used to print out the names of the files residing on a particular disk. The format of the FILES command is:

FILES <disk number>
Example:
EILES
(prints directory of files on disk ())
STRTRK PIP CURFIT CISASM
Execution of the FILES command may be interrupted by typing Control/C. A more complete listing of the information stored in a particular file may be obtained by running the PIP utility program (see Apopendix I).
c. SAVEing and LOADing proarams. Once a program has been written, it is often desirable to save it on a disk for use at a later time. This is accomplished by issuing a SAVE command:

SAVE <file name>[,<disk number>[,A]]
Example:
SAVE "TEST", $\varnothing$

```
or
```

SAVE "TEST"
would save the program TEST on disk zero. Whenever a program is SAVEd, any existing copy of the program previously SAVEd will be deleted, and the disk space used by the previous program is made available. See section 5-6d for a discussion of saving with the 'A' option.

The LOAD statement reads a file from disk and loads it into memory. The syntax of the LOAD statement is:

LOAD <file name>[,<disk number>[,R]]
Correspondingly:
LOAD "TEST", 0 or LOAD "TEST"
loads the orogram TEST from disk zero. If the file does not exist, a FILE NOT FOUND error will occur.

LOAD "TEST". $\theta, R$
OK
LOADs the program TEST from disk zero and runs it. The LOAD command with the "R" option may be used to chain or segment programs into small pieces if the whole program is too large to fit in the computer's memory. All variables and program lines are deleted by LOAD, but all data files are kept OPEN(see below) if the "R" option is used. Therefore, information may be passed between programs through the use of disk data files. If the "R" ootion is not used, all files are automatically CLOSEd (see below) by a LOAD.

Example:

## NETH

10 PRINT "FOO1":LOAD "FOO2", $0, R$ SAVE "FOOI",

OK
10 PRINT "FOO2":LOAD "FOO1", $0, R$
SAVE "FOO2". 0
OK
RUN
FOO2
FOOI
FOO2

FOO1
...etc.
(Control/C may be used to stop execution at this point)

In this examole, program FOO2 is RUN. FOO2 prints the message "FOO2" and then calls the program FOOl on disk. FOOI prints "FOO1" and calls the program FOO2 which prints "FOO2" and so on indefinitely.

RUN may also be used with a file name to load and run a program. The format of the command is as follows:

RUN<file name>[,<disk number>[,R]]
All files are closed unless,$R$ is specified after the disk number.
d. SAVEing and LOADing Program Files in ASCII. Often it is desirable to save a program in a form that allows the program text to be read as data by another program, such as a text editor or resequencing program. Unless otherwise specified, Altair BASIC saves its orograms in a compressed binary format which takes a minimum of disk space and loads very quickly. To save a program in ASCII, specify the "A" option on the SAVE command:

```
SAVE "TEST",0,A
```

OK
LOAD "TEST", $\emptyset$
OK

Information in the file tells the LOAD command the format in which the file is to be loaded. The first character of an ASCII file is never 255, and a binary program file always starts with 255 ( 377 octal). Remember, loading an ASCII file is much slower than loading a binary file.
e. The MERGE Command. Sometimes it is very useful to put parts of two programs together to form a new program combining elements of both programs. The MERGE command is provided for this purpose. As soon as the MERGE command has been executed, BASIC returns to command level. Therefore, it is more likely that MERGE would be used as a direct command than as a statement in a program. The format of the MERGE
statement is as follows:
MERGE <file name>[,<disk number>]
Example:
MERGE "PRINTSUB",1 OK

The <file name> specified is merged into the program already in memory. The <file name> must soecify an ASCII format saved program or a BAD FILE MODE e $\overline{r r O r}$ will occur. If there are lines in the program on disk which have the same line numbers as lines in the program in memory, the lines from the file on disk will replace the corresponding program lines in memory. It is as if the program lines of the file on disk were typed on the user terminal.
f. Deleting Disk Files. The KILL statement deletes a file from disk and returns disk space used by the file to free disk space. The format of the KILL statement is as follows:

KILL <file name>[,<disk number>]
If the file does not exist, a FILE NOT FOUND error will occur. If a KILL statement is given for a file that is currently OPEN (see below), a FILE ALREADY OPEN error occurs.
g. Renaming Files - the NAME Statement. The NAME statement is used to change the name of a file:

NAME <old file name> AS <new file name>[,<disk number>]
Example:
NAME "OLDFILE" AS "NEWFILE"
The <old file name> must exist, or a FILE NOT FOUND error will occur. A file with the same name as <new file name> must not exist or a FILE ALREADY EXISTS error will occur. After the NAME statement is executed, the file exists on the same disk in the same area of disk space. Only the name is changed.
h. OpENing Data Files. Before a orogram can read or write data to a disk file, it must first OPEN the file on the approcriate disk in one of several modes. The general form of the OPEN statement is:

OPEN <mode>, [\#]<file number>, <file name>[,<disk number>]
<mode> is a string expression whose first character is one of the following:

| 0 | Specifies sequential output mode |
| :--- | :--- |
| I | Specifies sequential input mode |
| R | Specifies random Input/Output mode |

A sequential file is a stream of characters that is read or written in order much like INPUT and PRINT statements read from and write to the terminal. Random files are divided into groups of 128 characters called records. The nth record of a file may be read or written at any time. Random files have other attributes that will be discussed later in more detail.
<file number> is an integer expression between one and fifteen. The number is associated with the file being OPENed and is used to refer to the file in later $I / O$ operations.

Examples:
OPEN "O",2,"OUTPUT", 0
OPEN "I",1,"INPUT"
The above two statements ooen the file OUTPUT for sequential output and the file INPUT for sequential input on disk zero. The following statement opens the file whose name is in the string F \$ in mode $\mathrm{M} \$$ as file number N on disk D .

OPEN MS,N,FS,D
i. Sequential ASCII file $I / O$ Sequential input and output files are the simplest form of disk input and output since they involve the use of the INPUT and PRINT statements with a file that has been previously OPENed.

1) INPUT is used to read data from a disk file as follows:

INPUT \#<file number>,<variable list>
where <file number> represents the number of the file that was OPENed for input and <variable list> is a list of the variables to be read, as in a normal INPUT statement. When data is read from a sequential input file using an INPUT statement, no question mark (?) is printed on the terminal. The format of data in the file should appear exactly as it would be typed to a standard INPUT statement to the terminal.

When reading numeric values, leading spaces, carriage returns and line feeds are ignored. When a non-space, non-carriage return, non-line-feed character is found, it is assumed to be part of a number in Altair BASIC format. The number terminates on a space, a carriage return, line-feed or a comma.

Leading blanks, carriage returns and line-feeds are also ignored when scanning for string items. When a character which is not a leading blank, carriage return or line-feed is found, it is assumed to be the start of a string item.If this first character is a quotation mark ("), the item is taken as being a quoted string, and all characters between the first quotation mark (") and a matching quotation mark are returned as characters in the string value. This means that a quoted string in a file may contain any characters exceot double quote. If the first character of a string item is not a quotation mark, then it is assumed to be an unquoted string constant. The string returned will terminate on a comma, carriage return or line feed. The string is immediately terminated after 255 characters have been read.

For both numeric and string items, if end of file (EOF) is reached when the item is being INPUT, the item is terminated regardless of whether or not a closing guote was seen.

Sequential I/O commands destroy the input buffer so they may not be edited by Control/A for re-execution.

Example of sequential $1 / O$ (numeric items):

5のの OPEN "O", 1,"FILE", $\varnothing$
510 PRINT \#1,X,Y,Z
520 CLOSE 1
530 OPEN "I", !,"FIIE", 0
540 INPUT \#1", X,Y,Z
Note that CLOSE is used so that a file which has just been written may be read. When FILE is re-OPENed, the data pointer for that file is set back to the beginning of the file so that the first INPUT on the file will read data from the start of the file.
2) PRINT and PRINT USING statements are used to write data into a sequential output file. Their formats are as follows:

PRINT \#<file number>,<expression list>
or

```
PRINT #<file number>, <line feed
USING <string expression>;<expression list>
Example of sequential I/O (quoted string items):
```

500 OPEN "O", I,"FILE"
510 PRINT \#I,CHR\$(34);X\$;CHR\$(34);
515 PRINT \#1,CHRS (34);Y\$;CHR\$(34);CHR\$(34);2\$;CHR\$(34)
520 CLOSE 1
530 OPEN "I", I,"FILE",
540 INPUT \#1,X\$,Y\$,Z\$

In this example, the strings being output (XS, Y\$, $Z \$$ ) are surcounded with double quotes through the use of the chrs function to generate the ASCII value for a double quote. This technique must be used if a string which is being output to a sequential data file contains commas, carriage returns, line-feeds or leading blanks that are significant. When leading blanks are not significant and there are no commas, carriage returns or line-feeds in the strings to be output, it is sufficient to insert commas between the strings being output as in the following example:

```
500 OPEN "O",1,"FILE"
510 PRINT #l,X$;",";Y$;",";Z$
520 CLOSE 1
530 OPEN "I",I,'EILE",g
540 INPUT #1,X$,Y$,Z$
```

3) CLOSE. The format of the CLOSE statement is as follows:

CLOSE [<file number>[,<file number>...]]
CLOSE is used to finish I/O to a particular Altair BASIC data file. After CLOSE has been executed for a file, the file may be reopened for input or output on the same or different <file number>. A CLOSE for a secuential output file writes the final buffer of output. A CLOSE to any OPEN file finishes the connection between the <file number> and the <file name> given in the OPEN for that file. It allows the <file number to be used again in another OPEN statement.

A CLOSE with no argument CLOSEs all OPEN files.

A FILE can be OPENed for sequential input or random access on more than one <file number> at a time but may be OPEN for output on only one <file number> at a time.

END and NEW always CLOSE all disk files automatically. STOP does not CLOSE disk files.
4) LINE INPUT. It is often desirable to read a whole line of a file into a string without using quotes, commas or other characters as delimiters. This is especially true if certain fields of each line are being used to contain data items, or if a BASIC program saved in ASCII mode is being read as data by another program. The facility provided to perform this function is the LINE INPUT statement:

LINE INPUT \#<file number>,<string variable>
A LINE INPUT from a data file will return all characters up to a carriage return in <string variable>. LINE INPUT then skips over the following carriage return/line-feed sequence so that a subsequent LINE INPUT from the file will return the next line.
5) End of File (EOF) Detection. When reading a sequential data file with INPUT statements, it is usually desirable to detect when there is no more data in the disk file. The mechanism for detecting this condition is the EOF function:

$$
X=E O F(\langle f i l e \text { number }\rangle)
$$

EOF returns TRUE ( -1 ) when there is no more data in the file and FALSE ( $\varnothing$ ) otherwise. If an attempt is made to INPUT past the end of a data file, an INPUT PAST END error will occur.

Example:

```
10\emptyset OPEN "I",I,"DATA",\emptyset
110 I=\emptyset
120 IF EOF(1) THEN 160
130 INPUT #1,A(I)
140 I=I+1
150 GOTO 120
160 ......
```

In this example, numeric data from the sequential inout file DATA is read into the array $A$. When end of file is detected, the IF statement at line 120 branches to line 160 , and the variable I "points" one beyond the last element of $A$ that was INPUT from the file.

The following is a program that will calculate the number of lines in a BASIC program file that has been SAVEd in ASCII mode:

This example uses the LINE INPUT statement to read each line of the program into the "dummy" string L\$ which is used just to INPUT and ignore that part of the file.
6) Finding the Amount of Free Disk Space (DSKF). It is sometimes necessary to determine the amount of free disk space remaining on a particular disk before writing a file. The DSKF function provides the user with the number of free groups left on a given disk after the disk has been MOUNTed. A group is the fundamental unit of file allocation. That is, files are always allocated in groups of eight sectors at a time. Each sector contains 128 characters (bytes). Therefore, the minimum size for a file is 1024 bytes.

Syntax for the DSKF function:
DSKF (<đisk number>)
Example:
PRINT DSKF(Ø)
200
The above example shows that there are $200 * 1924=204300$ characters (bytes) that can still be stored on disk zero.
j. RANDOM FILE I/O. Previously, we have discussed how data may be PRINTed or INPUT from sequential data files. However, it is often desirable to access data in a random fashion, for instance, to retrieve information on a particular part number or customer from a large data base stored on a floppy disk. If sequential files were used, the whole file would have to be scanned from the start until the particular item was found. Random files remove this restriction and allow a program to access any record from the first to the last in a speedy fashion. Also, random files transfer data from variables to the disk ouput records and vice versa in a much faster, more efficient fashion than sequential files.

Random file $I / O$ is more complex than sequential $I / O$, and it is recommended that beginners try sequential I/O first.

1) OPENing a FILE for Random I/O. Random I/O files are OPENed just like sequential files.

$$
\text { OPEN "R",1,"RANDOM", } \varnothing
$$

When a file is OPENed for random $I / O$, it is always OPEN for both input and output simultaneously.
2) CLOSING Random Files. Like sequential files, random files must be closed when I/O operations are finished. To CLOSE a random file, use the CLOSE command as described previously.

CLOSE <file number>[,<file number>...]
3) Reading and writing data to a random file - GET and PUT. Each random file has associated with it a "random buffer" of 128 bytes. When a GET or PUT operation is performed, data is transferred directly from the buffer to the data file or from the data file to the buffer. The syntax of GET and PUT is as follows:

PUT [\#]<file number>[,<record number>]
GET [\#]<file number>[,<record number>]
If <record number> is omitted from a GET or PUT statement, the record number that is one higher than the previous GET or PUT is read into the random buffer. Initially a GET or PUT without a record number will read or write the first record. The largest possible record number is 2046 . If an attempt is made to GET a record which has never been PUT, all zeroes are read into the record, and no error occurs.
4) LOC and LOF. LOC is used to determine what the current record number is for random files. In other words, it returns the record number that will be used if a GET or PUT is executed with the <record number> parameter omitted.

```
LOC(<file number>)
```

PRINT LOC (1)
15

LOC is also valid for sequential files, and gives the number of sectors (l28 byte blocks) read or written since the OPEN statement was executed.

LOF is used to determine the last record number written to a random file:

LOF (<file number>)
PRINT LOF (2) 200

An attempt to use LOF on a sequential file will cause a BAD FILE MODE error.

The value returned by LOF is always 5 MOD 8. That is , when the value LOF returns is divided by 8 , the remainder is always 5. Therefore,the values returned by LOF are 5, 13, 21, 29 etc. This is due to the way random files are allocated.

NOTE
It is important to note that the value returned by LOF may be a record that has never been written in by a user program. This is because of the way random files are pre-extended.
5) Moving Data In and Out of the Random Buffer. So far we have described techniques for writing (PUT) and reading (GET) data from a file into its associated random buffer. Now we will describe how data from string variables is moved to and from the ranaom buffer itself. This is accomplished through the use of the FIELD, LSET and RSET statements.
6) FIELD. The FIELD statement associates some or all of a file's random buffer with a particular string variable. Then, when the file buffer is read with GET or written with PUT, string variables which have been FIELDed into the buffer will automatically have their contents read or written. The
format of the FIELD statement is:
EIELD [\#] <file number>,<field size> AS <string variable>[...]
<file number> is used to specify the file number of the file whose random buffer is being referenced. If the file is not a random file, a BAD FILE MODE error will occur. <field size> sets the length of the string in the random buffer. <string variable> is the string variable which is associated with a certain number of characters (bytes) in the buffer. Multiple fields may be associated with string variables in a given FIELD statement. Each successive string variable is assigned a successive field in the random buffer. Examole:

$$
\text { FIELD } 10 \text { AS A } \$ 20 \text { AS B } \$, 3 \emptyset \text { AS } C \$
$$

The statement above would assign the first lo characters of the random buffer to the string variable As, the next 20 characters to $B \$$ and the next 30 characters to the variable C\$. It is important to note that the FIELD statement does not cause any data to be transferred to or from the random buffer. It only causes the string variables given as arguments to "point" into the random buffer.

Often, it is necessary to divide the random buffer into a number of sub-records to make more efficient use of disk space. For instance, it might be desirable to divide the 128 character record into two identical subrecords. To accomplish this a "dummy variable" would be placed in the FIELD statement to represent one of the subrecords. One of the following statements would be executed, depending on whether the first or second subrecord were needed:

FIELD \#1,64 AS D\$, 20 AS NAME\$,
20 AS ADDRESSES, 24 AS OCCUPATIONS
or
FIELD \#1,20 AS NAMES, 20 AS ADDRESSES, 24 AS OCCUPATION\$, 64 AS D\$
where the dummy variable D S is used to skip over one of the subrecords. Another way to do the same thing would be to set a variable I that would select the first or second subrecord:

FIELD \#1,64*(I-1) AS DS,
$2 \emptyset$ AS NAMES, $2 \emptyset$ AS ADDRESS\$, 24 AS OCCUPATION\$
Here, if the variable $I$ is one, $I-1 * 64=0$ characters will be skipped over, selecting the first subrecord. If I is two, 64 characters will be skioped over, selecting the second
subrecord. Another useful technique is to use a FOR...NEXT loop and an array to set up subrecords in the random buffer:

```
1000 FOR I=1 TO 16
1010 FIELD #1, (I-1)*8 AS D$, 4 AS AS(I),
    4 AS B$(I)
1020 NEXT I
```

In this example, we have divided the random buffer into 16 subrecords composed of two fields each. The first 4-character field is in $A \$(X) X$ is the subrecord number.

NOTE
The FIELD statement may be executed any number of times on a given file. It does not cause any allocation of string space. The only space allocation that occurs is for the string variables mentioned in the FIELD statement. These string variables have a one byte count and two byte pointer set up which points into the random buffer for the specified file.
7) Using Numeric Values in Random Files: MKIS, MKS\$, MKDS and CVI, CVS, CVD. As we have seen, data is always stored in the random buffer through the use of string variables. In order to convert between strings and numbers and vice versa, a number of special functions have been provided.

To convert between numbers and strings:

| MKIS(<integer value>) | Returns a two byte string (FC ercor if value is not $>=-32768$ and $<=+32757$. <br> Fractional part is lost) |
| :---: | :---: |
| MKS\$ (<single precision value>) | Returns a four byte string |
| MKD\$ (<double orecision value>) | Returns an eight byte string |
| To convert between strings and numbers: |  |
| CVI(<two byte string>) | Returns an integer value |
| CVS(<four byte string>) | Returns a single precision value |
| CVD(<eight byte string>) | Returns a double precision value |

CVI, CVS, and CVD all give an ILLEGAI FUNCTION CALL ercor if
the string given as the argument is shorter than required. If the string argument is longer than necessary, the extra characters are ignored. These functions are extremely fast since they convert between Altair BASIC's internal representations of integers, single and double precision values and strings. Conventional sequential I/O must perform time-consuming character scanning algorithms when converting between numbers and strings.
8) LSET and RSET. When a GET operation is performed, all string variables which have been FIELDed into the random buffer for that file automatically have values assigned to them. The CVI, CVS and CVD functions may be used to convert any numeric fields in the record to their numeric values. When going the other way, i.e. inserting strings into the random buffer before performing a PUT statement, a problem arises. This is because of the way string assignments usually take place. For example:

$$
\text { LET } A \$=B \$
$$

When a LET statement is executed, $3 \$$ is copied into string space, A\$ is pointed to the new string and the string length of A\$ is modified. However, for assignments into the random buffers we do not want this to happen. Instead, we want the string being assigned to be stored where the string variable was FIELDed. In order to do this, two special assignment statements have been provided, LSET and RSET:

LSET <string variable>=<string expression>
RSET <string variable>=<string expression>
Examples:
LSET A\$=MKS\$ (V)
RSET B\$="TEST"
LSET CS (I) =MKD\$ (D
The difference between LSET and RSET concerns what happens if the string value being assigned is shorter than the length soecified for the string variable in the EIELD statement. LSET. left justifies the string, adding blanks (octal 40, decimal 32) to pad out the right side of the string if it is too short. RSET right justifies the string, padding on the left. If the string value is too long, the extra characters at the end of the string are ignored.

Do not use LSET or RSET on string variables which have not been mentioned in a FIELD statement, or a SET TO NON DISK STRING error will occur.
k. The DSKIS and DSKO\$ Primitives. Often it is necessary for the user to perform disk I/O operations directly without using any of the normal file structure features of Altair BASIC. To allow this, two special functions have been provided. These are the DSKIS function and the DSKOS statement. First, examples will be provided on how to perform simple disk I/O commands using Altair BASIC statements.

To Enable disk $0:$
OUT 8,0
To Enable disk $N:$
OUT 8,N
TO step the disk head out one track:
WAIT 8,2,2:OUT 9,2
To step the disk head in one track:
WAIT 8,2,2:OUT 9,1
To test for track $\varnothing$ :
IF (INP (8) AND 64) $=\emptyset$ THEN <statements or line number>
The above will execute the statements or branch to the line number if the head is positioned at track 0 . This is the outermost track on the disk.

To read sector $Y$ ( $Y$ may be any expression, minimum sector $=0$, maximum $=31$ ):

$$
A \$=D S K I \$(Y)
$$

The statement
DSKOS <string expression>,<sector expression>
writes the string expression on the sector specified. The high order bit (most signifigant) of the first character output will always be set to one when the string is written on the sector and will always be one when the sector is read back in using DSKIS. A maximum of 137 characters are written; giving a string whose length exceeds 137 characters will cause an ILLEGAL FUNCTION CALL error. If the string argument is less than 137 characters in length, the end of the string will be padded with zeros to make a string of length 137.
6. LISTS AND DIRECTORIES

6-1. Commanãs.

Commands airect Altair BASIC to arrange memory and input/output facilities, to list and edit programs and to handle other housekeeping details in support of program execution. Altair BASIC accepts commanas after it prints ${ }^{\prime}$ OK' and is at command level. The table below lists the commands in alphabetical order. The notation to the right of the command name indicates the versions to which it applies.

Command
Version(s)
CLEAR
All
Sets all program variables to zero.
CLEAR[<expression>] 8K, Extended, Disk
Same as CLEAR but sets string space to the value of the expression. If no argument is given, string space will remain unchanged. When Altair BASIC is loaded, string space is set to 50 bytes in 8 K and 200 bytes in Extended and Disk.

CLOAD<string expression> 8K(cassette), Extended, Disk
Causes the program on cassette tape designated by the first character of STRING expression> to be loaded into memory. A NEW command is issued before the program is loaded.

CLOAD*<array name> 8K(cassette), Disk
Loads the specified array from cassette tape. May be used as a program statement.

CLOAD?<string expression> 8K(cassette), Extended, Disk
Compares the program in memory with the corresponding file on cassette tape. If the files are the same, CLOAD? prints OK. If not, it prints NO GOOD. The <string expression> must be given, but it is ignored.

CONT
8K, Extended, Disk
Continues program execution after a Control/C has been typed or a STOP or END statement has been executed. Execution resumes at the statement after the break occurred unless input from the terminal was interrupted. In that case, execution resumes with the reprinting of the prompt (? or prompt string). CONT is useful in debugging, especially where an
'infinite loop' is suspected. An infinite loop is a series of statements from which there is no escape. Typing control/C causes a break in execution and puts BASIC in command level. Direct mode statements can then be used to print intermediate values, change the values of variables, etc. Execution can be restarted by typing the CONT command, or by executing a direct mode GOTO statement, which causes execution to resume at the specified line number.

In 4 K and 8 K Altair BASIC, execution cannot be continued if a direct mode error has occured during the break. In all versions, execution cannot continue if the program was modified during the break.

CSAVE<string expression> 8K(cassette), Extended, Disk
Causes the program currently in memory to be saved on cassette tape under the name specified by the first character of <string expression>.

CSAVE*<array name> 8K(cassette), Disk
Causes the array named to be saved on cassette tape. May be usea as a program statement.

DELETE<line number> Extended, Disk
Deletes the line in the current program with the specified number. If no such line exists, an ILLEGAL FUNCTION CALL error occurs.

DELETE-<line number> Extended, Disk
Deletes every line of the current program up to and including the specified line. If there is no such line, an ILLEGAL FUNCTION CALL error occurs.

DELETE<line number>-<line number> Extended, Disk
Deletes all lines of the current program from the first line number to the second inclusive. ILLEGAL FUNCTION CALL occurs if no line has the second number.

DSKINI<drive number> Disk
Initializes diskettes on the specified drives by marking all sectors in tracks $6-77$ as free. If no disk number is given, all disks are initialized beginning with the highest disk number. CAUTION: DSKINI destroys all files on the disk. Use with utmost caution.

EDIT<line number>
Extended, Disk

Allows editing of the line specified without affecting any other lines. The EDIT command has a powerful set of sub-commands which are discussed in detail in section 5-4.

LIST
All
Lists the program currently in memory, starting with the lowest numbered line. Listing is terminated either by the end of the program or by typing Control/C.

The LIST command may be used to save programs on paper tape. Simply type LIST and turn on the teletype's paper tape punch before typing carriage return. Be sure the nulls have been set (see NULL command) to 3 before punching the program. To load a program from paper tape, put the tape in the teletype's reader and turn it on. The program loads as if it were being typed from the terminal. The NEW command may be used to clear old program lines before loading the new program.

LIST[<line number>] All
In 4 K and 8 K , prints the current program beginning at the specified line. In Extended and Disk, prints the specified line if it exists.

LIST[<line number>][-<line number>] Extended, Disk
Allows several listing options.

1. If the second number is omitted, lists all lines with numbers greater than or equal to the number specified.
2. If the first number is omitted, lists all lines from the beginning of the program to the specified line, inclusive.
3. If both line numbers are used, lists all lines from the first number to the second, inclusive.

LLIST[<line number>][-<iine number>] Extended, Disk
Same as list with the same options, except prints on the line printer.

NEW
All
Deletes the current program and clears all variables. Used before entering a new program.

NULL<integer expression>
8K, Extended, Disk

Sets the number of nulls to be printed at the end of each line. For 10 or 30 character per second tape punches, <integer expression> should be >=3. When tapes are not being punched, <integer expression> should be $\emptyset$ or 1 for Teletypes* and Teletype compatible CRT's. It should be 2 or 3 for 30 cps hard copy printers. The default value is 0 . In the 4 K version, the same affect may be achieved by patching location 46 octal to contain the number of nulls plus 1.

* Teletype is a registered trademark of the Teletype Corporation.

RUN [<line number>]
All
Starts execution of the program currently in memory at the line specified. If the line number is omitted, execution begins at the lowest line number. Line number specification is not allowed in 4 K .

## 6-2. Statements.

The following table of statements is listed in alpahabetical order. The notation in the Version column designates the versions to which each statement applies. In the table, $x$ and $y$ stand for any expressions allowed in the version under consideration. I and $J$ stand for expressions whose values are truncated to integers. $V$ and $w$ are any variable names. The format for an Altair BASIC line is as follows:

```
<nnnnn> <statement>[:<statement>...]
```

where nnnnn is the line number.

expressions．List elements are separated by commas．
DEF $\quad \operatorname{DEF} \operatorname{FNV}(\langle\mathcal{W}\rangle)=\langle X\rangle \quad$ 8K，Extended，Disk
Defines a user－defined function．Function name is FN followed by a legal variable name．Extended and Disk versions allow user－defined string functions．Definitions are restricted to one line（ 72 characters in 4 K and $8 \mathrm{~K}, 255$ characters in extended versions）．

DEFUSR DEFUSR［〈aigit＞］＝〈X＞Extended，Disk
Defines starting adaress of assembly language subroutine．Up to ten subroutines are allowed．

DIM $\operatorname{DIM}\langle V\rangle(\langle I\rangle[, J . .]).[, \ldots]$ All

Allocates space for array variables．In $4 K$ ，only one dimension is allowed per variable．More than one variable may be dimensioned by one DIM statement up to the limit of the line．The value of each expression gives the maximum subscript possible．The smallest subscript is 0．Without a DIM statement，an array is assumed to have maximum subscript of 10 for each dimension referenced．For example，$A(I, J)$ is assumed to have 121 elements，from $A(0,0)$ to $A(10,10)$ unless otherwise dimensioned in a DIM statement．

END
END
All
Terminates execution of a program．Closes all files in the Disk version．

ERASE ERASE〈V＞［，〈W〉．．．］Extended，Disk
Eliminates the arrays specified．The arrays may be redimensioned or the space made available for other uses．

ERROR ERROR〈I＞Extended，Disk
Forces error with code specified by the expression．used primarily for user－defined error codes．

Allows repeated execution of the same statements．First execution sets $V=X$ ．Execution proceeds normally until NEXT is encountered．$Z$ is adaed to $V$ ，then，$I F Z<\theta$ and $V>=Y$ ，or if $Z>\emptyset$ and $V<=Y$, BASIC branches back to the statement after FOR． Otherwise，execution continues with the statement after NEXT．

GOTO
GOTO＜nnnnn＞
A11
Unconditional branch to line number．
GOSUB
GOSUB＜nnnnn＞
All
Unconditional branch to subroutine beginning at line nnnnn．
IF．．．GOTO IF 〈X＞GOTO＜nnnnn＞8K，Extended，Disk
Same as IF．．．THEN except GOTO can only be followed by a line number and not another statement．

```
IF...THEN [ELSE] IF<X>THEN<Y>[ELSE<Z>] All
    or IF<X>THEN<statement>[:statement...]
    [ELSE<statement>[:statement...]
```

If vaiue of $X<>\emptyset$ ，branches to line number or statement after THEN．Otherwise，branches to the line number or statement（s） after ELSE．If ELSE is omitted，and the value of $X=0$ ， execution proceeds at the line after the IF．．．THEN．In $4 \mathrm{~K}, \mathrm{X}$ can only be a numeric expression．The ELSE clause is only allowed in Extended and Disk Altair BASIC．

INPUT INPUT $\langle V\rangle[,\langle W\rangle \ldots]$ All
Causes BASIC to request input from terminal．Values（or，in 4 K ，expressions）typed on the terminal are assigned to the variables in the list．

LET
LET 〈V〉＝〈X＞
All
Assigns the value of the expression to the variable．The word LET is optional．

LINE INPUT LINE ：INPUT［－prompt stringi；］＜line feed＞ ＜string variable name＞Extended，Disk

LINE INPUT prints the prompt string on the terminal and assigns all input from the end of the prompt string to the carriage return to the named string variable．No other prompt is printed if the prompt string is qmitted．LINE INPUT may not be edited by Control／A．

LPRINT LPRINT X［，Y．．．］Extended，Disk
Same as PRINT，but prints on the line printer．Line feeds within strings are ignored．A carriage return is printed automatically after the 80 th character on a line．

LPRINT USING LPRINT USING＜string＞；＜list＞Extended，Disk
Same as PRINT USING but prints on the line printer．For a detailed description，see section 5－5．
$\operatorname{MIDS} \quad \operatorname{MID}(\langle X \$\rangle,\langle I\rangle[,\langle J\rangle])=Y \$$ Extended，Disk
Part of the string $X \$$ is replaced by $Y \$$ ．Replacement starts with the Ith character of $X \$$ and proceeds until $Y \$$ is exhausted，the end of $X \$$ is reached or $J$ characters have been replaced，whichever comes first．If I is greater than LEN（XS），an ILLEGAL FUNCTION CALL error results．

NEXT NEXT $[\langle V\rangle,\langle W\rangle \ldots]$ All
Last statement of a $F$ FOR loop．$V$ is the variable of the most recent loop，$W$ of the next most recent and so on．Only one variable is allowed in 4 K ．Except in 4 K ，NEXT without a variable terminates the most recent FOR loop．

ON ERROR GOTO ON ERROR GOTO＜line number＞Extended，Disk
When an error occurs，branches to line specified．Sets variable ERR to error code and ERL to line number where the error occured．See section 6－5 for a list of error codes．ON ERROR GOTO $\emptyset$（or without number）disables error trapping．

ON．．．GOTO ON＜I＞GOTO＜list of line numbers＞ 8 K ，Ext．，Disk
Branches to line whose number is Ith in the list．List elements are separated by commas．if $I=0$ or $>$ number of elements in the list，execution continues at next statement． If i＜0 or＞255，an error results．

ON．．．GOSUB ON＜I＞GOSUB＜list＞8K，Extended，Disk
Same as ON．．．GOTO except list elements are initial line numbers of subroutines．

OUT OUT＜I＞，〈J〉 8K，Extended，Disk
Sends byte $J$ to port I．$\quad \emptyset<=I, J<=255$ ．
POKE
POKE〈I〉，＜J〉
8K，Extended，Disk
Stores byte $J$ in memory location derived from I．
$\emptyset<=J<=255 ;-32768<I<65536 . \quad$ If $I$ is negative, address is $65536+$ I. If I is positive, address=I.

PRINT $\operatorname{PRINT}\langle X\rangle[,\langle Y\rangle \ldots]$ All
Causes values of expressions in the list to be printed on the terminal. Spacing is determined by punctuation.

Punctuation Spacing - next printing begins: at beginning of next 14 column zone
; other or none at beginning of next line
String literals may be printed if enclosed by quotation marks ('1). String expressions may be printed in all but 4 K .

PRINT USING PRINT USING<string>; <list> Extencied, Disk
Prints the values of the expressions in the list edited according to the string. The string is an expression which represents the line to be printed. The list contains the constants, variable names or expressions to be printed. List entries are separated by punctuation as in the PRINT statement. For a list of string characters and their functions, see section 5-5.

READ
$\operatorname{READ}\langle\mathrm{V}\rangle$ [,<W〉...]
All
Assigns values in DATA statements to variables. Values are assigned in sequence starting with the first value in the first DATA statement.

REM
REM [<remark>]
A11
Allows insertion of remarks. Not executed, but may be branched into. In Extended and Disk versions, remarks may be added to the end of a line preceded by a single quotation mark ( ${ }^{\prime}$ )

RESTORE RESTORE All
Allows data from DATA statements to be reread. Next READ statement after RESTORE begins with first data of first data statement.

RESUME RESUME[<number>] Extended, Disk
Resumes program execution at the line specified after error trapping routine. If number is omitted or zero, resumes at statement where error occured. RESUME NEXT causes resumption at the statement following the statement where the error was made.

RETURN RETURN AII
Terminates a subroutine. Branches to the statement after the most recent GOSUB.

STOP STOP . All
Stops program execution. BASIC enters command level and, except in $4 K$, prints BREAK IN LINE nnnnn. Unlike END, STOP does not close files.

SWAP SWAP $\langle V\rangle,\langle W\rangle$ Extended, Disk
Exchanges values of the variables named. Variables must be of the same type.

TROFF TROFF Extended, Disk
Turns off trace flag. The trace flag is turned on by TRON (see below). NEW also turns off the trace flag.

TRON TRON Extended, Disk
Turns on trace flag. Prints number of each line in square brackets as it is executed.

WAIT WAIT〈I>, $\langle J\rangle[,\langle K\rangle] \quad 8 K$, Extended, Disk
Status of port I is XOR'd with $K$ and AND'ed with J. Continued execution awaits non-zero result. $K$ defaults to $\quad$. $\emptyset<=I, J, K<=255$.

## 6-3. Intrinsic Functions.

Altair BASIC provides several commonly used algebraic and string functions which may be called from any program without further definition. If the functions are not required for a program, they may be deleted when BASIC is loaded to conserve memory space. The functions in the following table are listed in alphabetical order. The notation to the right of the call Format is the version(s) in which the function is available. As usual, $X$ and $Y$ stand for expressions, $I$ and $J$ for integer expressions and $X \$$ and $Y \$$ for string expressions.

Function
ABS
Call Format
ABS (X)
Version
All

Returns absolute value of expression $X . \quad A B S(X)=X$ if $X>=\varnothing, \quad-X$ if $\mathrm{X}<0$.

ASC ASC (XS) 8K, Extended, Disk
Returns the ASCII code of the first character of the string XS. ASCII codes are in appendix A.

ATN ATN (X) 8K, Extendea, Disk
Returns arctangent(X). Result is in radians in range -pi/2 to pi/2.

The following functions are available in Extended and Disk:
CINT CINT(X) Converts $X$ to integer.
CSNG $\operatorname{CSNG}(X)$ Converts $X$ to single precision.
CDBL CDBL(X) Converts $X$ to double precision.
If the argument is in the range -32768 to 32767 , the CINT (X) $=$ INT (X). Otherwise, CINT will produce an OVERFLOW error.

CHRS CHRS (I) . 8K, Extended, Disk
Returns a string whose one element has ASCII code I. ASCII codes are in Appendix A.
$\cos \operatorname{Cos}(X) \quad 8 \mathrm{~K}$, Extended, Disk
Returns $\cos (X) . X$ is in radians.
ERL Extended, Disk
Returns the number of the line in which the last error occurred.

ERR
Extended, Disk
Returns the error code of the last error.
ERR ERR(I) Disk
Returns parameters of disk errors. After a DISK I/O ERROR, ERR(0) returns number of the disk, ERR(1) returns the track number ( $0-76$ ) , ERR(2) returns the sector number, ERR(3) and ERR(4) return the low and high order 8 bits of the cumulative count of disk errors respectively.

EXP EXP (X) 8K, Extenāed, Disk
Returns e to the power $X . X$ must be $<=87.3365$.

Returns the truncated integer part of $X$. FIX(X) is equivalent to $\operatorname{SGN}(X) \times \operatorname{INT}(A B S(X))$. The major difference between $F I X$ and INT is that $F I X$ does not return the next lower number for negative $X$.

FRE $\operatorname{FRE}(\theta) \quad 8 \mathrm{~K}$, Extended, Disk
Returns number of bytes in memory not being used by BASIC. If argument is a string, returns number of free bytes in string space.

HEXS HEXS (X) Extended, Disk
Returns a string which represents the hexadecimal of the decimal argument.
INP
INP (I)
8K, Extended, Disk

Reads a byte from port $I$.
INSTR INSTR([I,]XS,Y\$). Extended, Disk
Searches for the first occurrence of string $y \$$ in $X S$ and returns the position. Optional offset I sets position for starting the search. $0<=I<=255$. III $I>L E N(X \$)$, if $X \$$ is null or if $Y \$$ cannot be found, INSTR returns $\varnothing$. If $¥ \$$ is null, INSTR returns I or l. Strings may be string variable values, string expressions or string literals.
INT
INT (X)
All

Returns the largest integer <=X
LEFTS LEFTS (XS,I) 8K, Extended, Disk
Returns leftmost $I$ characters of string $X \$$.
LEN
LEN (X\$)
8K, Extended, Disk
Returns length of string $x \$$. Non-printing characters and blanks are counted.

LOG LOG (X) 8K, Extended, Disk
Returns natural $\log$ of $x . \quad x>0$
LPOS LPOS (X) Extended, Disk
Returns the current position of the line printer print head within the line printer buffer. Does not necessarily give the
physical position of the print head. The expression $x$ must be given, but the value is ignored.

MID\$ MID\$(X\$,I[,J]) 8K, Extended, Disk
Without J, returns rightmost characters from $\mathrm{X} \$$ beginning with the Ith character. If I>LEN(XS), MIDS returns the null string. $\emptyset<I<255$. With 3 arguments, returns a string of length $J$ of characters from $x$ beginning with the Ith character. If $J$ is greater than the number of characters in $x \$$ to the right of $I, M I D \$$ returns the rest of the string. ض<=Јく=255.

аст§ $\quad$ аст\$(X) 8K, Extended, Disk
Returns a string which represents the octal value of the decimal argument.

RND
RND (X)
All
Returns a random number between $\emptyset$ and $1 . \quad x<\emptyset$ starts $a$ new sequence of random numbers. $x>0$ gives the next random number in the sequence. $X=\emptyset$ gives the last number returned. In 8 K , Extended and Disk, sequences started with the same negative number will be the same.

POS POS(I) 8K, Extended, Disk
Returns present column position of terminal's print head. Leftmost position $=\varnothing$.

RIGHTS RIGHT\$(X\$,I) 8K, Extendeã, Di
Returns rightmost I characters of string $X \$$. If I=LEN(X\$), returns X\$.

SGN SGN (X) All
If $X>\emptyset$, returns l, if $X=\emptyset$ returns $\emptyset$, if $X<\emptyset$, returns -1 . For example, $O N S G(X)+2$ GOTO $100,200,300$ branches to 100 if $X$ is negative, 200 if X is 0 and 300 if X is positive.

SIN SIN(X) All
Returns the sine of the value of $X$ in radians. $\operatorname{COS}(\mathrm{X})=\operatorname{SIN}(\mathrm{X}+3.14159 / 2)$.

SPACES SPACE\$(I) Extended, Disk
Returns a string of spaces of length $I$.

Returns string representation of value of $X$.
STRING\$ STRING\$ (I,J) Extended, Disk
Returns a string of length I whose characters all have ASCII code J. . See Appendix A for ASCII codes.

TAB
TAB (I)
All
Spaces to position I on the terminal. Space 0 is the leftmost space, 71 the rightmost. If the carriage is already beyond space $I$, TAB has no effect. $\emptyset<=I<=255$. May only be used in PRINT and LPRIŃT statements.

TAN TAN $(X)$ All
Returns tangent $(X)$. $X$ is in radians.
USR
USR (X)
All
Calls the user's machine language subroutine with argument $X$. VAL VAL (X\$) 8K, Extended, Disk

Returns numerical value of string $X \$$. If first character of $X \$$ is not + , - , or a digit, $\operatorname{VAL}(X \$)=0$.

VARPTR VARPTR(V) Extended, Disk

Returns the address of the variable given as the argument. If the variable has not been assigned a value during the execution of the program, an ILLEGAL FUNCTION CALL error will occur. The main use of the VARPTR function is to obtain the address of variable or array so it may be passed to an assembly language subroutine. Arrays are usually passed by specifying VARPTR(A[0]) so that the lowest addressed element of the array is returned.

NOTE
All simple variables should be assigned values in a program before calling VARPTR for any array. Otherwise, allocation of a new simple variable will cause the addresses of all arrays to change.

## 6-4. Special Characters

Altair BASIC recognizes several characters in the ASCII font as having special functions in carriage control, editing and program interruption. Characters such as control/C, Control/S, etc. are typed by holding down the Control key and typing the designated letter. The special characters in the table are listed in the order of the versions to which they apply, starting with those common to all versions and ending with those that apply only to extended versions.

Typed as:
Printed as:
The following Special Characters are available in ALL versions.
@
@
Erases current line and executes carriage return.

Erases last character typed. If there is no last character types a carriage return.

```
_(underline)
```

same as backarrow.
Carriage Return
Returns print head or curser to beginning of the next line.
Control/C AC (in Extended anā Disk)
Interrupts execution of current program or list command. Takes effect after execution of the current statement or after listing the current line. BASIC goes to command level and types OK. CONT command resumes execution. See section 6-1.

The following special characters are available in 8 K , Exteñed and Disk versions only.

Control/0 NO (in Extended and Disk)
Suppresses all output until an INPUT statement is encountered, another Control/o is typea, an error occurs or BASIC returns to command level.
?
?

Equivalent to PRINT statement.
Rubout see explanation
Deletes previous character on an input line. First Rubout prints $\backslash$ and the last character to be printed. Each successive Rubout prints the next character to the left. Typing a new character causes another $\backslash$ and the new character to be printed. All characters between the backslashes are deleted.

Control/U NU (in extended)
Same as @.
Control/s
Causes program execution to pause until Control/Q or Control/C is typed.

Control/Q
Causes execution to resume after Control/s. Control/s and Control/Q have no effect if no program is being executed.

The following special characters are available in Extended and Disk versions only.

Control/A
Allows use of the EDIT command on the line currently being typed. Control/A is typed instead of Carriage Return. See section 5-4.

Control/I 1 to 8 spaces
Tab character. Causes print head or curser to move to the beginning of the next 8 column field. Fielas begin at columns

1, 9, 17, etc. The tab character is especially useful for formatting lines broken with line feeds.

100<tab>FOR I=1 TO 10:<line feed>
<tab><tab>FOR J=1 TO 10:<line feed>
$\langle t a b\rangle\langle t a b\rangle\langle t a b\rangle A(I, J)=0:\langle l i n e$ feed〉
<tab>NEXT J,I<carriage return>

## lists as:

| 100 | FOR : $=1$ I TO 10: |
| :---: | :---: |
|  |  |
|  |  |
|  | NEXT J,I |
| col/G | bell |

Control/G bell
Rings terminal's bell.
LINE FEED
Breaks a long iline into shorter parts. The result is still one BASIC line.

Denotes the number of the current line. May be used wherever a line number is to be specified.

Brackets are interchangeable with parentheses as delimiters for array subscripts.

Lower Case Input
Lower case alphabetic characters are always echoed as lower case, but LIST, LLIST, PRINT and LPRINT will translate lower case to upper case if the lower case characters are not part of string literals, REM statements or remarks delineated by single quotation marks (').

6-5. Error Messages.

After an error occurs, BASIC returns to command level and types OK. Variable values and the program text remain intact, but the program cannot be continued by the CONT command. In 4 K and 8 K versions, all GOSUB and FOR context is lost. The program may be continued by direct mode GOTO, however. When
an error occurs in a direct statement, no line number is printed. Format of error messages:
$\begin{array}{ll}\text { Direct Statement } & \text { ?XX ERROR } \\ \text { Indirect Statement } & \text { ?XX ERROR IN YYYYY }\end{array}$
where $X X$ is the error code and YYYYY is the line number where the error occurrea. The following are the possible error codes and their meanings:

ERROR CODE EXTENDED ERROR MESSAGE NUMBER

The following error codes apply in ALL versions.

BS
SUBSCRIPT OUT OF RANGE
9
An attempt was made to reference an array element which is outside the dimensions of the array. In the 8 K and larger versions, this error can occur if the wrong number of dimensions are used in an array reference. For example:
$\operatorname{LET} A(1,1,1)=2$
when $A$ has already been dimensioned by $\operatorname{DIM} A(10,10)$
DD REDIMENSIONED ARRAY 10
After an array was dimensioned, another dimension statement for the same array was encountered. This error often occurs if an array has been given the default dimension of $l 0$ and later in the program a DIM statement is found for the same array.

FC ILLEGAL FUNCTION CALL 5
The parameter passed to a math or string function was out of range. $F C$ errors can occur due to:

1. a negative array subscript (LET A(-1)=ø)
2. an unreasonably large array subscript (>32767)
3. LOG with negative or zero argument
4. SQR with negative argument
5. AnB with $A$ negative and $B$ not an integer
6. a call to USR before the address of a machine language subroutine has been entered.
7. calls to MIDS, LEFTS, RIGHT\$, INP, OUT, WAIT, PEEK, POKE, TAB, SPC, STRING\$, SPACES, INSTR or ON...GOTO with an improper argument.

ID ILLEGAL DIRECT 12
INPUT and DEF are illegal in the direct mode. In extended versions, however, INPUT is legal in direct.

NF NEXT WITHOUT FOR 1
The variable in a NEXT statement corresponds to no previously executed FOR statement.

OD OUT OF DATA.
4
A READ statement was executed but all of the DATA statements in the program have already been read. The program tried to read too much aata or insufficient data was included in the program.

OM OUT OF MEMORY 7
Program is too large, has too many variables, too many $F O R$ loops, to many GOSUBs or too complicated expressions. See Appendix C.

OV
OVERFLOW
6

The result of a calculation was too large to be represented in Altair BASIC's number format. If an underflow occurs, zero is given as the result and execution continues without any error message being printed.

SN SYNTAX ERROR
Missing parenthesis in an expression, illegal character in a line, incorrect punctuation, etc.

RG RETURN WITHOUT GOSUB 3
A RETURN statement was encountered before a previous GOSUB statement was executed.

UL UNDEFINED LINE 8
The line reference in a GOTO, GOSUB, IF...THEN...ELSE or DELETE was to a line which does not exist.

Can occur with integer division and MOD as well as floating point division. $\emptyset$ to a negative power also causes a DIVISION BY ZERO error.

The following error messages apply to 8K, Extended and Disk versions only

CN
CAN'T CONTINE
17
Attempt to continue a program when none exists, an error occurred or after a modification was made to the program.

LS STRING TOO LONG 15
An attempt was made to create a string more than 255 characters long.

OS
OUT OF STRING SPACE
14
String variables exceed amount of string space allocated for them. Use the CLEAR command to allocate more string space or use smaller strings or fewer string variables.

ST STRING FORMULA TOO COMPLEX 16
A string expression was too long or too complex. Break it into two or more shorter ones.

TM TYPE MISMATCH 13
The left hand side of an assignment statement was a numeric variable and the right hand side was a string, or vice-versa; or a function which expected a string argument was given a numeric one or vice-versa.

UF UNDEFINED USER FUNCTION 18
Reference was made to a user defined function which had never been definea.

The following error messages are available in Extended and Disk versions only.

During evaluation of an expression, an operator was found with
no operand following it．

NO RESUME
19
BASIC entered an error trapping routine，but the program ended before a RESUME statement was encountered．

RESUME WITHOUT ERROR 21
A RESUME statement was encountered，but no error trapping routine had been entered．

UNPRINTABLE ERROR
22
An error condition exists for which there is no error message available．Probably there is an ERROR statement with an undefined error．code．

LINE BUFFER OVERFLOW
23
An attempt was made to input a program or data line which has too many characters to be held in the line buffer．Shorten the line or divide it into two or more parts．

ーーーー
Disk Altair BASIC Error Messages
－－－－

FIELD OVERFLOW
An attempt was made to allocate more than 128 characters of string variables in a single FIELD statement．

INTERNAL ERROR
51
Internal error in Disk BASIC．Report conditions under which error occurred and all relevant data to MITS software department．This error can also be caused by certain kinds of disk I／O errors．

BAD FILE
An attempt was made to use a file number which specifies a file that is not OPEN or that is greater than the number of files entered during the Disk Altair BASIC initialization dialog．

FILE NOT FOUND

Reference was made in a LOAD, KILL or OPEN statement to a file which did not exist on the disk specified.

BAD FILE MODE
An attempt was made to pebform a PRINT to a random file, to OPEN a random file for sequential output, to perform a pUT or GET on a sequential file, to load a random file or to execute an OPEN statement where the file mode is not $I$, $O$, or $R$.

EILE ALREADY OPEN 55
A sequential output mode OPEN for a file was issued for a file that was already OPEN and had never been CLOSEd or a KILL statement was given for an OPEN file.

DISK NOT MOUNTED
An I/O operation was issued for a file that was not MOUNTed.
DISK I/O ERROR
An $I / O$ error occured on disk X. A sector read (checksum) error occurred eighteen (18) consecutive times.

SET TO NON-DISK STRING
58
An LSET or RSET was given for a string variable which had not previously been mentioned in a FIELD statement.

DISK ALREADY MOUNTED
A MOUNT was issued for a DISK that was already MOUNTed but never UNLOADed.

DISK FULL
All aisk storage is exhausted on the disk. Delete some old disk files and try again.

INPUT PAST END
An INPUT statement was executed after all the data in afile had been INPUT. This will happen immediately if an INPUT is executed for a null (empty) file. Use of the EOF function to detect End Of File will avoid this error.

In a PUT or GET statement, the record number is either greater than the allowable maximum (2046) or equal to zero.

BAD FILE NAME
A file name of $\emptyset$ characters (null) or a file name whose first byte was 0 or 377 octal ( 255 decimal) or a file name with more than 8 characters was used as an argument to LOAD, SAVE, KILL or OPEN.

MODE-MISMATCH
Sequential OPEN for output was executed for a file that already existed on the disk as a random (R) mode file, or vice versa.

DIRECT STATEMENT IN FILE
65
A direct statement was encountered during a LOAD of a program in ASCII format. The LOAD is terminated.

TOO MANY FILES
66
A SAVE or OPEN (O or $R$ ) was executed which would create a new file on the disk, but all 255 directory entries were already full. Delete some files and try again.

OUT OF RANDOM BLACKS 67

An attempt was made to have more random files OPEN at once than the number of random blocks that were allocated during initialization by the response to the "NUMBER OF RANDOM EILES?" question (see Appendix H).

FILE ALREADY EXISTS
68
The new file name specified in a NAME statement had the same name as another file that already existed on the disk. Try a different name.

FILE LINK ERROR
69
During the reading of a file, a sector was read which did not belong to the tile.

6-6. Reserved Wordis.
Some words are reserved by the Altair BASIC interpreter for use as statements, commands, operators, etc. and thus may not be used for variable or function names. The reserved words are listed below in order of the versions for which they are reserved, starting with those reserved in all versions and ending with those reserved only in Disk Altair BASIC. Words reserved in larger versions may be used in smaller versions, although one may want to avoid all reserved words in the interest of compatibility. In addition to the words listed below, intrinsic function names are reserved words in all versions in which they are available.

RESERVED WORDS
Words reserved in all versions.

| CLEAR | NEW |
| :--- | :--- |
| DATA | NEXT |
| DIM | PRINT |
| END | READ |
| FOR | REM |
| GOSUB | RETURN |
| GOTC | RUN |
| IF | STOF |
| INPUT | TO |
| LET | TAB |
| LIST | THEN |
|  | USR |

words reserved in 8 K , Extended and Disk versions. All the above plus:

| AND | ON |
| :--- | :--- |
| CONT | OR |
| DEF | OUT |
| FN | POKE |
| NOT | SFC |
| NULL | WAIT |

Words reserved in Extended and Disk versions. All the above plus:

| AUTO | LINE |

Using ASCII codes -- the CHR\$ function.
CHRS(X) returns a string whose one character is that with ASCII code $X$. ASC(X\$) converts the first character of a string to its ASCII decimal value.

One of the most common uses of CHRS is to send a special character to the user's terminal. The most often used of these characters is the BEL (ASCII 7). Printing this character will cause a bell to ring on some terminals and a beep on many CRT's. This may be used as a preface to an error message, as a novelty, or just to wake up the user if he has fallen asleep. Example:

## PRINT CHR\$(7);

Another major use of CHRS is on those CRT's that have cursor positioning and other special functions (such as turning on a hard copy printer). For example, on most CRT's a form feed (CHRS(12)) will cause the screen to erase and the cursor to "home" or move to the upper left corner.

Some CRT's give the user the capability of drawing graphs and curves in a special point-ploter mode. This feature may easily be taken advantage of through use of Altair BASIC's CHRS function.
A. Loading BASIC from paper tape or cassette.

This appendix details the procedure for loading BASIC in $4 \mathrm{~K}, 8 \mathrm{~K}$ and Extended versions from paper tape or tape cassette. For instructions on loading Disk BASIC, see appendix $H$.

The programs below are entered into memory through the front panel switches. Rather than specify the switch positions as "up" and "down"; it is convenient to denote the up position as 1 and the down position as 0 . Taken in aroups of three the switches can represent octal digits. To save space, the switch positions in the following loader program listings are shown in octal notation. .. The leftmost two switches in an 8 bit set are represented by the first digit, the next three by the sacond digit and the low-order three switches by the last digit.

For example, if we wish to enter octal 315 on the data switch register, the switches would have the following positions:

| 7 | 5 | 5 | 4 | 3 | 2 | 1 | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| up |  | up | down | down | up | up | down |
|  |  |  |  | 1 |  |  | 5 |

For data entry, only the rightmost 8 switches of the 16 switches on the ALTAIR 88øg front panel switch register are used. All l6 switches would be used to enter a memory address.

The following is the procedure for loading BASIC from paper tape or cassette:

1. Turn the power switch on
2. Raise the STOP switch and RESET switch simultaneously
3. Switch the terminal to LINE
4. Enter one of the following programs on the front panel switches. The 88-MBL Multi-Boot Loader PROM contains the necessary loader programs, so it is not necessary to enter a loader from the front panel if it is installed. Refer to the $88-\mathrm{MBL}$ manual for more information.

To enter these programs:

1. Put switches 0 to 15 in the down oositions
2. Raise EXAMINE
3. Put the data for address zero in switches g through 7
4. Raise DEPOSIT
5. Put the data for the next address in the switches
6. Depress DEPOSIT NEXT
7. Repeat steos 5 and 6 until the whole loader is toggled in
8. Put switches 9 through 15 in the down position
9. Raise EXAMINE
10. Check to see that the lights D $\quad$ through D7 show the data that should be in location 000. Light on $=1$, light off $=$ 0 . If the correct value is there, go to step 13; if not, go to 11.
11. Put the correct value in the switches
12. Raise DEPOSIT
13. Depress EXAMINE NEXT
14. Repeat steps 10 through 13 to check the entire loader
15. If there were any mistakes, check the entire loader again to make sure they were corrected.
16. If a paper tape is being loaded, put it into the reader and make sure that it is positioned at the beginning of the leader. The leader is the section of tape at the beginning with 302 octal ounched in each column. If an audio cassette is being loaded, put it in the cassette recorder and make sure it is fully rewound.
17. Lower switches 0 through 15
18. Raise EXAMINE
19. Enter the sense switch settings. See the table in section $B$.
20. If loading is through a SIOA, $B$ or $C$ or an $88 p I O$, turn on the tape reader and then depress RUN. If a cassette is being loaded, turn on the recorder, put it in PrAy mode and wait 15 seconds. Then press RUN on the computer. If loading is through a 4 PIO , 2 SIO or High Speed Tape Reader, depress RUN and then start the read device.
21. Wait for the tape to read. Paper tape takes about 25 minutes for extended, 12 minutes for 8 K and 6 minutes for 4K. Cassettes take about 8 minutes for Extended, 4 minutes for 8 K and 2 minutes for 4 K . Do not move any of the switches while the tape is being read.
22. 

If a loading error occurs, the loading procedure must start over from steo 1 . See section $C$ below for error conditions.
23. When the tape is read, BASIC should start up and print MEMORY SIZE? See section $D$ below for what to do next.
24. If BASIC will not load from cassette, the ACR module may need realignment. The Input Test Program described in the ACR Manual, pages 22 and 28 , may be used to test the ACR.

## B. Sense Switch Settings

Sense switches (switches A8 through Al5) must be set before tape or cassette loading begins. The settings depend on the terminal and input interface boards in use. The low order (rightmost) four switches contain the load board setting, and the high order four switches contain the terminal board setting. In the table below, the setting is given for each I/O board option. As above, the setting is an octal number which signifies the switch positions. The Terminal Switch and Load Switch columns show the switches that are raised for each of the load and terminal device ootions.

Examples:
Input from audio cassette through $A C R$ and CRT terminal through 2 SIO with 1 stop bit. Switch $15 \quad 14 \quad 13 \quad 12 \quad 11 \quad 10 \quad 9 \quad 8$ Position $0 \quad 0 \quad 0 \quad 1 \quad 0 \quad 0 \quad 1 \quad 1$

Input from high speed paper tape reader, terminal through SIO.
$\begin{array}{lllllllll}\text { Switch } & 15 & 14 & 13 & 12 & 11 & 10 & 9 & 8\end{array}$ Position $\emptyset \quad \emptyset \quad 1 \quad 0 \quad \emptyset \quad 1 \quad 1 \quad \emptyset$
C. Error Detection

The checksum loader turns on the Interrupt Enable liaht on the front panel when a loading error occurs. The ASCII code of the error letter is stored in location 0. In addition, the error letter is sent out over all the terminal channels and appears on whatever terminal is connected to the terminal. The error letters are as follows:
C checksum error. Bad tape data.
M memory error. Data won't store properly.
The address of the bad memory location is stored
in locations l and 2 .
O overlay error. Attempt was made to load data on top
of the loader.
I invalid load device. Invalid setting on the
sense switches.
D. Initialization Dialog

Upon starting, BASIC prints
MEMORY SIZE?
To this, the user responds by typing the number of bytes of memory to be used by BASIC and BASIC orograms. Remember that the BASIC interpreter itself takes 3.4 K in the 4 K version, 6.2 K in 8 K and 14.6 K in Extended. If the response is just a carriage return, BASIC will use all the memory it can find, starting at location $z \in r o$ up to the last byte of read/write memory. Then BASIC asks,

TERMINAL WIDTH?
to which the user resoonds with the width of the printing line of whatever output device is in use. Tyoing a carriage return sets the terminal width to 72. Extended and Disk Altair BASIC set the terminal width throuqh the WIDTH command, so the TERMINAL WIDTH guestion is not asked at initialization and an initial width of 72 is assumed.

In 4 K , the response to MEMORY SIZE? and TERMINAL WIDTH? must be less than 6 digits.

The Extended and Disk versions now ask what kina of line printer is in use.

LINEPRINTER?
The user answers with $O$ if the $80 L P$ printer is in use, $C$ for
the $C 70 \emptyset$ and $Q$ for the 270 . One of these letters must be typed whether or not a lineprinter is connected to the system.

At this point .BASIC asks several questions about mathematical functions. The functions may be kept if needed or deleted to save space. 4 K asks,

SIN? Answer $Y$ to save $S I N, S Q R$ and RND Answer $N$ to delete $S I N$ and see the next question
SQR? Y keeps SQR and RND $N$ deletes $S Q R$, asks next question
RND? Y keeps RND N deletes RND

8 K and Extended BASIC ask,
WANT SIN-COS-TAN-ATN?
Y keeps all four N deletes all four A deletes only ATN $C$ (in extended) retains CONSOLE and all other functions. Other answers delete CONSOLE.

Now BASIC prints,
XXXX BYTES FREE
ALTAIR BASIC VERSION $4 . g$
[FOUR-K VERSION]
or
[EIGHT-K VERSION]
or
[EXTENDED VERSION]
COPYRIGHT 1977 BY MITS, INC. OK

BASIC is now in command level and is ready for use.
E. Echo Routines.

The Altair input/output channels work in a full-duplex mode. This means that characters entered on an input/output terminal will not, as a rule, be printed as they are entered unless the computer is programmed to return them. The following echo programs may be used to test the inout/output devices. To test an input-only device, dump the echoed characters on an output device or store them in memory for later examination. To test an output-only device, send the echo characters through the front panel switches or send a constant character. Be sure to check the ready-to-receive bit
of the output terminal before attempting output. If the echo program works, but BASIC does not, make sure the load device's I/O board is strapped for 8 data bits and that the ready-to-recieve bit is set properly on the terminal device.

SPACE $\frac{\text { APPENDIX }}{\text { AND SPEED }}$ HINTS
A. Space Allocation

The memory space required for a program depends, of course, on the number and kind of elements in the program. The following table contains information on the space required for the various program elements.

Element Space Required
Variables
numeric integer 5 bytes single precision 7 bytes in Extended and Disk 6 bytes in 4 K and 8 K double precision 11 bytes string 6 bytes

Arrays
integer (\# of elements)*[ $27+[6]+(\#$ of dimensions)*2 bytes single precision double precision string 8 K and 4 K strings and floating ot. $[5]+[5]$

Functions
intrinsic 1 byte for the call ( 2 bytes in Extended and Disk) user-defined 5 bytes for the definition

Reserved Words 1 byte each
2 bytes for ELSE in Extended and Disk
Other Characters
1 byte each

Stack Soace active FOR
loop 17 bytes in Extended and Disk,
16 bytes in 4 K and 3 K
active GOSUB 5 bytes
parentheses 6 bytes each set temporary
result 12 bytes in Extended and Disk 10 bytes in 4 K and 8 K

BASIC itself takes about 3.4 K in the 4 K version, 6.2 K in $8 \mathrm{~K}, 14.6 \mathrm{~K}$ in Extended and 20 K in Disk.
B. Space Hints

The space required to run a program may be significantly reduced without affecting execution by following a few of the following hints:

1. Use multiple statements per line. Each line has a 5 byte overhead for the line number, etc., so the fewer lines there are, the less storage is required.
2. Delete unnecessary spaces. Instead of writing
$1 \emptyset$ PRINT X, Y, Z
use
10 PRINTX,Y,Z
3. Delete REM statements to save 1 byte for REM and 1 byte for each character of the remark.
4. Use variables instead of constants, expecially when the same value is used several times. For example, using the constant 3.14159 ten times in a program uses 40 bytes more space than assigning

$$
10 \quad P=3.14159
$$

once and using $P$ ten times.
5. Using END as the last statement of a program is not necessary and takes one extra byte.
6. Reuse unneeded variables instead of defining new variables.
7. Use subroutines instead of writing the same code several times.
8. Use the smallest version of BASIC that will run the program.
9. Use the zero elements of arrays. Remember the array dimensioned by

100 DIM A(10)
has eleven elements, $A(0)$ through $A(10)$.
10. In Extended and Disk, use integer variables wherever possible.
C. Speed Hints

1. Deleting spaces and REM statements gives a small but significant decrease in execution time.
2. Variables are set up in a table in the order of their first appearance in the program. Later in the program, BASIC searches the table for the variable at each reference. Variables at the head of the table take less time to search for than those at the end. Therefore, reuse variable names and keep the list of variables as short as possible.
3. In 8 K , Extended and Disk use NEXT without the index variable.
4. 8 K , Extended and Disk have faster floating point arithmetic than 4 K . If space is not a limitation, use the larger versions.
5. The math functions in 8 K , Extended and Disk are faster than those in 4 K .
6. In the 4 K and 8 K versions, use variables instead of constants, especially in FOR loops and other code that must be executed repeatedly.
7. In Extended and Disk, use integer variables wherever possible.
8. String variables set up a descriptor which contains the length of the string and a pointer to the first memory location of the string. As strings are manipulated, string space fills up with intermediate results and wextraneous material as well as the desired string information. When this happens, BASIC's "garbage collection" routine clears out the unwanted material. The frequency of gargbage collection is inversely proportional to the amount of string space. The more string space there is, the longer it takes to fill with garbage. The time garbage collection takes is proportional to the square of the number of string variables. Therefore, to minimize garbage collection time, make string sọace as largge as possible and use as few string variables as possible.

## 1. Derived Functions.

The following functions, while not intrinsic to ALTAIR BASIC, can be calculated using the existing BASIC functions:

Function:
SECANT
COSECANT
COTANGENT
INVERSE SINE
INVERSE COSINE
INVERSE SECANT
INVERSE COSECANT
INVERSE COTANGENT
HYPEREOLIC SINE
HYPERBOLIC COSINE
HYPERBOLIC TANGENT
HYPERBOLIC SECANT HYPERBOLIC COSECANT HYPERBOLIC COTANGENT

INVERSE HYPERBOLIC SINE
INVERSE HYPERBOLIC Cosine
INVERSE HYPERBOLIC TANGENT
INVERSE HYPERBOLIC SECANT
INVERSE HYPERBOLIC COSECANT

INVERSE HYPERBOLIC
COTANGENT

BASIC equivalent:

```
SEC (X) = 1/COS (X)
```

$\operatorname{CSC}(X)=1 / \operatorname{SIN}(X)$
$\operatorname{COT}(X)=1 /$ TAN $(X)$
$\operatorname{ARCSIN}(X)=\operatorname{ATN}(X / S Q R(-X * X+1))$
$\operatorname{ARCCOS}(X)=-\operatorname{ATN} X(X / S Q R(-X * X+1))$
$+1.5708$
$\operatorname{ARCSEC}(X)=\operatorname{ATN}(X S Q R(X * X-1))$
$+\operatorname{SGN}(\operatorname{SGN}(X)-1) * 1.5708$
$\operatorname{ARCCSC}(X)=\operatorname{ATN}(1 / \operatorname{SQR}(X * X-1))$
$+(\operatorname{SGN}(X)-1) * 1.5708$
$\operatorname{ARCCOT}(X)=\operatorname{ATN}(X)+1.5798$
$\operatorname{SINH}(X)=(\operatorname{EXD}(X)-\operatorname{EXP}(-X)) / 2$
$\operatorname{Cosh}(X)=(\operatorname{EXP}(X)+\operatorname{EXP}(-X)) / 2$
TANH $(X)=\operatorname{EXP}(-K) / \operatorname{EXP}(X)+\operatorname{EXP}(-X))$
* $2+1$
$\operatorname{SECH}(X)=2 /(\operatorname{EXP}(X)+\operatorname{EXP}(=X))$
$\operatorname{CSCH}(X)=2 /(\operatorname{EXP}(X)-\operatorname{EXP}(-X))$
$\operatorname{COTH}(X)=\operatorname{EXP}(-X) /(\operatorname{EXP}(X)-\operatorname{EXP}(-X))$
* $2+1$

```
ARCSINH(X) = LOG (X+SQR(X*X+1))
ARCCOSH(X) = LOG (X+SQR(X*X+-1))
ARCTANH (X) = LOG ((1+X)/(1-X))/2
ARCSECH}(X)=\operatorname{LOG}((\operatorname{SQR}(-X*X+1)+1)/X
ARCCSCH(X) = LOG((SGN (X)*
    SQR (X*X+1)+1)/X
ARCCOTH (X) = LOG ((X+1)/(X-1))/2
```

2. Simulated Math Functions.

The following subroutines are intended for 4 K BASIC users who want to use the transcendental functions not built into 4 K BASIC. The corresponding routines for these functions in the

8K version are much faster and more accurate. The REM statements in these subroutines are given for documentation purposes only, and should not be typed in because they take up a large amount of memory. The following are the subroutine calls and their 8 K equivalents:

8K EQUIVALENT

```
P9=X9`Y9 GOSUB 60030
L9=LOG(X9) GOSUB 60090
E9=EXP(X9) GOSUB 60160
C9=COS(X9) GOSUB 60240
T9=TAN(X9) GOSUB 50289
A9=ATN(X9) GOSUB 60310
```

The unneeded subroutines should not be typed in. Please note which variables are used by each subroutine. Also note that TAN and COS require that the SIN function be retained when BASIC is loaded and initialized.

```

```

## APPENDIX E BASIC AND ASSEMBLY LANGUAGE

All versions of Altair BASIC have provisions for interfacing with assembly language routines. The USR function allows Altair BASIC programs to call assembly language subroutines in the same manner as BASIC functions.

The first step in setting up a machine lanquage subroutine for an Altair BASIC program is to set aside memory space. When BASIC asks, "MEMORY SIZE?" during initialization, the resoonse should be the size of memory available minus the amount needed for the assembly language routine. BASIC uses all the bytes it can find from location zero up, so only the topmost locations in memory can be used for user supplied routines. If the answer to the MEMORY SIZE? question is too. small, BASIC will ask the question again until it gets all the memory it needs. See Appendix C for Altair BASIC's memory requirements.

The assembly language routine may be loaded into memory from the front panel switches or from a BASIC program by means of the PORE statement.

The starting address of the assembly language routine goes in USRLOC, a two byte location in memory which varies from version to version. USRLOC for $4 K$ and $8 K$ Altair BASIC version 4.0 is 111 octal. In Extended and Disk, USRLOC need not be known explicitly since it is defined automatically by DEFUSR (section 5-3b). The function USR calls the routine whose address is in USRLOC. Initially, USRLOC contains the address of ILLFUN, the routine which gives the FC or ILLEGAL FUNCTION CALL error. If USR is called without an address loaded in USRLOC, an ILLEGAL FUNCTION CALL error results.

When USR is called, the stack oointer is set up for 8 levels (l6 bytes) of stack storage. If more stack space is needed, BASIC's stack can be saved and a new stack set up for use by the assembly language routine. BASIC's stack must be restored, however, before returning from the user routine.

All memory and all the registers can be changed by a user's assembly language routine. Of course, memory locations within BASIC ought not to be changed, nor should more bytes be popped off the stack than were put on it.

USR is called with a single argument. The assembly language routine can retrieve this argument by calling the routine whose address is in locations 4 and 5 decimal. The low-order byte of the address is in 4 and the high-order in 5 . In 4 K and 8 K , this routine (DEINT) stores the argument in the register pair [D,E]. In Extended and Disk, the arqument is
passed in pair [H,L]. The argument is truncated to integer in 4 K and 8 K , and if it is not in the range -32758 to 32767 , an FC error occurs. In Extended and Disk, the register pair [H,L] contains a pointer to the Floating point Accumulator where the argument is stored (see section 5-3b. for more information about use of the Floating point Accumulator).

To pass a result back from an assembly language routine, load the value in register pair $[A, B]$ in $4 K$ and $8 K$, or $[H, L$ ] in Extended. This value must be a signed, 16 bit integer as defined above. Then call the routine whose address is in locations 5 and 7. If this routine is not called, USR(X) returns $X$. To return to BASIC, then, the assembly language routine executes a RET instruction.

Assembly language routines can be written to handle interrupts. Locations 56,57 and 58 are used to hold a JMP instruction to a user supplied interrupt handing routine. Location 56 initially holds a RET, so it must be set up by the user or an interrupt will have no effect.

All interrupt handing routines should save the stack, registers $A-L$ and the PSW. They should also reenable interrupts before returning since an interrupt automatically disables all further interrupts once it is received.

There is only one way to call an assembly language routine in 4 K and 8 K , but this does not limit the programmer to only one assembly language routine. The arqument of USR can be used to designate which routine is being called. In 8K, additional arguments can be passed through the use of pOKE and values may be passed back by PEEK.

In Extended and Disk BASIC, up to ten routines may be called with the USRD - USR9 functions. For more information on this feature, see section 5-3b.

APPENDIX F
USING THE ACR INTERFACE

NOTE
The cassette features , CLOAD and CSAVE, are only present in 8 K Altair BASICs which are distributed on cassette and in Extended and Disk versions. 8K BASIC on paper tape will give the user about 250 additional bytes of free memory, but it will not recognize the CLOAD or CSAVE commands.

Programs may be saved on cassette tane by means of the CSAVE command. CSAVE may be used in either direct or indirect mode, and its format is as follows:

CSAVE <string expression>
The program currently in memory is saved on cassette under the name specified by the first character of the <string expression>. CSAVE writes through channel 7 when the Nrite Buffer Empty bit (bit 7) of channel 6 is low. After CSAVE is completed, BASIC always returns to command level. Programs are written on tape in BASIC's internal representation. Variable values are not saved on tape, although an indirect mode CSAVE does not affect the variable values of the program currently in memory. The number of nulls (see NULL command) has no affect on the operation of CSAVE. Before using CSAVE, turn on the cassette recorder. Make sure the tape is in the proper position then put the recorder in RECORD mode.

Programs may be loaded from cassette tape by means of the CLOAD command, which has the same format as CSAVE. The effect of CLOAD is to execute a NEW command, clearing memory and all variable values and loading the specified file into memory. When done reading and loading, BASIC returns to command level. CLOAD reads a byte from channel 7 when the Read Data Ready bit (bit 0 ) in channel 6 is low. Reading continues until 3 consecutive zeros are read. BASIC will not return to command level after a CLOAD if it could not find the requested file, or if the file was found but did not end with 3 zeros. In that case, the computer will continue to search until it is stopped and restarted at location 0 .

In the 8 K cassette and Extended versions of ALTAIR BASIC, data may be read and written with the CSAVE* and CLCAD* commands. The formats are as follows:

CSAVE*<array variable name>
ana
CLOAD*<array variable name>
See section 2-4d for a discussion of CSAVE* and CLOAD* for array data.

CLOAD?<string expression> compares the program currently in memory with the specified file on cassette. If the two files match, BASIC prints OK. If not, BASIC orints NO GOOD.

Data may also be read from and written on cassette in the paper tape version of 8 K Altair BASIC. To write data, execute a WAIT 6,128 statement to check for the Write Buffer Empty bit and then write with an OUT 7 , <byte> statement. To read, execute a WAIT 6,1 to check for Read Data Ready and then read with an INP(7). The end of a block of data may be conveniently designated by a special character. Data should be stored in array form since there is no time during reading and writing for computation.

APPENDIX G
CONVERTING BASIC PROGRAMS
NOT WRITTEN FOR THE ALTAIR COMPUTER

Though implementations of BASIC on different computers are in many ways similar, there are some incompatibilities between ALTAIR BASIC and the BASIC used on other computers.

## 1) Strings.

A number of BASICs require the length of strings to be declared before they are used. All dimension statements of this type should be removed from the program. In some of these BASICs, a declaration of the form DIM AS (I,J) declares a string array of $J$ elements each of which has a length I. Convert DIM statements of this type to equivalent ones in Altair BASIC: DIM A\$(J). Altair BASIC uses " + " for string concatenation, not " , " or " \& ." ALTAIR BASIC uses LEFT\$, RIGHTS and MID\$ to take substrings of strings. Some other BASICs use AS (I) to access the Ith character of the string AS, and $A \$(I, J)$ to take a substring of $A \$$ from character oosition I to character position J. Convert as follows:

OLD
AS (I)
$A \$(I, J)$

NEW
MIDS (AS,I,I)
MIDS(A\$,I,J-I+1)

This assumes that the reference to a subscript of $A \$$ is in an expression or is on the right side of an assignment. If the reference to $A \$$ is on the left hand side of an assignment, and $X \$$ is the string expression used to replace characters in $A S$, convert as follows:

In $4 K$ and $8 k$
OLD
$A \$(I)=x \$$
NEW
$A \$(I, J)=X \$$
$A S=\operatorname{LEFTS}(A \$, I-1)+X S+M I D S(A S, I+1)$
$A S=\operatorname{LEFTS}(A S, I-I)+X S+M I D \$(A S, J+1)$
Extended and Disk
OLD
NEW
A $(I)=X \$$
MIDS (AS, 1, 1) =X
$A S(I, J)=X \$$
$\operatorname{MID} \$(A \$, I, J-I+1)=X \$$
2) Multiple assignments.

Some BASICs allow statements of the form:
500 LET $B=C=0$

This statement would set the variables $B$ and $C$ to zero. In $8 k$ Altair BASIC, this has an entirely different effect. All the $"="$ signs to the right of the first one would be interoreted as logical comparison operators. This would set the variable $B$ to -l if $C$ equaled 0 . If $C$ did not equal $0, B$ would be set to 0 . The easiest way to convert statements like this one is to rewrite them as follows.

500 $\mathrm{C}=0: \mathrm{B}=\mathrm{C}$
3) Some BASICs use " \" instead of " : " to delimit multiole statements on a line. Change each " " to " : " in the program.
4) Paper tapes punched by other BASICs may have no nulls at the end of each line instead of the three per line recommended for use with Altair BASIC. To get around this, try to use the tape feed control on the Teletvpe to stop the tape from reading as soon as Altair BASIC prints a carriage return at the end of the line. Wait a moment, and then continue feeding in the tape. When reading has finished, be sure to punch a new tape in Altair BASIC's format.

A program for converting tapes to Altair BASIC's format was published in MITS Computer Notes, November 1976, D. 25.
5) Programs which use the MAT functions available in some BASICs will have to be rewritten using FOR...NEXT loops to perform the appropriate operations.

> APPENDIX

DISK INFORMATION

Format of Altair Eloppy Disk

Track Allocation:
Tracks Use
0-5 Disk BASIC memory image.
6-69 Space for either random or sequential files.
70 Directory track. See below.
71-76 Space for sequential files only.
Format of DISK BASIC Memory Image (Tracks 0-5):

BASIC is loaded starting at track $\emptyset$ sector $\varnothing$ then track $\emptyset$ sector 1 , etc. Each sector contains 128 bytes of BASIC. The first 128 bytes are loaded first, second 128 second, etc.

Sector format (Tracks $0-5$ ):
Byte Use
0 Track Number+128 decimal.
1-2 Sixteen bit address of the next higher byte of memory than the highest memory location saved on this sector.
3-130 128 bytes of BASIC.
131255 decimal stop byte.
132 Checksum - sum of bytes $3-130$ with no carry in 8 bits.

Sector format (Tracks 6-76) :
Byte Use
$0 \quad$ Most Significant Bit always on. Contains track number plus 200 octal.
1 Sector number * 17 MOD 32.
2 File number in directory. Zero file number means that the sector is not part of any file. If the sector is the first file of a group of 8 sectors 0 means the whole group of 8 sectors is free.
3 Number of data bytes written ( 0 to 128) . Always 128 for random files. (Except for the random file index blocks in which case this byte indicates how many
groups are allocated to the file.)
Checksum. The sum of all the data on the sector except for the track number, the sector number and the terminating 255 byte.
5,6 Pointer to the next group of data. This is set up for random files and sequential files, and is even valid in the middle of a group. If it is zero it means there is no more data in the file. The track is the first byte and the sector number is the second byte.
7-134 Data
135 A 255 (octal 377) to make sure the right number of data bytes were read.
136 Unused.
Directory Track (70) Format:
Each sector of the directory (which is all of track 70) is composed of up to 8 file name slots, 16 bytes per slot. Each slot can contain a file name ( 8 bytes), a link to the start of file data ( 2 bytes) and a byte which specifies the mode of a file (Random=4, Sequential=2). The remaining 5 bytes are not currently used. Any slot which has the first file name byte equal to zero contains a file which has been deleted. If the first byte of a slot is a 255 , it is the last slot currently in use in the directory. Slots beyond the "stopoer" are garbage. File numbers are calculated by multiplying the sector number of the directory track the file is in by 8 and adding the position of the slot in the sector ( $\varnothing-7$ ) plus 1.

## NOTE

The ith logical sector on a track is actually mapod to the i*I7 MOD 32 ohysical sector to shorten access time in BASIC I/O operations.

Format of Random Files

Each random file starts with two random index blocks. The "number of data bytes" field in the first block indicates how many groups are currently allocated to this random file. The next 256 bytes in the two random index blocks give the location of each group in the random file in order of their position in the file. The upper two bits give the group number , and the lower six bits give the track number - 6 .

Assembly Code to Read and Write a Sector

The following code has been provided to helo users write their own assembly language subroutines to read and write data on the floppy disk. It is assumed that the disk being used has already been enabled and positioned to the correct track. Two data bytes are always read or written at a time so that the CPU can keep up with the data rate ( 32 microseconds/byte) of the floppy disk. After two bytes are read or written, the CPU re-synchronizes with the next 'byte ready' status from the floppy disk controller.
; CALL WITH NUMBER OF DATA BYTES TO WRITE IN [A]
; AND POINTER TO DATA BUFFER IN [H,L]
; ALL REGS DESTROYED.

The Disk PROM Bootstrap Loader

The Disk Bootstrap Loader PROM must be installed in the highest position on the PROM board and the PROM board must be strapped at the proper address. The proper position is the PROM IC socket on the opposite side of the board from the black finned heat sink. The black dot or 'l' on the PROM should be in the upper left corner. The address jumpers on the PROM board must be in the 'l' position.

To use the Disk Bootstrap Loader, turn the computer's power on. Raise RESET and STOP simultaneously. Lower RESET and then STOP. EXAMINE location 177400 (address switches Al5-A8 up, rest down) and then set the sense switches for the terminal $I / O$ board as explained in Appendix B. Depress the RUN switch. BASIC should print (or display):

MEMORY SIZE?
For the rest of the initialization procedure, see below.

Using the Cassette and Paper Tape Bootstraps

If the Disk Bootstrap Loader PROM is not in use, a paper tape or cassette program must be loaded which then reads in BASIC from the disk. This is done by following the procedure below:

1. Key in the apolicable paper tape or cassette bootstrap loader from the listings in Aopendix B. Make location $2=077$ octal. Set the sense switches for the terminal.
2. Start the paper tape or cassette (labeled DISK LOADER) reading, and then start the computer as in the instructions for loading BASIC from paper tape from cassette as given in Appendix B.

BASIC should respond:
MEMORY SIZE?
For the rest of the initialization procedure, see below.

> Disk Initialization Dialog

The initialization dialog has been expanded to allow the user to select the proper amount of memory needed to use the disk(s) on the system. After the the MEMORY SIZE question is answered, BASIC will ask:

HIGHEST DISK NUMBER?
The user should answer with the highest physical disk address in the system or with a carriage return. The default is 0 . Each additional disk uses $4 \emptyset$ bytes of memory.

Example:

HIGHEST DISK NUMBER? I
BASIC next asks how many files are to be OPEN at one time in the program. This number includes both random and sequential files. If the user tyoes carriage return, the default is zero. Each file allocated requires 138 bytes for buffer space. Example:

HOW MANY FILES? 2
Finally, BASIC asks how many random files are to be OPEN at one time. The amount of memory allocated is the answer*257. This memory space is used to keep track of the location on the floppy disk where groups of a random file reside. Thus, the total memory reguired for each random file is $138+257=395$ bytes. Example:

HOW MANY RANDOM FILES? 1
A typical dialog might appear as follows:
MEMORY SIZE? <carriage return> HIGHEST DISK NUMBER? <carriage return>
HOW MANY FILES? 2 <carriage return>
HOW MANY RANDOM FILES? 1 <carriage return>
xXXXX BYTES FREE
ALTAIR BASIC REV. 4.0

## APPENDIX I <br> THE PIP UTILITY PROGRAM

A BASIC Utility program has been provided to perform such such common functions as printing directories, initializing disks, copying disks etc.

NOTE
Some of the PIP commands (LIS, DIR) require that one <file number> be configured during the Disk BASIC initialization dialog. This is done by answering the "HOW MANY FILES?" question with a value greater than zero. If an attempt is made to perform a LIS or DIR without following this procedure, a BAD FILE NUMBER error will occur.

Once the BASIC disk has been mounted, type the following command:

RUN "PIP"<carriage return>
(PIP will type)
*
PIP is now ready to accept commands. To exit PIP, type a carriage return to the prompt asterisk. To initialize the floppy disk in drive 0 , type:
*INID
PIP will type "DONE" when it is finished. Any disk number may be substituted for the $\emptyset$ in the above command and PIP will format the disk in that drive. Any orevious files on the disk initialized will be lost. If you wish to use blank disks with Disk BASIC, they must be initialized in this fashion before they can be MOUNTed.

NOTE
DO NOT INITIALIZE THE DISK WITH DISK EXTENDED BASIC ON IT. THIS WILL WIPE OUT ALL THE FILES PROVIDED ON THE DISK.

```
Printing a Directory
```

Giving PIP the command:
*DIR<disk number>
prints out a directory of the files on the specified disk. The name of each file is printed along with the file's "mode" ( $S$ for sequential, $R$ for random) and the starting track and sector number of the first block in the file.

SRT<disk number>
prints a sorted directory of the files on the specified disk.

## LISting Sequential Files

The LIS command is used to list the contents of a sequential data file on the terminal:

## Syntax:

LIS<disk number>, <file name>
Example:
*LISØ,PIPA user types
7 CLEAR loø0 computer prints
-
-
-
*

COPying Disks

The COP command is used to copy a disk placed in one drive to a disk on another drive. Neither disk need be MOUNTed for the COP command to work properly.

Syntax:
COP<old disk number>, <new disk number>

Before the copy is done, PIP verifies the action by printing the following massage:

FROM<disk number>TO<disk number>
Typing $Y$ followed by a carriage return causes execution to proceed. Any other response aborts the command. Example:
*COPの,1
FROM D TO 1? Y<carriage return> DONE
*

The DAT command

The DAT command is used to dump out a particular sector of the disk in octal.

Syntax:
DAT<disk number>
When the DAT command is issued, PIP asks for the numbers of the track and sector to be dumped. Example:
*DAT0
(DAT is equivalent)
TRACK? $\emptyset$
SECTOR? 0

The CNV command

CNV converts disks written under Altair BASIC version 3.4 and 3.3 to a format useable by version 4.0. The format of the command is as follows:

CNV<disk number>
CNV makes sure that the next to last byte of each sector is 255.

## APPENDIX J <br> RSTLESS VERSIONS OF BASIC

Altair BASIC uses the so-called RST locations (locations 0 through 100 octal) at the bottom of memory. This saves memory space, but precludes the use of the Vector Interrupt board for real-time programming apolications. Special versions of Altair BASIC are available which do not use the RST locations, however. These versions leave the RST locations free to be used for assembly language routines in the same was as any other locations in high memory.

To restart the standard versions of Altair BASIC, it is necessary simply to actuate the RESET switch on the computer's front panel. This causes a jump to location 0 . In the RSTLESS version, BASIC is restarted by jumping to location 100 octal. The usual procedure for doing this is as follows:

1. Raise STOP and RESET simultaneously, then release them
2. Raise switch A6
3. Actuate EXAMINE
4. Push RUN

BASIC restarts and prints "OK."

## APPENDIX K

USING Altair BASIC ON THE
INTELLEC* $\overline{3 / M O D}$ 8

This appendix covers procedures for loading and operating Altair BASIC on Intellec and MDS development systems.
A. Loading BASIC.

To load Altair BASIC, put the hex paper tape of BASIC in the system reader device. Enter the System and assign the CONSOLE I/O device as desired (see Section 4.2.1 of the Intellec 8/Mod 80 Operator's Manual). Now read in BASIC with the following $R$ command.
. R (Cr)

The BASIC tape will be loaded into memory, and the system monitor will type a period on the CONSOLE device. If you are only using contiguous RAM memory below the system monitor (3800H) or are using BASIC on a MDS System, proceed to step 2. If you have RAM memory above the PROM Intellec monitor which you wish BASIC to use for program and variable storage, you must patch the two locations known as INTLOC to point to the bottom (lowest address) of memory. The is most easily accomplished by using the System Monitor S command. INTLOC is given below under "Memory Requirements."
. SXXXX Øø 40 (Cr)
The above $S$ command would make INTLOC point to RAM, starting at 16 K .

NOTE
If you are using RAM above 16 K for orogram and variable storage and have patched INTLOC, retain all the math functions at initialization time (see Appendix B). Essentially, this means that the WANT SIN-COS-TAN-ATN? questions asked by BASIC's initialization dialog should be answered by a $Y(C r)$. Also, you must answer the MEMORY SIZE? question with the highest decimal or RAM address in your system.

Start BASIC by giving the monitor GOTO command.
-G0000<carriage return>

NOTE
Once BASIC has been started, it may always be restarted by depressing the RESET switch on the Intellec 8 console.

When BASIC types MEMORY SIZE?, typing carriage return will cause BASIC to use all the RAM memory it can find above the end of BASIC. Otherwise, if you wish to specify an exact amount of memory, type the decimal address of the highest byte of memory in the computer and type carriage return.
B. BASIC I/O.

The system devices used for terminal I/O in BASIC are CI, CO and CSTS.
C. Saving and Loading Programs.

To save a program on paper tape, re-enter the PROM monitor and reassign the CO device to the paper tape punch or other outout device. Then restart BASIC by using the Gø0ø0 command and type LIST(Cr). The characters of the LIST command will not be echoed, but the BASIC program currently saved in memory will be put on the output device.

To load a program, enter the system monitor, re-assiqn CI to the input device where the program resides, and then start BASIC with a GODDD. When the program has been completely read in, reassign CI to the user console. Then re-enter BASIC with a Gøøøø, and start the I/O device. The program will be echoed on CO as it is read in.
D. Memory Requirements

BASIC uses locations $0900 \mathrm{H}-0003 \mathrm{H}$ and $0010 \mathrm{H}-a p p r o x i m a t e l y$ 19DFH in the 8 K version, and $0010 \mathrm{H}-2 \mathrm{FDEH}$ in the Extended version. For Intellec 8 K and MDS 8 K BASICs, INTLOC is 6520 decimal. For MDS Extended, INTLOC is 14257 decimal.
E. Calling Assembly Language Routines

USRLOC for 8 K BASIC is $0655 \mathrm{H} . \mathrm{ADR}$ (DEINT) is stored in locations $0043 \mathrm{H} . \mathrm{ADR}(G I V A C F)$ is stored in location 9045 H . In the Extended version, these locations contain the addresses of

FRCINT and MAKINT, respectively. Interrupt driven subroutines using RST 7 are not allowed in the Intellec/MDS version of Altair BASIC. See Appendix $C$ for further information on calling assembly language subroutines. Corporation.

## APPENDIX L <br> PATCHING BASIC'S I/O ROUTINES

BASIC's I/O routines may be changed to accommodate non-standard terminal equipment. After BASIC is loaded and before it has been initialized, location 71 contains a pointer to a list of addresses. These addresses contain the $I / O$ routines of BASIC:

|  | ORG | 701 |  |
| :---: | :---: | :---: | :---: |
|  | DW | IOLST | ;TWO BYTE ADDRESS OF ADDRESS LIST |
|  | - |  |  |
|  | - |  |  |
| IOLST: | DW | TRYIN | ; CHARACTER INPUT ROUTINE |
|  | DW | TRYOUT | ; ADDRESS OF OUTPUT ROUTINE |
|  | DW | ISCNTC | ; POLL FOR CONTROL/C CHECK |
|  | DW | NENSTT | ;FAST POLL FOR CONTROL/C CHECK <br> ; 8 K AND LARGER ONLY |
|  | DW | IN2SIO | ; ADDRESS OF INITIALIZATION |
|  |  |  | ; ROUTINE FOR 2SIO BOARDS |
|  | DW | IN4PIO | ;ADDRESS OF INITIALIZATION ROUTINE FOR ; 4 PIO BOARDS |
|  | DW | LPTPOS | ;ADDRESS OF LPT CODE FLAGS |
|  | DW | LPT3CD | ; START OF LPT CODE |
|  | DW | ENDLPT | ; END OF LPT CODE |
|  | DW | IOCHNL | ;ADDRESS OF I/O RESET LOCATION <br> ;(IN EXTENDED AND DISK ONLY) |
|  | - |  |  |
|  | - |  |  |
| TRYOUT: | IN | 0 | ;GET DEVICE STATUS |
|  | ANI | 200 | ; AND OFF BIT 7 |
|  | JNZ | TRYOUT | ; WAIT UNTIL TERMINAL CAN OUTPUT |
|  | POP | PSW | ;GET CHARACTER TO OUTPUT OFF STACK |
|  | OUT | 1 | ; TRANSMIT IT |
|  | PUSH | PSW |  |
|  | NOP |  | ;CHANGED TO "IN 41" FOR $4 P I O$ BOARDS |
|  | NOP |  |  |
|  | POP | PSW | ;GET CHARACTER BACK OFF STACK |
|  | RET |  | ;ALL DONE WITH CHARACTER OUTPUT ROUTINE |
|  | - |  |  |
|  | - |  |  |
| TRYIN: | IN | 0 | ; GET TERMINAL StATUS |
|  | ANI | 1 | ;CHARACTER READY? |
|  | JN2 | TRYIN | ; NO, KEEP WAITING |
|  | IN | 1 | ; READ IN THE CHARACTER |
|  | ANI | 127 | ;GET RID OF PARITY BIT |

A comma in a LPRINT statement causes the printhead to move to the beginning of the next 14 column field. If LPTPOS is greater than NLPPOS, a carriage return line feed sequence is executed before printing. NLPPOS is calculated by the following relation:

$$
\text { NLPPOS }=\operatorname{INT}(((L P T L E N / 14)-1) * 14)
$$

LPTLST is used only by the 80LP printer. QPOS and QMOV are used only by the $Q 7 D$. The user should not modify the PRTFLG flag since it is modified and referred to in several places in BASIC. Changing it in a USR routine has unpredictable results.
B. Start of LPT code.

LPT3CD: JMP FINLPT
JMP PRINTW
-
.
body of LPT code
-
-
-
The main body of LPT code is entered whenever PRTFLG is determined to be non-zero. The character to be output must be at the top of the stack. Upon exit from LPT code, the character must be removed from the stack and should be loaded into the Accumulator. This is because BASIC checks the Accumulator for the last character orinted.

FINLPT is entered whenever BASIC returns to command level. FINLPT calls PRINTW for a carriage return/line feed sequence, if necessary, and resets PRTFLG to zero.

PRINTW does the carriage return/line feed.
FINLPT and PRINTW both return with zero loaded in the Accumulator and all the condition codes set to zero.
C. End of LPT code

ENDLPT is the ohysical end of the lineorinter driver code.

The following routines are used in with all terminal devices:

| IOCHNL: |  |  | ; DEPOSIT BOARD TYPE HERE |
| :---: | :---: | :---: | :---: |
|  |  |  | ; CHANNEL GETS DEPOSITED HERE. |
| IOREST: | LXI | H,IOCHNL | ;GRAB POINTER TO IT |
|  | CALL | HELPIO | ; SET UP THE NEW CONSOLE DEVICE |
|  | CALL | STKINI | ; MAKE STACK OK |
|  | JMP | READY | ;AND TYPE "OK" HOPEFULLY ON GOOD CONSOI |

To modify the $I / O$ routines, stop the machine after loading BASIC and insert the changes using the front panel switches, or read in a tape containing the patches. Restart BASIC at location zero with all sense switches up. This will prevent BASIC from modifying the $I / O$ routines. In general, these quidelines should be followed in writing I/O routines:

1. Insert a JMP at TRYOUT to the custom output routine. Be sure the PSW that is saved on the stack when the routine is entered is preserved. Make sure all registers are left unchanged when the routine is exited.
2. Insert a JMP at TRYIN to the custom input routine. Return the input character in the $A$ register and do not change any of the other registers. The PSW may be changed.
3. To modify ISCNTC, insert a CALL to the custom poll routine. This routine returns a non-zero condition code setting if no character is present and zero if a character is present. The A register and the condition codes may be changed.
4. To change the initialization of the 2 SIO board, change the "ADI 23Q" to "MVI A,XXX" where XXX is the new initialization byte.
5. To change the initialization of the $4 P I O$ board, change the "MVI A,54Q" to a "MVI A,XXX" where XXX is the new initialization byte.
6. To patch in a new line orinter driver, chanae the code at LPTCOD. Note that PRINTW is also called by the foutine which prints a carriage turn line feed. The code at LPTCD2 and LPTCD3 must be changed if the line printer is not 80 characters wide.
7. To recover from an incorrect CONSOLE command, deposit the board type in IOCHNL, the board type in IOCHNL+1, and start the machine at IOCHNL+2.

Patching Disk BASIC - the PTD program.
After Disk BASIC is loaded, deposit the desired patches in memory. Then examine and run PTD at location 540 gog octal. After two or three seconds, the patched version of BASIC will be saved on disk. The save is complete when the Disk Enable light on disk drive zero goes out.

To save a patched version of BASIC on a disk which did not previously contain release 4.0 Altair BASIC, track 0 must be copied from a 4.0 disk.

PTD may also be used to save programs other than BASIC on tracks 0-4 of a diskette by loading the program after BASIC is loaded and running PTD. All memory locations between 0 and $460 \emptyset 0$ octal will be saved on tracks 0-4 on diskette zero.

## APPENDIX M <br> USING ALTAIR DISर̄ BASIC <br> An Example

The following is a discussion of how to program a typical application in BASIC. The example is the MITS in-house inventory system which is designed to run on the following hardware:

Altair 8800b computer with 32 K memory, PROM memory board with the Disk PROM Bootstrap loader and a 2SIO serial I/O board
Two disk drives
24-line Lear-Sigler CRT terminal
Line printer
The most important part of the design for an application is setting up the files. Files that are correctly set up will be easy to use and maintain. Poorly set up files will be a perpetual headache, causing either an eventual rewrite or, more likely, abandonment of the system.

The first listing at the end of the appendix, INVEN, contains modules from the main program in the inventory system. INVEN shows how the central file (a random file) in the system is set up and how it is handled. The INVEN listing also shows the use of another random file and a sequential file. The CALC listing shows how to read programs as data files. CODEl is a partial listing of a proqram that will be read as a data file.

The INVEN modules listed were included to show the following features:

1. program startup initialization and comments about the files used by the program (lines l-35)
2. what the complete program does (Iines 60-10 $\quad$ (
3. an example of how to modify records in a random file (lines 900-1040)
4. an example of how sequential files are used (lines 1800-1868 and 2700-2820)
5. one approach to the problem of handling a random file that spans more than one disk (lines 2000-2030)
6. three subroutines (1ines $300-340,9000-9020$ and $9200-9220$ ) that are called by the INVEN modules.

The function FNY (line 6) is used to round dollar amounts to thousandths of a cent. FNQ (line 7) is used to round quantities to thousandths and to convert single precision amounts to double precision.

INV3 is fielded once in the program initialization, but INV1 and INV2 are repeatedly fielded by calls to the subroutine at line 2000 . The IF $5>255$ (line 60) avoids the possibility that the program can be stopped by an illegal function call at line 61 .

PUT statements are the very last statements executed in the Remove from Inventory module, the Add to Inventory module, etc. This prevents updating one file but not the other. (This could happen if PUT $Z, R 1$ was at line lglo.)

Line 2000 sets $Z$ to $l$ and $R 1$ to $N$ if the item wanted, $N$, is less than 2001. It sets 2 to 2 and Rl to $N-2000$ if the item wanted is greater than 2000 . Line 2020 then sets the pointers for the variables in the field statement to point into either the buffer for INV1 or the buffer for INV2, depending on whether the item wanted is less than 2001 or greater than 2000.

The CALC listing is a program which determines if there are enough parts in inventory to meet projected demands. Line 60 waits while the disk comes up to speed so the message "ENABLE DISK 1 " will not be printed on the terminal. Lines lob-140 input up to fifty different oroduct codes and the number of each product to be built. Line 179 opens a file for each product that contains the parts required for the product. Lines 220-250 build up a report heading, extracting the product description contained in line 10 of each file.

Lines 120-150 accumulate the number of parts required for each product into the array Q. If more than 32767 of a part is required, a pointer is set in the array $Q$ and the number of the part is accumulated in the array Q!. This maneuvering is necessary since the system does not have enough memory to dimension $Q$ as single precision instead of integer.

The parts lists for a product are programs saved with the A option. Since they are programs, their maintenance is very easy. For example, suppose that part l07l in the $8800 b$ is too marginal and that from now on part 1173 should be used instead. With the parts lists disk mounted on drive $\emptyset$, the following sequence will update the 8800b file:

```
LOAD "CODEl"
160,1,1173
SAVE "CODEl",9,A
```

The programmer who is cramped for memory will find that programs can still be documented adequately if comments are set up as separate files. The memory used for variables when a program runs can be used for comments if the comments are merged in when the program is to be listed. Alternatively, the program could be listed in two or more parts. Additional memory can be obtained by bringing BASIC up without optional functions and with no files.

The main inventory program is set up so that a carriage return typed in response to any prompt causes the program to dump the function descriptions on the CRT and to return to the FUNCTION NUMBER prompt. If the program were to be run on a printing terminal, instead of a 9600 baud CRT, it would not be set up to print the descriptions every time the operator wanted to get back to the FUNCTION NUMBER promot. The list of function descriptions might be taped on the wall next to the terminal instead.
