## NATIONAL SEMICONDUCTOR CORPORATION

## A Corporate Dedication to Quality and Reliability

National Semiconductor is an industry leader in the manufacture of high quality, high reliability integrated circuits. We have been the leading proponent of driving down IC defects and extending product lifetimes. From raw material through product design, manufacturing and shipping, our quality and reliability is second to none.

We are proud of our success...it sets a standard for others to achieve. Yet, our quest for perfection is ongoing so that you, our customer, can continue to rely on National Semiconductor Corporation to produce high quality products for your design systems.

Charles E. Sporck
President, Chief Executive Officer National Semiconductor Corporation

## Wir fühlen uns zu Qualität und Zuverlässigkeit verpflichtet

National Semiconductor Corporation ist führend bei der Harstellung von integrierten Schaltungen hoher Qualität und hoher Zuverlässigkeit. National Semiconductor war schon immer Vorreiter, wenn es galt, die Zahl von IC Ausfällen zu verringern und die Lebensdauern von Produkten zu verbessern. Vom Rohmaterial Uber Entwurf und Herstellung bis zur Auslieferung, die Qualität und die Zuverlässigkeit per Produkte von National Semiconductor sind unübertroffen.

Wir sind stolz auf unseren Erfolg, der Standards setzt, die für andere erstrebenswert sind. Auch ihre Ansprüche steigen ständig, Sie als unser Kunde können sich auch weiterhin auf National Semiconductor verlassen.

## La Qualité et La Fiabilité: <br> Une Vocation Commune Chez National Semiconductor Corporation

National Semiconductor Corporation c'est l'un des leaders industriels qui fabrique des circuits intégrés d'une très grande qualité et d'une fiabilité exceptionnelle. National a été le premier à vouloir faire chuter le nombre de circuits intégrés defectueux et a augmenter la durée de vie des produits. Depuis les matières premières, en passant par la conception du produit sa fabrication et son expédition, partout la qualité et la fiabilité chez National sont sans équivalents.
Nous sommes fiers de notre succès et le standard ainsi défini devrait devenir l'objectif à atteindre par les autres sociéteś. Et nous continuons à vouloir faire progresser notre recherche de la perfection; il en résulte que vous, qui êtes notre client, pouvez toujours faire confiance à National Semiconductor Corporation, en produisànt des systèmes d'une très grande qualité standard.

## Un Impegno Societario di Qualità e Affidabilità

National Semiconductor Corporation è un'industria al vertice nella costruzione di circuiti integrati di altà qualità ed affidabilità. National è stata il principale promotore per l'abbattimento della difettosità dei circuiti integrati e per l'allungamento della vita dei prodotti. Dal materiale grezzo attraverso tutte le fasi di progettazione, costruzione e spedizione, la qualità e affidabilità National non è seconda a nessuno.

Noi siamo orgogliosi del nostro successo che fissa per gli altri un traguardo da raggiungere. II nostro desiderio di perfezione è d'altra parte illimitato e pertanto tu, nostro cliente, puoi continuare ad affidarti a National Semiconductor Corporation per la produzione dei tuoi sistemi con elevati livelli di qualità.

## LIFE SUPPORT POLICY

## NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

## Introduction

National Semiconductor Corporation's CMOS Databook contains the industry's most comprehensive collection of high-performance CMOS products avallable today. Our early commitment to microCMOS technology has made possible the development of a broad spectrum of advanced devices that will simplify your design and ensure state-of-the-art systems.
microCMOS technology describes National's array of small-geometry, silicon-gate, oxide-isolated processes used to build the high-performance products found in this book. Using N - or P -well substrates and multiple-layer metal or polysilicon-interconnect structures, microCMOS processes produce feature sizes of $3.0,2.0$, or 1.5 microns, with submicron feature sizes in development. (For more detailed information, specific device family introductions are provided at the beginning of each section.) microCMOS accounts for nearly half of National's current research and development effort, and this commitment will increase through the '80s.

New microCMOS products are being introduced constantly. If you don't find what you need in this book, please contact your local National Semiconductor sales office or distributor.

## Einführung

Das. CMOS-Datenbuch von National Semiconductor enthält in seiner neuesten Ausgabe (1984) das umfangreichste Typenspektrum an Hochleistungs-CMOS-Produkten, die derzelt in der Industrie erhältilch sind. Die frühzeitige Entscheidung von National Semiconductor für die sogenannte "microCMOS"Technologle ermöglichte die Entwicklung eines breiten Spektrums fortschrittlicher Bauelemente, die den Entwurf moderner Systeme sehr erleichtern.
microCMOS-Technologie ist eln Oxid-Isolierter Herstel-lungs-proze $\beta$ für Silizium-Gate-CMOS-Strukturen mit kleinen Geometrien, der die Produktion der Im Datenbuch beschriebenen Hochleistungs-Bauelememte ermöglicht. Auf P-oder N-Wannen-Substraten erzeugt der microCMOSProze $\beta$ Strukturen mit Abmessungen von 3,0, 2,0 oder $1,5 \mu \mathrm{~m}$ und mit Polysilizium-oder Metallverbindungen. (Detailinformationen enthalten die technischen Angaben zu einer speziellen Bauelemetefamilie, die zu Reginn eines jeden Abschnittes zu finden sind.) SubmikrometerStrukturen befinden sich derzeit in Entwicklung.

Für die microCMOS-Technologle wendet Natlonal Semiconductor derzelt etwa die Hälfte der Forschungsund Entwicklungs-Mittel auf. Dleser Antell wird In den nächsten Jahren noch zunehmen.

Neue microCMOS-Produkte werden laufend auf den Markt gebracht. Sollten spezielle Bauelementetypen, die noch nicht im Katalog enthalten sind, benötigt werden, ertellen der örtliche Distributor oder das nächstgelegene Verkaufsburo von National Semiconductor gerne Auskunft.

## Introduction

National Semiconductor Corporation a réuni dans son CMOS Databook la plus complète collection de l'industrie de circuits CMOS hautes performances actuellement disponible. National, en s'engageant depuis un certain temps dans la technologie microCMOS, a rendu possible le développement d'une large gamme de circuits performants qui simplifieront la conception de vos circuits tout en les faisant bénéficier des meilleures performances.

Les circuits performants décrits dans cet ouvrage mettent en oeuvre la technologie microCMOS National (cellules de faible géométrie MOS). Le procédé microCMOS, dispose de substrats $N$ ou $P$, de structures multi-couches métalliques et interconnexions multiples, il permet d'obtenir des canaux de 3, 2 or 1,5 microns. National travaille actuellement sur des cellules inférieures au micron. (Pour une information plus detaillée, consulter au début de chaque chapitrê, les instructions particulières à chaque famille de circuits.) National consacre pratiquement la moitié de ses efforts en recherche et developpement à la technologie microCMOS. Cet effort ira sans cesse en s'accroissant au cours des années 1980.

De nouveaux produits microCMOS sortent sans cesse. Si vous ne trouvez pas dans cet ouvrage ce dont vous avez besoin, veuillez contacter votre ingénieur commercial ou votre distributeur National Semiconductor.

## Introduzione

II databook sui dispositivi CMOS Della National Semiconductor Corporation contiene una tra le piu vaste gamme dl prodotti CMOS ad alta tecnologia attualmente disponibili per l'Industria.

II nostro recente impegno verso la tecnologia CMOS. Ha reso posibilie lo sviluppo di una vastissima gamma di dispositivi avanzatl che semplificheranno I vostrl progetti e garantiranno al vostri sistemi una tra le piu avanzate tecnologie. La tecnologia CMOS della Natlonal comprende gll array a canale stretto, i silicon gate ed i processi con isolamento ad ossido usatl per la fabbricazione di prodott| per applicazionl ad alto livello che trovere in questo calalogo.

Usando substrati drogati n oppure pe stratificazioni di alluminio a diversi livelli, oppure connessioni a polysillcio, i processI CMOS hanno in produzione canali di dimensioni da 3.0-2.0-1,5 microns, con dimensioni di submicron in sviluppo. (Per informazione pio dettagliate, indicazione specifiche per ogni famiglia sono fornito all'inizio di clascun paragrafo).
La Natlonal dedica la meta del proprl sforzi per la ricercae lo sviluppo della tecnologia CMOS, e questo impegno crescera senza dubblo nel corso degll anni 80.
I nuovi dispositivi CMOS vengono introdotti constantemente; nel caso in cul non trovaste clo di cul avete bisogno In questo catalogo, mettetevi in contatto con l'ufficio di zona della National oppure con il distributore di zona.

MM54HC563/MM74HC563 TRI-STATE Octal D-Type Latch with Inverted Outputs ..... $1-302$
MM54HC573/MM74HC573 TRI-STATE Octal D-Type Latch ..... $1-308$
MM54HCT373/MM74HCT373 TRI-STATE Octal D-Type Latch ..... $1-503$
MM54HCT533/MM74HCT533 TRI-STATE Octal D-Type Latch ..... 1-511
MM54HCT563/MM74HCT563 TRI-STATE Octal D-Type Latch with Inverted Outputs ..... 1-523
MM54HCT573/MM74HCT573 TRI-STATE Octal D-Type Latc̣h ..... 1.529
Multiplexers/Demultiplexers
MM54HC151/MM74HC151 8-Channel Multiplexer ..... 1-113
MM54HC153/MM74HC153 Dual 4-Input Multiplexer ..... $1-116$
MM54HC157/MM74HC157 Quad 2-Input Multiplexer ..... 1-123
MM54HC158/MM74HC158 Quad 2-Input Multiplexer (Inverted Output) ..... 1-123
MM54HC251/MM74HC251 8-Channel TRI-STATE Multiplexer ..... 1-215
MM54HC253/MM74HC253 Dual 4-Channel TRI-STATE Multiplexer ..... 1-218
MM54HC257/MM74HC257 Quad 2-Channel TRI-STATE Multiplexer ..... $1-221$
MM54HC298/MM74HC298 Quad 2-Input Multiplexers with Storage ..... 1-247
MM54HC354/MM74HC354 8-Channel TRI-STATE Multiplexers with Latches ..... 1-256
MM54HC356/MM74HC356 8-Channel TRI-STATE Multiplexers with Latches ..... 1-256
MM54HC4051/MM74HC4051 8-Channel Analog Multiplexer ..... 1-377
MM54HC4052/MM74HC4052 Dual 4-Channel Analog Multiplexer ..... 1-377
MM54HC4053/MM74HC4053 Triple 2-Channel Analog Multiplexer ..... 1-377
MM54HC4351/MM74HC4351 8-Channel Analog Multiplexer with Latches ..... $1-403$
MM54HC4352/MM74HC4352 Dual 4-Channel Analog Multiplexer with Latches ..... 1-403
MM54HC4353/MM74HC4353 Triple 2-Channel Analog Multiplexer with Latches ..... $1-403$
MM54HCT157/MM74HCT157 Quad 2-Input Multiplexer ..... 1-455
MM54HCT158/MM74HCT158 Quad 2-Input Multiplexer (Inverted Output) ..... $1-455$
MM54HCT257/MM74HCT257 Quad 2-ChanneI TRI-STATE Multiplexer ..... $1-493$
Multivibrators
MM54HC123A/MM74HC123A Dual Retriggerable Monostable Multivibrator ..... 1.83
MM54HC221A/MM74HC221A Dual Non-Retriggerable Monostable Multivibrator ..... 1-188
MM54HC423A/MM74HC423A Dual Retriggerable Monostable Multivibrator ..... 1.281
MM54HC4046/MM74HC4046 CMOS Phase Lock Loop ..... 1-365
MM54HC4538/MM74HC4538 Dual Retriggerable Monostable Multivibrator ..... 1.414
Registers
MM54HC164/MM74HC164 8-Bit Serial-In Parallel-Out Shift Register . ..... 1-132
MM54HC165/MM74HC165 Parallel-In Serial-Out 8-Bit Shift Register ..... 1-135
MM54HC166/MM74HC166 8.Bit Serial or Parallel Input/Serial Output Shift Register with Reset ..... 1-139

## Table of Contents ${ }_{\text {(Continued) }}$

MM54HC194/MM74HC194 4-Bit Bidirectional Shift Register ..... 1-180
MM54HC195/MM74HC195 4-Bit Parallel Shift Register ..... 1-184
MM54HC299/MM74HC299 8-Bit TRI-STATE Universal Shift Register ..... 1-251
MM54HC589/MM74HC589 8-Bit Shift Register with Input Latches and TRI-STATE Serial Output ..... $1-314$
MM54HC595/MM74HC595 8-Bit Shift Registers with Output Latches ..... 1-324
MM54HC597/MM74HC597 8-Bit Shift Registers with Input Latches ..... 1-329
MM54HCT164/MM74HCT164 8-Bit Serial-In/Parallel-Out Shift Register ..... 1-462
MM54HCT166/MM74HCT166 8-Bit Serial or Parallel Input/Serial Output Shift Register with Reset ..... 1-465
MM54HCT299/MM74HCT299 8-Bit TRI-STATE Universal Shift Register ..... 1.499
MM54HCT323/MM74HCT323 8-Bit TRI-STATE Universal Shift Register ..... 1-501
Transceivers
MM54HC242/MM74HC242 Inverting Quad TRI-STATE Transceiver ..... 1-202
MM54HC243/MM74HC243 Quad TRI-STATE Transceiver ..... 1-202
MM54HC245/MM74HC245 Octal TRI-STATE Transceiver ..... 1-211
MM54HC543/MM74HC543 Octal Registered Transceiver ..... 1-298
MM54HC544/MM74HC544 Octal Registered Transceiver ..... 1-299
MM54HC550/MM74HC550 Octal Registered Transceiver with Status Flags ..... 1.300
MM54HC551/MM74HC551 Octal Registered Inverting Transceiver with Status Flags ..... $1-301$
MM54HC640/MM74HC640 Inverting Octal TRI-STATE Transceiver ..... 1-334
MM54HC643/MM74HC643 True-Inverting Octal TRI-STATE Transceiver ..... $1-334$
MM54HC646/MM74HC646 Non-Inverting Octal Bus Transceiver/Registers ..... $1-338$
MM54HC648/MM74HC648 Inverting Octal Bus Transceiver/Registers ..... $1-338$
MM54HCT245/MM74HCT245 Octal TRI-STATE Transceiver ..... $1-490$
MM54HCT543/MM74HCT543 Octal Registered Transceiver ..... $1-519$
MM54HCT544/MM74HCT544 Octal Registered Inverting Transceiver ..... 1-520
MM54HCT550/MM74HCT550 Octal Registered Transceiver with Status Flags ..... $1-521$
MM54HCT551/MM74HCT551 Octal Registered Inverting Transceiver with Status Flags ..... 1.522
MM54HCT640/MM74HCT640 Inverting Octal TRI-STATE Transceiver ..... 1-540
MM54HCT643/MM74HCT643 True-Inverting ..... 1-540
Section 2—Semi-Custom Circuits
Gate Arrays
SCXSeries of 2-Micron and 3-Micron CMOS Gate Arrays ..... 2-4
SCX6324 microCMOS 2.4k Gate Array NSO00U Option U'ser's Note ..... 2.5
SCX CMOS Gate Array Family Applications Guide ..... 2-11
Section 3-LSI/VLSI CMOS
Oscillators/Dividers
MM5368 CMOS Oscillator Divider Circuit ..... 3-3
MM5369Series 17-Stage Oscillator/Divider ..... 3-6
MM53107 Series 17-Stage Oscillator/Divider ..... 3-9
Other (LSI, VLSI CMOS)
MM74HC942 300 Baud Modem (+5, -5 Volt Supply) ..... $3-38$
MM74HC943 300 Baud Modem (5 Volt Supply) ..... 3-44

## Table of Contents ${ }_{\text {(Continued) }}$

Real-Time Clocks
MM58167A Microprocessor Real-Time Clock ..... 3-11
MM58174A Microprocessor-Compatible Real-Time Clock ..... $3-19$
MM58274 Microprocessor-Compatible Real-Time Clock ..... 3-26
Section 4—Filters
Monolithic
MF4 4th Order Switched Capacitor Butterworth Lowpass Filter ..... 4.5
MF5 Universal Monolithic Switched Capacitor Filter ..... $4-12$
MF6 6th Order Switched Capacitor Butterworth Lowpass Filter ..... 4.13
MF10 Universal Monolithic Dual Switched Capacitor Filter ..... 4-21
Section 5-Telecommunications Circuits
Modems
TP3310/TP3311/TP3320/TP3321 Monolithic 1200-600/150-75-5 Bit/s CMOS FSK Modem Family ..... 5-63
Switching and Transmission
TP3020/TP3021 Monolithic CODECs ..... 5-3
TP3040/TP3040A PCM Monolthic Filter ..... 5-12
TP3051/TP3056 Monolithic Parallel Data Interface CMOS CODEC/FILTER Family ..... 5-19
TP3052/TP3053/TP3054/TP3057 Monolithic Serial Interface CMOS CODEC/FILTER Family ..... 5-30
TP3064/TP3067 Monolithic Serial Interface CMOS CODEC/FILTER Combos ..... 5-43
TP3155 Time Slot Assignment Circuit ..... 5-56
TP5116A/TP5156A Monolithic CODECs ..... 5-86
Telephone Components
TP5087/TP5092/TP5094/TP5380 DTMF (TOUCH-TONE) Generators ..... 5.74
TP5088 DTMF Generator for Binary Data ..... 5.78
TP5089 DTMF (TOUCH-TONE) Generator ..... 5.82
TP5600/TP5605/TP5610/TP5615 Ten-Number Repertory Pulse Dialers ..... 5-92
TP5650/TP5660 Ten-Number Repertory DTMF Generators ..... 5.98
TP50981/TP50981A, TP50982/TP50982A, TP50985/TP50985A Push Button Pulse Dialer Circuits ..... 5-103
TP53130 DTMF (TOUCH-TONE) Generator with Binary Data and Keypad Interface ..... 5-109
TP53190 Push-Button Pulse Dialer ..... 5.114
Section 6-Converters
Analog to Digital
ADC0801/ADC0802/ADC0803/ADC0804/ADC0805 8-Bit $\mu$ P Compatible A/D Converters ..... 6.5
ADC0808/ADC0809 8-Bit $\mu$ P Compatible A/D Converters with 8-Channel Multiplexer ..... 6.37
ADC0816/ADC0817 8-Bit $\mu$ PCompatible A/D Converters with 16-Channel Multiplexer ..... 6.48
ADC0820 8-Bit High Speed $\mu$ P Compatible AID Converter with Track/Hold Function ..... 6.59
ADC $0829 \mu$ P Compatible 8-Bit A/D with 11-Channel Multiplexer/Digital Input ..... 6.74
ADC0831/ADC0832/ADC0834/ADC0838 8-Bit Serial I/O A/D Converters with Multiplexer Options ..... 6.82
ADC0833 8-Bit Serial I/O A/D Converter with 4-Channel Multiplexer ..... 6.106

## Table of Contents ${ }_{\text {(Continued) }}$

ADC0844 8-Bit $\mu$ P Compatible A/D Converter with 4-Channel Multiplexer ..... 6.123
ADC1001/ADC1021 10-Bit $\mu$ P Compatible A/D Converters ..... 6.138
ADC3511/ADC3711 31/2 Digit Microprocessor Compatible A/D Converter ..... 6.145
ADD3501 31/2 Digit DVM with Multiplexed 7-Segment Output ..... 6-153
ADD3701 33/4 Digit DVM with Multiplexed 7-Segment Output ..... 6-162
Digital to Analog
DAC0830/DAC0831/DAC0832 8-Bit $\mu$ P Compatible, Double-Buffered D to A Converters ..... 6.172
DAC1000/DAC1001/DAC1002/DAC1006/DAC1007/DAC1008 $\mu$ P Compatible, Double-Buffered D to A Converters ..... 6-188
DAC1020/DAC1021/DAC1022 10-Bit Binary Multiplying D/A Converters ..... 6.210
DAC1220/DAC1221/DAC1222 12-Bit Binary Multiplying D/A Converters ..... 6.210
DAC1208/DAC1209/DAC1210, DAC1230/DAC1231/DAC1232 12-Bit, $\mu \mathrm{P}$ Compatible, Double-Buffered D to A Converters ..... 6.220
DAC1218/DAC1219 12-Bit Binary Multiplying D/A Converter ..... 6-235
Section 7—Data Communications Support
Transmilters
MM58220 Asynchronous Low Power Transmitter Remote Controller ..... 7.3
MM58250 Infrared Transmitter ..... 7.4
Section 8—Display Controllers/Drivers
Display Drivers
MM5452/MM5453 Liquid Crystal Display Drivers ..... 8-3
MM5483 Liquid Crystal Display Driver ..... 8.9
MM58201 Multiplexed LCD Driver ..... 8-12
MM58241 High Voltage Display Driver ..... 8-17
MM58248 High Voltage Display Driver ..... 8.22
MM58270 Display Driver ..... 8 -27
MM58341 High Voltage Display Driver ..... 8-29
MM58348 High Voltage Display Driver ..... 8.34
MM58438 32-Bit LCD Display Driver ..... 8.39
MM58538 Multiplexed LCD Driver ..... 8-43
MM58539 Multiplexed LCD Driver ..... 8-47
MM58540 Multiplexed LCD Driver ..... 8-51
MM58548 Multiplexed LCD Driver ..... 8-55
MM54HC4511/MM74HC4511 BCD-to-7 Segment Latch/Decoder/Driver ..... 8-59
MM54HC4543/MM74HC4543 BCD-to-7 Segment Latch/Decoder/Driver for Liquid Crystal Displays ..... 8-64
Section 9—RAMs
CMOS Static
NMC6164 $8192 \times 8$-Bit Static RAM ..... 9-3
Section 10—PROMs
EPROM CMOS/NMOS
NMC27C16 16,384-Bit ( $2048 \times 8$ ) UV Erasable CMOS PROM ..... 10-3
NMC27C32 32,768-Bit ( $4096 \times 8$ ) UV Erasable CMOS PROM ..... $10 \cdot 10$

MM5368 CMOS Oscillator Divider Circuit ..... 3.3
MM5369 Series 17-Stage Oscillator/Divider ..... 3.6
MM5452 Liquid Crystal Display Driver ..... 8.3
MM5453 Liquid Crystal Display Driver ..... 8-3
MM5483 Liquid Crystal Display Driver ..... 8.9
MM53107 Series 17-Stage Oscillator/Divider ..... 3.9
MM58167A Microprocessor Real-Time Clock ..... 3-11
MM58174A Microprocessor Compatible Real-Time Clock ..... 3-19
MM58201 Multiplexed LCD Driver ..... 8-12
MM58220 Asynchronous Low Power Transmitter Remote Controller ..... 7.3
MM58241 High Voltage Display Driver ..... 8-17
MM58248 High Voltage Display Driver ..... 8-22
MM58250 Infrared Transmitter ..... $7-4$
MM58270 Display Driver ..... 8-27
MM58274 Microprocessor-Compatible Real-Time Clock ..... 3-26
MM58341 High Voltage Display Driver ..... 8.29
MM58348 High Voltage Display Driver ..... 8.34
MM58438 32-Bit LCD Display Driver ..... 8-39
MM58538 Multiplexed LCD Driver ..... 8-43
MM58539 Multiplexed LCD Driver ..... 8-47
MM58540 Multiplexed LCD Driver ..... 8-51
MM58548 Multiplexed LCD Driver ..... 8-55
MM54HC00/MM74HC00 Quad 2-Input NAND Gate ..... $1-5$
MM54HC02/MM74HC02 Quad 2-Input NOR Gate ..... 1.8
MM54HC03/MM74HC03 Quad 2-Input Open Drain NAND Gate ..... $1-11$
MM54HC04/MM74HC04 Hex Inverter ..... 1-14
MM54HC08/MM74HC08 Quad 2-Input AND Gate ..... $1-17$
MM54HC10/MM74HC10 Triple 3-Input NAND Gate ..... 1-20
MM54HC11/MM74HC11 Triple 3-Input AND Gate ..... $1-23$
MM54HC14/MM74HC14 Hex Inverting Schmitt Trigger ..... $1-26$
MM54HC20/MM74HC20 Dual 4-Input NAND Gate ..... $1-29$
MM54HC27/MM74HC27 Triple 3-Input NOR Gate ..... 1-32
MM54HC30/MM74HC30 8-Input NAND Gate ..... 1-35

## Alphanumeric Index ${ }_{\text {(Continued) }}$

MM54HC32/MM74HC32 Quad 2-Input OR Gate ..... 1.38
MM54HC42/MM74HC42 BCD-to-Decimal Decoder ..... $1-41$
MM54HC51/MM74HC51 Dual AND-OR-Invert Gate ..... $1-44$
MM54HC58/MM74HC58 Dual AND-OR Gate ..... 1.44
MM54HC73/MM74HC73 Dual J-K Flip-Flops with Clear ..... $1-47$
MM54HC74/MM74HC74 Dual D Fiip-Flop with Preset and Clear ..... 1-51
MM54HC75/MM74HC75 4-Bit Bistable Latch with Q and $\bar{Q}$ Output ..... 1-54
MM54HC76/MM74HC76 Dual J-K Flip-Flops with Preset and Clear ..... 1-57.
MM54HC85/MM74HC85 4-Bit Magnitude Comparator ..... 1-61
MM54HC86/MM74HC86 Quad 2-Input Exclusive OR Gate ..... $1-65$
MM54HC107/MM74HC107 Dual J-K Flip-Flops with Clear ..... $1-68$
MM54HC109/MM74HC109 Dual J-位Flip-Flops with Preset and Clear ..... $1-72$
MM54HC112/MM74HC112 Dual J-K Flip-Flops with Preset and Clear ..... 1.75
MM54HC1.13/MM74HC113 Dual J-K Flip-Flops with Preset ..... $1-79$
MM54HC123A/MM74HC123A Dual Retriggerable Monostable Multivibrator ..... 1.83
MM54HC125/MM74HC125 TRI-STATE Quad Buffers ..... $1-88$
MM54HC126/MM74HC126 TRI-STATE Quad Buffers ..... 1.88
MM54HC132/MM74HC132 Quad 2-Input NAND Schmitt Trigger ..... 1.91
MM54HC133/MM74HC133 13-Input NAND Gate ..... 1.94
MM54HC137/MM74HC137 3-to-8 Line Decoder with Address Latches (Inverted Output) ..... 1-97
MM54HC138/MM74HC138 3-to-8 Line Decoder ..... 1-101
MM54HC139/MM74HC139 Dual 2-to-4 Line Decoder ..... $1-104$
MM54HC147/MM74HC147 10-to-4 Line Priority Encoder ..... 1-107
MM54HC149/MM74HC149 8-to-8 Line Priority Encoder ..... $1-110$
MM54HC151/MM74HC151 8-Channel Multiplexer ..... $1-113$
MM54HC153/MM74HC153 Dual 4-Input Multiplexer ..... 1-116
MM54HC154/MM74HC154 4-to-16 Line Decoder ..... 1-119
MM54HC157/MM74HC157 Quad 2-Input Multiplexer ..... 1-123
MM54HC158/MM74HC158 Quad 2-Input Multiplexer (Inverted Output) ..... 1-123
MM54HC160/MM74HC160 Synchronous Decade Counter ..... 1-127
MM54HC161/MM74HC161 Synchronous Binary Counter ..... 1-127
MM54HC162/MM74HC162 Synchronous Decade Counter ..... 1-127
MM54HC163/MM74HC163 Synchronous Binary Counter ..... 1-127
MM54HC164/MM74HC164 8-Bit Serial-In Parallel-Out Shift Register ..... 1-132
MM54HC165/MM74HC165 Parallel-In Serial-Out 8-Bit Shift Register ..... $1-135$
MM54HC166/MM74HC166 8-Bit Serial or Parallel Input/Serial Output Shift Register with Reset ..... 1-139
MM54HC169/MM74HC169 4-Bit Up/Down Synchronous Binary Counter ..... 1-144
MM54HC173/MM74HC173 TRI-STATE Quad D Flip-Flop ..... $1-146$
MM54HC174/MM74HC174 Hex D Flip-Flops with Clear ..... 1-150
MM54HC175/MM74HC175 Quad D-Type Flip-Flop with Clear ..... $1-153$
MM54HC181/MM74HC181 Arithmetic Logic Units/Function Generators ..... 1-157
MM54HC182/MM74HC182 Look-Ahead Carry Generator ..... 1-165
MM54HC190/MM74HC190 Synchronous Decade Up/Down Counters with Mode Control ..... 1.168
MM54HC191/MM74HC191 Synchronous Binary Up/Down Counters with Mode Control ..... 1-168
MM54HC192/MM74HC192 Synchronous Decade Up/Down Counters ..... $1-174$
MM54HC193/MM74HC193 Synchronous Binary Up/Down Counters ..... 1-174
MM54HC194/MM74HC194 4-Bit Bidirectional Shift Register ..... $1-180$
MM54HC195/MM74HC195 4-Bit Parallel-In Shift Register ..... $1-184$
MM54HC221A/MM74HC221A Dual Non-Retriggerable Monostable Multivibrator ..... 1-188

## Alphanumeric Index (Continued)

MM54HC237/MM74HC237 3-to-8 Decoder with Address Latches ..... 1-193
MM54HC240/MM74HC240 Inverting Octal TRI-STATE Buffer ..... 1-197
MM54HC241/MM74HC241 Octal TRI-STATE Buffer ..... 1.197
MM54HC242/MM74HC242 Inverting Quad TRI-STATE Transceiver ..... $1-202$
MM54HC243/MM74HC243 Quad TRI-STATE Transceiver ..... 1-202
MM54HC244/MM74HC244 Octal TRI-STATE Buffer ..... $1-207$
MM54HC245/MM74HC245 Octal TRI.STATE Transceiver ..... 1-211
MM54HC251/MM74HC251 8-Channel TRI-STATE Multiplexer ..... 1 -215
MM54HC253/MM74HC253 Dual 4-Channel TRI-STATE Multiplexer ..... 1.218
MM54HC257/MM74HC257 Quad 2-Channel TRI-STATE Multiplexer ..... 1.221
MM54HC259/MM74HC259 8-Bit Addressable Latch/3-to-8 Line Decoder ..... $1-224$
MM54HC266/MM74HC266 Quad 2-Input Exclusive NOR Gate ..... 1.228
MM54HC273/MM74HC273 Octal D Flip.Flops with Clear ..... 1.231
MM54HC280/MM74HC280 9-Bit Odd/Even Parity Generator/Checker ..... 1-234
MM54HC283/MM74HC283 4-Bit Binary Adder with Fast Carry ..... 1.237
MM54HC292/MM74HC292 Programmable Frequency Dividers/Digital Timers ..... 1-241
MM54HC294/MM74HC294 Programmable Frequency Dividers/Digital Timers ..... 1-241
MM54HC298/MM74HC298 Quad 2-Input Multiplexers with Storage ..... 1.247
MM54HC299/MM74HC299 8-Bit TRI-STATE Universal Shift Register ..... 1-251
MM54HC354/MM74HC354 8-Channel TRI-STATE Multiplexers with Latches ..... 1-256
MM54HC356/MM74HC356 8-Channel TRI-STATE Multiplexers with Latches ..... $1-256$
MM54HC365/MM74HC365 Hex TRI-STATE Buffer ..... 1-263
MM54HC366/MM74HC366 Inverting Hex TRI-STATE Buffer ..... 1-263
MM54HC367/MM74HC367 Hex TRI-STATE Buffer ..... 1-263
MM54HC368/MM74HC368 Inverting Hex TRI-STATE Buffer ..... 1-263
MM54HC373/MM74HC373 TRI-STATE Octal D-Type Latch ..... $1-270$
MM54HC374/MM74HC374 TRI-STATE Octal D-Type Flip-Flop ..... 1-273
MM54HC390/MM74HC390 Dual 4-Bit Decade Counter ..... $1-276$
MM54HC393/MM74HC393 Dual 4-Bit Binary Counter ..... 1.276
MM54HC423A/MM74HC423A Dual Retriggerable Monostable Multivibrator ..... 1-281
MM54HC521/MM74HC521 8-Bit Magnitude Comparator (Equality Detector) ..... 1-286
MM54HC533/MM74HC533 TRI-STATE Octal D-Type Latch with Inverted Outputs ..... $1-289$
MM54HC534/MM74HC534 TRI-STATE Octal D-Type Flip-Flop with Inverted Outputs ..... 1-292
MM54HC540/MM74HC540 inverting Octal TRI-STATE Buffer ..... 1-295
MM54HC541/MM74HC541 Octal TRI-STATE Buffer ..... 1-295
MM54HC543/MM74HC543 Octal Registered Transceiver ..... 1-298
MM54HC544/MM74HC544 Octal Registered Transceiver ..... 1-299
MM54HC550/MM74HC550 Octal Registered Transceiver with Status Flags ..... $1-300$
MM54HC551/MM74HC551 Octal Registered Inverting Transceiver with Status Flags ..... 1-301
MM54HC563/MM74HC563 TRI-STATE Octal D-Type Latch with Inverted Outputs ..... 1.302
MM54HC564/MM74HC564 TRI-STATE Octal D-Type Flip.Flop with Inverted Outputs ..... 1 1-305
MM54HC573/MM74HC573 TRI-STATE Octal D-Type Latch ..... 1-308
MM54HC574/MM74HC574 TRI-STATE Octal D-Type Flip.Flop ..... 1-311
MM54HC589/MM74HC589 8-Bit Shift Registers with Input Latches and TRI-STATE Serial Output ..... $1-314$
MM54HC590/MM74HC590 8-Bit Binary Counter with TRI-STATE Output Register ..... 1-319
MM54HC592/MM74HC592 8-Bit Binary Counter with Input Register ..... 1.321
MM54HC593/MM74HC593 8-Bit Binary Counter with Bidirectional Input Register/ Counter Outputs ..... 1-321
MM54HC595/MM74HC595 8-Bit Shift Registers with Output Latches ..... 1.324

## Alphanumeric Index (Continued)

MM54HC597/MM74HC597 8-Bit Shift Registers with Input Latches ..... 1.329
MM54HC640/MM74HC640 Inverting Octal TRI-STATE Transceiver ..... 1-334
MM54HC643/MM74HC643 True-Inverting Octal TRI-STATE Transceiver ..... 1.334
MM54HC646/MM74HC646 Non-Inverting Octal Bus Transceiver/Registers ..... 1-338
MM54HC648/MM74HC648 Inverting Octal Bus Transceiver/Registers ..... 1.338
MM54HC688/MM74HC688 8-Bit Magnitude Comparator (Equality Detector) ..... 1.345
MM54HC4002/MM74HC4002 Dual 4-Input NOR Gate ..... $1-348$
MM54HC4016/MM74HC4016 Quad Analog Switch ..... 1-351
MM54HC4017/MM74HC4017 Decade Counter/Divider with 10 Decoded Outputs ..... 1-356
MM54HC4020/MM74HC4020 14-Stage Binary Counter ..... 1-360
MM54HC4024/MM74HC4024 7-Stage Binary Counter ..... $1-360$
MM54HC4040/MM74HC4040 12-Stage Binary Counter ..... $1-360$
MM54HC4046/MM74HC4046 CMOS Phase Lock Loop ..... 1.365
MM54HC4049/MM74HC4049 Hex Inverting Logic Level Down Converter ..... $1-374$
MM54HC4050/MM74HC4050 Hex Logic Level Down Converter ..... 1-374
MM54HC4051/MM74HC4051 8-Channel Analog Multiplexer ..... 1-377
MM54HC4052/MM74HC4052 Dual 4-Channel Analog Multiplexer ..... $1-377$
MM54HC4053/MM74HC4053 Triple 2-Channel Analog Multiplexer ..... 1-377
MM54HC4060/MM74HC4060 14-Stage Binary Counter ..... 1.383
MM54HC4066/MM74HC4066 Quad Analog Switch ..... 1-387
MM54HC4075/MM74HC4075 Triple3-Input OR Gate ..... $1-392$
MM54HC4078/MM74HC4078 8-Input NOR/OR Gate ..... $1-395$
MM54HC4316/MM74HC4316 Quad Analog Switch with Level Translator ..... $1-398$
MM54HC4351/MM74HC4351 8-Channel Analog Multiplexer with Latches ..... 1.403
MM54HC4352/MM74HC4352 Dual 4-Channel Analog Multiplexer with Latches ..... 1.403
MM54HC4353/MM74HC4353 Triple 2-Channel Analog Multiplexer with Latches ..... 1.403
MM54HC4511/MM74HC4511 BCD-to-7 Segment Latch/Decoder/Driver ..... 8-59
MM54HC4514/MM74HC4514 4-to-16 Line Decoder with Latch ..... 1.410
MM54HC4538/MM74HC4538 Dual Retriggerable Monostable Multivibrator ..... $1-414$
MM54HC4543/MM74HC4543 BCD-to-7 Segment Latch/Decoder/Driver for Liquid Crystal Displays ..... 8-64
MM74HC942 300 Baud Modem ( +5 , -5 Volt Supply) ..... 3.38
MM74HC943 300 Baud Modem (5 Volt Supply) ..... 3-44
MM54HCT00/MM74HCT00 Quad 2-Input NAND Gate ..... 1-420
MM54HCT04/MM74HCT04 Hex Inverter ..... $1-423$
MM54HCT05/MM74HCT05 Hex Inverter (Open Drain) ..... $1-426$
MM54HCT34/MM74HCT34 Non-Inverter ..... $1-428$
MM54HCT74/MM74HCT74 Dual D Flip-Flop with Preset and Clear ..... 1.431
MM54HCT76/MM74HCT76 Dual J.K Flip-Flops with Preset and Clear ..... $1-434$
MM54HCT107/MM74HCT107 Dual J.K Flip-Flops with Clear ..... $1-437$
MM54HCT109/MM74HCT109 Dual J-信 Flip-Flops with Preset and Clear ..... $1-440$
MM54HCT112/MM74HCT112 Dual J-K Flip-Flops with Preset and Clear ..... $1-434$
MM54HCT138/MM74HCT138 3-to-8 Line Decoder ..... 1.443
MM54HCT139/MM74HCT139 Dual 2-to-4 Line Decoder ..... $1-446$
MM54HCT149/MM74HCT149 8-Line to 8-Line Priority Encoder ..... 1.449
MM54HCT155/MM74HCT155 Dual 2-to-4 Line Decoder/Demultiplexers ..... 1-452
MM54HCT157/MM74HCT157 Quad 2-Input Multiplexer ..... 1-455
MM54HCT158/MM74HCT158 Quad 2-Input Multiplexer (Inverted Output) ..... $1-455$
MM54HCT160/MM74HCT160 Synchronous Decade Counter with Asynchronous Clear ..... 1-459
MM54HCT161/MM74HCT161 Synchronous Binary Counter with Asynchronous Clear ..... $1-459$
MM54HCT162/MM74HCT162 Synchronous Decade Counter with Synchronous Clear ..... $1-459$

## Alphanumeric Index (Continued)

MM54HCT163/MM74HCT163 Synchronous Binary Counter with Synchronous Clear ..... 1.459
MM54HCT164/MM74HCT164 8-BitSerial-In/Parallel-Out Shift Register ..... $1-462$
MM54HCT166/MM74HCT166 8-Bit Serial or Parallel Input/Serial Output Shift Register with Reset ..... $1-465$
MM54HCT169/MM74HCT169 4-Bit Up/Down Synchronous Binary Counter ..... 1-470
MM54HCT174/MM74HCT174 Hex DFlip.Flops with Clear ..... 1-472
MM54HCT191/MM74HCT191 Synchronous Binary Up/Down Counters with Mode Control ..... 1-475
MM54HCT193/MM74HCT193 Synchronous Binary Up/Down Counters ..... $1-481$
MM54HCT240/MM74HCT240 Inverting Octal TRI-STATE Buffer ..... 1.486
MM54HCT241/MM74HCT241 Octal TRI-STATE Buffer ..... $1-486$
MM54HCT244/MM74HCT244 Octal TRI-STATE Buffer ..... $1-486$
MM54HCT245/MM74HCT245 Octal TRI-STATE Transceiver ..... 1-490
MM54HCT257/MM74HCT257 Quad 2-Channel TRI-STATE Multiplexer ..... 1-493
MM54HCT273/MM74HCT273 Octal D Flip-Flop with Clear ..... 1-496
MM54HCT299/MM74HCT299 8-Bit TRI-STATE Universal Shift Register ..... 1-499
MM54HCT323/MM74HCT323 8-Bit TRI-STATE Universal Shift Register ..... $1-501$
MM54HCT373/MM74HCT373TRI-STATE Octal D-Type Latch ..... 1.503
MM54HCT374/MM74HCT374TRI-STATE Octal D.Type Flip-Flop ..... $1-503$
MM54HCT521/MM74HCT521 8-Bit Magnitude Comparator (Equality Detector) ..... 1.508
MM54HCT533/MM74HCT533TRI-STATE Octal D-Type Latch ..... 1.511
MM54HCT534/MM74HCT534 TRI-STATE Octal D-Type Flip-Flop ..... 1.511
MM54HCT540/MM74HCT540 Inverting Octal TRI-STATE Buffer ..... 1.515
MM54HCT541/MM74HCT541 Inverting Octal TRI-STATE Buffer ..... 1.515
MM54HCT543/MM74HCT543 Octal Registered Transceiver ..... 1.519
MM54HCT544/MM74HCT544 Octal Registered Inverting Transceiver ..... 1.520
MM54HCT550/MM74HCT550 Octal Registered Transceiver with Status Flags ..... 1.521
MM54HCT551/MM74HCT551 Octal Registered Inverting Transceiver with Status Flags ..... 1-522
MM54HCT563/MM74HCT563 TRI-STATE Octal D-Type Latch with Inverted Outputs ..... 1-523
MM54HCT564/MM74HCT564 TRI-STATE Octal D-Type Flip-Flop with Inverted Outputs ..... 1.526
MM54HCT573/MM74HCT573 TRI-STATE Octal D-Type Latch ..... 1 1-529
MM54HCT574/MM74HCT574 TRI-STATE Octal D-Type Flip-Flop ..... 1.532
MM54HCT590/MM74HCT590 8-Bit Binary Counter with TRI-STATE Output Register ..... 1.535
MM54HCT592/MM74HCT592 8-Bit Binary Counter with Input Register ..... 1.537
MM54HCT593/MM74HCT593 8-Bit Binary Counter with Bidirectional Input Register/ Counter Outputs ..... 1.537
MM54HCT640/MM74HCT640 Inverting Octal TRI-STATE Transceiver ..... 1.540
MM54HCT643/MM74HCT643 True-Inverting Octal TRI-STATE Transceiver ..... 1.540
MM54HCT688/MM74HCT688 8-Bit Magnitude Comparator(Equality Detector) ..... 1-543
MM54HCU04/MM74HCU04 Hex Inverter ..... 1-546
MM82PC08 8-Bit Bidirectional Transceiver ..... 12.25
MM82PC12 8-Bit Input/Output Port ..... 12.31

## Parts Listing

National manufactures a complete line of metal gate CMOS logic products (CD4000,54C/74C, and 74PC). A list of these products follows. Our $54 \mathrm{HC} / 74 \mathrm{HC}$ products offer improved performance and appear in Section 1 in datasheet form for your information and convenience.

Section 1 54HC/74HC High Speed CMOS

## Introduction

National has been a supplier of CMOS logic since 1970, starting with the CD4000 family. National next introduced the 54/74C Series-replicating, in CMOS, the "footprints" (pinouts) and functions of the standard TTL bipolar 7400 Logic Family.
Until recently, however, high-speed CMOS systems had to include some bipolar logic ICs as well because CMOS logic was not fast enough. The use of bipolar logic meant that system designers had interface and power dissipation problems.

## AN ADVANCED, HIGH-SPEED CMOS LOGIC FAMILY

National has introduced a new, high-speed CMOS Logic Family-the 54/74HC Series.* Many industry watchers are calling it the most significant development in logic since TTL.

This new series is the first broad-based CMOS logic family to attain true bipolar (74LS) speed performance, while maintaining the many advantages of CMOS: high noise immunity, wide power supply range, wide range of operating temperature, and low power dissipation. In addition, this CMOS family offers 74LS equivalent pinouts and output drive ( 4 mA sink and source).

National is also supplying some of the most popular CD4000 devices in this new high-speed technology. As an example, the CD4060 will be offered as the MM74HC4060. Some new functions not currently available in any logic family (MM74HC9XX parts) will also be offered and the MM74HCTXXX designation is used for a group of special TTL buffers. (The inputs of these buffers meet TTL logic voltage level specs.)

## HOW SPEED HAS BEEN IMPROVED

National uses self-aligned silicon-gate CMOS with oxide isolation to obtain speed and density advantages in these logic circuits.

To understand how this works, look at a cross-section of a logic inverter in metal-gate CMOS, as shown in Figure 1-1. Notice that all the key parasitics have been drawn on this diagram. The extra $\mathrm{P}^{+}$diffusion necessary around the N -channel device and the extra $\mathrm{N}^{+}$diffusion around the P-channel device are the guard rings (channel stoppers) that are necessary to prevent parasitic MOS transistors between devices. The length indicated for laying out a logic inverter (one N-channel and one P-channel device) is about 125 microns for a typical metal-gate process.

FIGURE 1-1. A Cross-Section of a Logic Inverter In Metal-Gate CMOS

Now, look at the SI-gate CMOS inverter shown in Figure 1-2. The 125 -micron distance noted previously for a simple logic Inverter is reduced to only 64 microns.

With the oxide isolation performing the channel stop functlon:

- The need for extra channel stop diffuslons is eliminated.
- The $\mathrm{P}^{+}$and $\mathrm{N}^{+}$diffusions can now butt directly against the oxide (no space is required).
- The geometries and spacings overall can be made smaller because of shallower junction depths.

Therefore, a $2: 1$ reduction in the parasitic capacitances can be obtained with this new CMOS process. Since the gate is self-aligned to the source and drain (i.e., the gate actually defines the separation between the source and drain regions), the gate overlap capacitance is also significantly reduced.

This decreased capacitance, combined with the $4: 1 \mathrm{in}$ crease in the gain of the silicon-gate transistors (the silicon-gate devices have better gain due to the shorter channel length, thinner gate oxide, and lower threshold voltage), explains the speed improvement of eight to ten times over the earlier metal-gate CMOS logic.

## SPECIFICATIONS FOR THE 54/74HC LOGIC FAMILY

A 2 V to 6 V operating range was chosen for the new $54 / 74 \mathrm{HC}$ family. The 6 V maximum limit results because of transistor drain-to-source punchthrough with the short channel lengths (further reductlons in channel length will bring about the new 2 V to 3 V power supply voltage standard for VLSI products).

There are specifications on the maximum allowable DC output current for all of the outputs as well as for the $V_{C C}$ and ground pins. These limits exist because of the potential for metal migration... a phenomenon that occurs if DC current limits are exceeded for long time intervals. Limiting the maximum DC current flow increases the reliability of the circuit.

The input logic levels for this family are similar to standard CD4000 and 54/74C CMOS: 1.0 V and 3.5 V , using a 5 V power supply. Over the complete supply voltage range the worst-case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ input levels are typically $70 \%$ and $20 \%$ of $\mathrm{V}_{\mathrm{Cc}}$, respectively. In addition, to facilitate interfacing from TTL and TTL compatible circuits to $54 / 74 \mathrm{HC}$, a sub-family of devices (designated MM54HCT/MM74HCT) is also offered. These devices are designed and specified for TTL input logic voltage levels.

FIGURE 1.2. A Cross-Section of a Logic Inverter In microCMOS

## COMPARING OUTPUT CURRENT SINK AND SOURCE

These new 74HC products can drive capacitive loads with the same response times as the 74LS products. The reasons for this can be seen by looking at the comparisons of the output current sink and source capabilities of these logic families as shown in Figures 1-3 and 1-4.

Here the new CMOS output stages can be seen to compare favorably with those of the 74LS bipolar logic family. It is these large output currents that provide the ability to rapidly drive load capacitance. This also requires the same attention as 74LS to PC board layouts and power supply bypass capacitors.

For complete details and characteristics of the 54/74HC family, see National's 1983 High.Speed CMOS Databook, which also contains numerous application notes.

FIGURE 1-3. Comparing the Output Sink Current Capabilities of 74HC and 74LS

## CMOS AND BIPOLAR DESIGN

Bipolar designers who have never used CMOS must remember one important rule: never leave an input pin floating. Unused inputs must be tied to $\mathrm{V}_{\mathrm{CC}}$, ground, or an output. If left floating, an input can charge up (due to leakage current flow) to the threshold voltage level and turn ON both the N-channel and P-channel transistors at the same time. This will cause the IC to draw potentially destructive DC currents from $V_{C C}$ to ground. This problem is aggravated by the large current capability of this new logic family.

FIGURE 1-4. Comparing the Output Source Current Capabilities of 74HC and 74LS

## MM54HC00/MMM74HC00 Quad 2-Input NAND Gate

## General Description

These NAND gates utilize microCMOS Technology, 3.5 mi cron silicon gate $P$-well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. All gates have buffered outputs. All devices have high noise immunity and the ability to drive 10 LS-TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 8 ns
- Wide power supply range: 2-6V
- Low quiescent current: $20 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads

| ICC | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & I_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 2.0 | 20 | 40 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{I}_{\mathrm{N}}$, $\mathrm{I}_{\mathrm{CC}}$, and $\mathrm{l}_{\mathrm{Oz}}$ occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC02/MM74HC02 Quad 2-Input NOR Gate

## General Description

These NOR gates utilize microCMOS Technology, 3.5 mi cron silicon gate P -well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. All gates have buffered outputs, providing high noise immunity and the ability to drive 10 LS-TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 8 ns
- Wide power supply range: 2-6V
- Low quiescent supply current: $20 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- High output current: 4 mA minimum

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC03/MM74HC03 Quad 2-input Open Drain NAND Gate

## General Description

These NAND gates utilize microCMOS Technology, 3.5 mi cron silicon gate $P$-well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. All gates have buffered outputs. All devices have high noise immunity and the ability to drive 10 LS-TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard $54 \mathrm{LS} / 74 \mathrm{LS}$ logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.
As with standard $54 \mathrm{HC} / 74 \mathrm{HC}$ push-pull outputs there are diodes to both $V_{C C}$ and ground. Therefore the output should not be pulled above $V_{C C}$ as it would be clamped to one diode voltage above $\mathrm{V}_{\mathrm{CC}}$. This diode is added to enhance electrostatic protection.

## Features

■ Typical propagation delay: 12 ns

- Wide power supply range: 2-6V
- Low quiescent current: $20 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of $10 \mathrm{LS}-T \mathrm{TL}$ loads

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{H}}$ and $\mathrm{V}_{\mathbb{I L}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. ( $T$ he $\mathrm{V}_{\mathbb{H}}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{I}_{\mathrm{N}}$. $\mathrm{I}_{\mathrm{CC}}$, and $\mathrm{I}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## AC Electrical Characteristics

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## NMM54HC04/MM74HC04 Hex Inverter

## General Description

These Inverters utilize microCMOS Technology, 3.5 mictor silicon gate P -well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits.
The MM54HC04/MM74HC04 is a triple buffered inverter. It has high noise immunity and the ability to drive 10 LSTTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard 54LS/74LS logic famlly. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

Typical propagation delay: 8 ns

- Fan out of 10 LS-TTL loads
a Quiescent power consumption: $10 \mu \mathrm{~W}$ maximum at room temperature
- Typical input current: $10^{-5} \mu \mathrm{~A}$

## MM54HC08/MM74HC08 Quad 2-Input AND Gate

## General Description

These AND gates utilize microCMOS Technology, 3.5 mi cron silicon gate P -well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. The HCO8 has buffered outputs, providing high noise immunity and the ability to drive 10 LS -TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 7 ns (tphL) 12 ns (tpLH)
- Fanout of 10 LS-TTL loads
- Quiescent power consumption: $2 \mu \mathrm{~A}$ maximum at room temperature
- Typical input current: $10^{-5} \mu \mathrm{~A}$

| ICC | Maximum Quiescent Supply Current | $\begin{aligned} & \mathrm{V}_{\mathrm{IN}}=\mathrm{V}_{\mathrm{CC}} \text { or } \mathrm{GND} \\ & \mathrm{I}_{\mathrm{OUT}}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0V |  | 2.0 | 20 | 40 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages $\left(\mathrm{V}_{\mathrm{OH}}\right.$, and $\mathrm{VOL}_{\mathrm{O}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{H}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{H}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (l) $\mathrm{I}_{\mathrm{CC}}$, and lOZ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC10/MM74HC10 Triple 3-Input NAND Gate

## General Description

These NAND gates utilize microCMOS Technology, 3.5 mi cron silicon gate P -well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. All gates have buffered outputs. All devices have high noise immunity and the ability to drive 10 LS-TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 8 ns
- Wide power supply range: 2-6V
- Low quiescent current: $20 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads

| Icc | Maximum Quiescent Supply Current | $\begin{aligned} & \mathrm{V}_{\mathrm{IN}}=\mathrm{V}_{\mathrm{CC}} \text { or } \mathrm{GND} \\ & \mathrm{I}_{\mathrm{OUT}}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 2.0 | 20 | 40 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J" package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN, $\mathrm{I}_{\mathrm{CC}}$, and $\mathrm{l}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

National Semiconductor

## MM54HC11／MM74HC11 Triple 3－Input AND Gate

## General Description

These AND gates utilize microCMOS Technology， 3.5 mi － cron silicon gate P －well CMOS，to achieve operating speeds similar to LS－TTL gates with the low power consumption of standard CMOS integrated circuits．All gates have buffered outputs，providing high noise immunity and the ability to drive 10 LS －TTL loads．The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is func－ tionally as well as pin－out compatible with the standard 54LS／74LS logic family．All inputs are protected from dam－ age due to static discharge by internal diode clamps to $V_{C C}$ and ground．

## Features

－Typical propagation delay： 12 ns
－Wide power supply range：2－6V
－Low quiescent current： $20 \mu \mathrm{~A}$ maximum（ 74 HC series）
－Low input current： $1 \mu \mathrm{~A}$ maximum
－Fanout of 10 LS－TTL loads

## MM54HC14/MM74HC14 Hex Inverting Schmitt Trigger

## General Description

The MM54HC14/MM74HC14 utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS, to achieve the low power dissipation and high noise immunity of standard CMOS, as well as the capability to drive 10 LS-TTL loads.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{\mathrm{CC}}$ and ground.

## Features

■ Typical propagation delay: 13 ns

- Wide power supply range: 2-6V
- Low quiescent current: $20 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads
- Typical hysteresis voltage: 0.9 V at $V_{C C}=4.5 \mathrm{~V}$

## Connection Diagram

## MM54HC20/MM74HC20 Dual 4-Input NAND Gate

## General Description

These NAND gates utilize microCMOS Technology, 3.5 mi cron silicon gate P-Well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. All gates have buffered outputs. All devices have high noise immunity and the ability to drive 10 LS-TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 12 ns
- Wide power supply range: 2-6V
- Low quiescent current: $20 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwisa specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J"package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OU}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{H}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{HH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{I}_{\mathrm{N}}$, icc, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

MM54HC27/MM74HC27 Triple 3-Input NOR Gate

## General Description

These NOR gates utilize microCMOS Technology, 3.5 mi cron silicon gate P-well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. All gates have buffered outputs, providing high noise immunity and the ability to drive $10 \mathrm{LS}-\mathrm{TTL}$ loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- Typical Propagation Delay: 8 ns
- Wide Operating Supply Voltage Range: 2-6V

■ Low Input Current: < $1 \mu \mathrm{~A}$
■ Low Quiescent Supply Current: $20 \mu \mathrm{~A}$ maximum (74HC series)

- Fanout of 10 LS-TTL Loads

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC30/MM74HC30 8-Input NAND Gate

## General Description

This NAND gate utilizes microCMOS Technology, 3.5 mi cron silicon gate P -well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. This device has high noise immunity and the ability to drive 10 LS-TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{C}}$ and ground.

## Features

- Typical propagation delay: 20 ns
- Wide power supply range: 2-6V
n Low quiescent current: $20 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads

Note 1: Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " $\mathrm{J}^{\circ}$ packdge: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{VOH}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (l/N, ${ }^{\mathrm{I}} \mathrm{CC}$, and $\mathrm{I}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

National Semiconductor

MR54HC32/MM74HC32 Quad 2-Input OR Gate

## General Description

These OR gates utilize microCMOS Technology, 3.5 micron silicon gate P -well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. All gates have buffered outputs, providing high noise immunity and the ability to drive 10 LS-TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard 54LS/ 74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 10 ns

Bi Wide power supply range: 2-6V

- Low. quiescent current: $20 \mu \mathrm{~A}$ maximum ( $\mathbf{7 4 \mathrm { HC }}$ series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads

## Connection Diagram

54 HC 32 (J) $\quad \mathbf{7 4 H C 3 2}$ (J,N)

## Logic Diagram

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J" package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $V_{I H}$ and $V_{I L}$ occur at $V_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $V_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $l_{I N}$, $I_{\mathrm{CC}}$, and $\mathrm{l}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## AC Electrical Characteristics

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

MM54HC42／MM74HC42 BCD－to－Decimal Decoder

## General Description

This decoder utilizes microCMOS Technology， 3.5 micron silicon gate P－well CMOS．Data on the four input pins select one of the 10 outputs corresponding to the value of the BCD number on the inputs．An output will go low when selected， otherwise it remains high．If the input data is not a valid BCD number all outputs will remain high．The circuit has high noise immunity and low power consumption usually associ－ ated with CMOS circuitry，yet also has speeds comparable to low power Schottky TTL（LS－TTL）circuits，and is capable of driving 10 LS －TTL equivalent loads．
All inputs are protected from damage due to static dis－ charge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground．

## Connection Diagram

## Features

－Typical propagation delay： 15 ns
m．Wide supply range：2V－6V
■ Low quiescent current： $80 \mu \mathrm{~A}(74 \mathrm{HC})$
a Fanout of 10 LS－TTL loads

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Uniess otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J" package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{VOH}_{\mathrm{OH}}$, and $\mathrm{VOU}_{\mathrm{O}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. $I_{\mathrm{CC}}$, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

microCMOS

## MM54HC51/MM74HC51 Dual AND-OR-Invert Gate MM54HC58/MM74HC58 Dual AND-OR Gate

## General Description

These gates utilize microCMOS Technology, 3.5 micron silicon gate P -well CMOS, to achieve operating speeds similar. to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. All gates have buffered outputs, providing high noise immunity and the ability to drive 10 LS-TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard 54LS/ 74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

■ Typical propagation delay: 10 ns

- Wide power supply range: 2-6V
- Low quiescent supply current: $20 \mu \mathrm{~A}$ maximum (74 series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- High output current: 4 mA minimum

## MM54HC73/MM74HC73 Dual J-K Flip-Flops with Clear

## General Description

These J-K Flip-Flops utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS. They possess the high noise immunity and low power dissipation of standard CMOS integrated circuits. These devices can drive 10 LSTTL loads.
These flip-flops are edge sensitive to the clock input and change state on the negative going transition of the clock pulse. Each one has independent, J, K, CLOCK, and CLEAR inputs and Q and $\overline{\mathrm{Q}}$ outputs. CLEAR is independent of the clock and accomplished by a low level on the input.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family.

## Connection Diagram

| ICC | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & I_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 4.0 | 40 | 80 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{VOH}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{1 H}$ and $\mathrm{V}_{\mathbb{I L}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{1 H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. Icc, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC74/MM74HC74

Dual D Flip-Flop with Preset and Clear

## General Description

The MM54HC74/MM74HC74 utilizes microCMOS Technology, 3.5 micron silicon gate P -well CMOS, to achieve operating speeds similar to the equivalent LS-TTL part. It possesses the high noise immunity and low power consumption of standard CMOS integrated circuits, along with the ability to drive 10 LS-TTL loads.
This flip-flop has independent data, preset, clear, and clock inputs and $Q$ and $\bar{Q}$ outputs. The logic level present at the data input is transferred to the output during the positive-going transition of the clock pulse. Preset and clear are independent of the clock and accomplished by a low level at the appropriate input.
Connection Diagram

## Dual-In-Line Package

TOP VIEW
TL/F/5106-1

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{C}}$ and ground.

## Features

- Typical propagation delay: 20 ns
- Wide power supply range: 2-6V
- Low quiescent current: $40 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads

## Truth Table

| Inputs |  |  |  | Outputs |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| PR | CLR | CLK | D | Q | $\overline{\mathbf{a}}$ |
| L | H | X | X | H | L |
| H | L | X | X | L | H |
| L | L | X | X | $H^{*}$ | $H^{*}$ |
| H | H | $\uparrow$ | H | H | L |
| H | H | $\uparrow$ | L | L | H |
| H | H | L | X | QO | $\overline{\text { Qo }}$ |

Note: $\mathrm{Q} 0=$ the level of Q before the indicated input conditions were established.

- This configuration is nonstable; that is, it will not persist when preset and clear inputs return to their inactive (high) level.

Logic Diagram

Absolute Maximum Ratings (Notes $1 \& 2$ )
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) DC Input Voltage ( $\mathrm{V}_{\mathrm{IN}}$ )
-0.5 to +7.0 V

DC Output Voltage (VOUT)
Clamp Diode Current ( $\mathrm{I}_{\mathrm{K}}, \mathrm{l}_{\mathrm{OK}}$ ) DC Output Current, per pin (lout)
DC V $C C$ or GND Current, per pin (ICC)
-1.5 to $\mathrm{V}_{\mathrm{CC}}+1.5 \mathrm{~V}$
-0.5 to $V_{C C}+0.5 \mathrm{~V}$ $\pm 20 \mathrm{~mA}$ $\pm 25 \mathrm{~mA}$ $\pm 50 \mathrm{~mA}$
Storage Temperature Range (TSTG)
Power Dissipation (PD) (Note 3)
Lead Temperature (TL) (Soldering 10 seconds) $260^{\circ} \mathrm{C}$

Operating Conditions

| ICC | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & I_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 4.0 | 40 | 80 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{l}_{\mathrm{I}}$, ICC, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

AC Electrical Characteristics $\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}, \mathrm{t}_{\mathrm{t}}=\mathrm{t}_{\mathrm{t}}=6$ ns

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+l c c \mid V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+l_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC75/MM74HC75 <br> 4-Bit Bistable Latch with $\mathbf{Q}$ and $\bar{Q}$ Output

## General Description

This 4-Bit Latch utilizes microCMOS Technology, 3.5 micron silicon gate P -well CMOS. To achieve the high noise immunity and low power consumption normally associated with standard CMOS integrated circuits. These devices can drive 10 LS-TTL loads.
This latch is ideally suited for use as temporary storage for binary information processing, input/output, and indicator units. Information present at the data (D) input is transferred to the $Q$ output when the enable $(G)$ is high. The $Q$ output will follow the data input as long as the enable remains high. When the enable goes low, the information that was present at the data input at the time the transition occurred is retained at the Q output until the enable is permitted to go high again.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical operating frequency: 50 MHz
m Typical propagation delay: 12 ns
- Wide operating supply voltage range: 2-6V

■ Low input current: $<1 \mu \mathrm{~A}$

- Low quiescent supply current: $80 \mu \mathrm{~A}$ maximum (74HC series)
m Fanout of 10 LS-TTL loads

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{I}_{\mathrm{N}}$. $\mathrm{I}_{\mathrm{cc}}$, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

AC Electrical Characteristics $V_{C C}=5 \mathrm{~V}, \mathrm{~T}_{A}=25^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=15 \mathrm{pF} ; \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC76/MM74HC76 Dual J-K Flip-Flops with Preset and Clear

## General Description

These high speed ( 30 MHz minimum) J-K Flip-Flops utilize microCMOS Technology, 3.5 micron silicon P-well CMOS, to achieve, the low power consumption and high noise immunity of standard CMOS integrated circuits, along with the ability to drive 10 LS-TTL loads.
Each flip-flop has independent $J, K$, PRESET, CLEAR, and CLOCK inputs and $Q$ and $\bar{Q}$ outputs. These devices are edge sensitive to the clock input and change state on the negative going transition of the clock pulse. Clear and preset are independent of the clock and accomplished by a low logic level on the corresponding input.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 16 ns
- Wide operating voltage range
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $40 \mu \mathrm{~A}$ maximum ( 74 HC series)
- High output drive: 10 LS-TTL loads

Typical Applications

N Bit presettable ripple counter with enable and reset

TL/F/5074-4

N Blt parallel load/serial load shift register with clear

TL/F/5074-5

## General Description

The MM54HC85/MM74HC85 is a 4-bit magnitude comparator that utilizes microCMOS Technology, 3.5 micron silicon gate P -well CMOS. It is designed for high speed comparison of two four bit words. This circuit has eight comparison inputs, 4 for each word; three cascade inputs $(A<B, A>B$, $A=B)$; and three decision outputs ( $A<B, A>B, A=B$ ). The result of a comparison is indicated by a high level on one of the decision outputs. Thus it may be determined whether one word is "greater than," "less than," or "equal to" the other word. 'By connecting the outputs of the least significant stage to the cascade inputs of the next stage, words of greater than four bits can be compared. In addition the least significant stage must have a high level applied to the $A=B$ input, and a low level to the $A<B$, and $A>B$ inputs.

The comparator's outputs can drive 10 low power Schottky TTL (LS-TTL) equivalent loads, and is functionally, and pin equivalent to the 54LS85/74LS85. All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 27 ns
- Wide operating voltage range: 2-6V

■ Low input current: $1 \mu \mathrm{~A}$ maximum

- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)

■ Output drive capability: 10 LS-TTL loads

| $\mathrm{I}_{\mathrm{N}}$ | Maximum Input Current | $\mathrm{V}_{\mathrm{IN}}=\mathrm{V}_{\text {CC }}$ or GND | 6.0 V |  | $\pm 0.1$ | $\pm 1.0$ | $\pm 1.0$ | $\mu \mathrm{A}$ |
| Icc | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & I_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages $\left(\mathrm{V}_{\mathrm{OH}}\right.$, and $\left.\mathrm{V}_{\mathrm{O}}\right)$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{i H}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{l}_{\mathrm{I}}$, $I_{\mathrm{CC}}$, and $\mathrm{l}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

AC Electrical Characteristics $\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=15 \mathrm{PF}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{t}}=6$ ns

$I_{S}=C_{P D} V_{C C} f+I_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## Typical Application

## MM54HC86／MM74HC86 Quad 2－Input Exclusive OR Gate

## General Description

This EXCLUSIVE OR gate utilizes microCMOS Technology， 3.5 micron silicon gate $P$－well CMOS，to achieve operating speeds similar to equivalent LS．TTL gates while maintaining the low power consumption and high noise immunity char－ acteristic of standard CMOS integrated circuits．These gates are fully buffered and have a fanout of 10 LS－TTL loads．The MM54HC／74HC logic family is functionally as well as pin out compatible with the standard 54LS／74LS logic family．All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground．

## Features

－Typical propagation delay： 9 ns
－Wide operating voltage range：2－6V
－Low input current： $1 \mu \mathrm{~A}$ maximum
■ Low quiescent current： $20 \mu \mathrm{~A}$ maximum（ 74 series）
－Output drive capability： 10 LS－TTL loads

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specifled all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages $\left(\mathrm{V}_{\mathrm{OH}}\right.$, and $\mathrm{V}_{\mathrm{OL}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{H}}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{I}_{\mathrm{N}}$, Icc, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC107/MM74HC107 Dual J-K Flip-Flops with Clear

## General Description

These J-K Flip-Flops utilize microCMOS Technology, 3.5 micron silicon gate P -well CMOS, to achieve the high noise immunity and low power dissipation of standard CMOS integrated circuits. These devices can drive 10 LS-TTL loads. These flip-flops are edge sensitive to the clock input and change state on the negative going transition of the clock pulse. Each one has independent J, K, CLOCK, and CLEAR inputs and $Q$ and $\bar{Q}$ outputs. CLEAR is independent of the clock and accomplished by a low level on the input.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Connection Diagram

Dual-In-Line Package

## Features

- Typical propagation delay: 16 ns - Wide operating voltage range: 2-6V

Low input current: $1 \mu \mathrm{~A}$ maximum

- Low quiescent current: $40 \mu \mathrm{~A}$ ( 74 HC series)

High output drive: 10 LS-TTL loads .

## Truth Table

| Inputs |  |  |  | Outputs |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

## MM54HC109/MM74HC109 Dual J-K Flip-Flops with Preset and Clear

## General Description

These J-K FLIP-FLOPS utilize microCMOS Technology, 3.5 micron silicon gate P-Well CMOS to achieve the low power consumption and high noise immunity of standard CMOS integrated circuits, along with the ability to drive 10 LS-TTL loads.
Each flip flop has independent $J, \bar{K}$ PRESET, CLEAR and CLOCK inputs and $Q$ and $\bar{Q}$ outputs. These devices are edge sensitive to the clock input and change state on the positive going transition of the clock pulse. Clear and preset are independent of the clock and accomplished by a low logic level on the corresponding input.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 20 ns
- Wide operating voltage range: 2-6V
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $40 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Output drive capability: 10 LS-TTL loads

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{H}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{I H}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. Icc, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC112／MM74HC112

## Dual J－K Flip－Flops with Preset and Clear

## General Description

These high speed（ 30 MHz minimum）J－K Flip－Flops utilize microCMOS Technology， 3.5 micron silicon gate $P$－well CMOS，to achieve the low power consumption and high noise immunity of standard CMOS integrated circuits，along with the ability to drive 10 LS－TTL loads．
Each flip－flop has independent J，K，PRESET，CLEAR，and CLOCK inputs and $Q$ and $\bar{Q}$ outputs．These devices are edge sensitive to the clock input and change state on the negative going transition of the clock pulse．Clear and pre－ set are independent of the clock and accomplished by a low logic level on the corresponding input．

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin－ out compatible with the standard 54LS／74LS logic family． All inputs are protected from damage due to static dis－ charge by internal diode clamps to $V_{C C}$ and ground．

## Features

－Typical propagation delay： 16 ns
－Wide operating voltage range
－Low input current： $1 \mu \mathrm{~A}$ maximum
－Low quiescent current： $40 \mu \mathrm{~A}$（ 74 HC series）
－High output drive： 10 LS－TTL loads

## Truth Table

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J" package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{I}_{\mathrm{N}}$, Icc, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

AC Electrical Characteristics $\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+I_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+I_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

Typical Applications
N Bit presettable ripple counter with enable and reset

N Bit parallel load/serial load shift register with clear

TL/F/5074-5

National Semiconductor

## MM54HC113／MM74HC113 <br> Dual J－K Flip－Flops with Preset

## General Description

These high speed J－K Flip－Flops utilize microCMOS Tech－ nology， 3.5 micron silicon gate P－well CMOS，to achieve the high noise immunity and low power dissipation of standard CMOS integrated circuits．These devices can drive 10 LS－ TTL loads．
These flip－flops are edge sensitive to the clock input and change state on the negative going transition of the clock pulse．Each one has independent J，K，CLOCK，and PRE－ SET inputs and Q and $\overline{\mathrm{Q}}$ inputs．PRESET is independent of the clock and accomplished by a low level on the input．
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin－ out compatible with the standard 54LS／74LS logic family． All inputs are protected from damage due to static dis－ charge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground．

## Features

－Typical propagation delay： 16 ns
－Wide operating voltage range：2－6V
n Low input current： $1 \mu \mathrm{~A}$ maximum
－Low quiescent current： $40 \mu \mathrm{~A}$（ 74 HC series）
migh output drive： 10 LS－TTL loads

## MM54HC123A/MM74HC123A Dual Retriggerable Monostable Multivibrator

## General Description

The MM54/74HC123A high speed monostable multivibrators (one shots) utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS. They feature speeds comparable to low power Schottky TTL circuitry while retaining the low power and high noise immunity characteristic of CMOS circuits.
Each multivibrator features both a negative, $A$, and a positive, B, transition triggered input, either of which can be used as an inhibit input. Also included is a clear input that when taken low resets the one shot. The ' HCl 23 can be triggered on the positive transition of the clear while $A$ is held low and $B$ is held high.
The 'HC123A is retriggerable. That is it may be triggered repeatedly while their outputs are generating a pulse and the pulse will be extended.
Pulse width stability over a wide range of temperature and supply is achieved using linear CMOS techniques. The output pulse equation is simply: $\mathrm{PW}=\left(\mathrm{R}_{\mathrm{EXT}}\right)\left(\mathrm{C}_{\mathrm{EXT}}\right)$; where PW is in seconds, R is in ohms, and C is in farads. All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 40 ns
- Wide power supply range: 2V-6V
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads
- Simple pulse width formula $T=R C$
- Wide pulse range: 400 ns to $\infty$ (typ)
- Part to part variation: $\pm 5 \%$ (typ)
- Schmitt Trigger A \& B inputs enable infinite signal input rise and fall times.

Note 1: Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation Temperature Derating:
Plastic " $N$ " Package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$
Ceramic " $J$ " Package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst-case output voltages ( $\mathrm{VOH}_{\mathrm{OH}}, \mathrm{VOU}_{\mathrm{O}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst-case $V_{I H}$ and $V_{I L}$ occur at $V_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst-case leakage current (liN , Icc, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## Logic Diagram

## Theory of Operation

## TRIGGER OPERATION

As shown in Figure 1 and the logic diagram before an input trigger occurs，the one shot is in the quiescent state with the Q output low，and the timing capacitor $\mathrm{C}_{\text {EXT }}$ completely charged to $V_{C C}$ ．When the trigger input $A$ goes from $V_{C C}$ to GND（while inputs $B$ and clear are held to $V_{C C}$ ）a valid trig－ ger is recognized，which turns on comparator C1 and N－ Channel transistor N1©．At the same time the output latch is set．With transistor N 1 on，the capacitor $\mathrm{C}_{\mathrm{EXT}}$ rapidly dis－ charges toward GND until $\mathrm{V}_{\text {REF }}$ is reached．At this point the output of comparator C 1 changes state and transistor N1 turns off．Comparator C1 then turns off while at the same time comparator C2 turns on．With transistor N1 off，the ca－ pacitor $C_{E X T}$ begins to charge through the timing resistor， $R_{E X T}$ ，toward $V_{C C}$ ．When the voltage across $C_{E X T}$ equals $V_{\text {REF2 }}$ ，comparator C2 changes state causing the output latch to reset（ $Q$ goes low）while at the same time disabling comparator C 2 ．This ends the timing cycle with the monosta－ ble in the quiescent state，waiting for the next trigger．
A valid trigger is also recognized when trigger input B goes from GND to $V_{C C}$（while input $A$ is at GND and input clear is at $\mathrm{V}_{\mathrm{CC}}{ }^{(2)}$ ．）The＇ $\mathrm{HC1} 123$ can also be triggered when clear goes from GND to $V_{C C}$（while $A$ is at GND and $B$ is at $\mathrm{V}_{\mathrm{CC}}{ }^{(6)}$ ．）
It should be noted that in the quiescent state $\mathrm{C}_{\text {EXT }}$ is fully charged to $\mathrm{V}_{C C}$ causing the current through resistor $\mathrm{R}_{\text {EXT }}$ to be zero．Both comparators are＂off＂with the total device current due only to reverse junction leakages．An added feature of the＇ HCl 123 is that the output latch is set via
the input trigger without regard to the capacitor voltage． Thus，propagation delay from trigger to $Q$ is independent of the value of $\mathrm{C}_{\text {EXT }}$ ．Rext，or the duty cycle of the input wave－ form．

## RETRIGGER OPERATION

The＇HC123 is retriggered if a valid trigger occurs（3）fol－ lowed by another trigger（c）before the Q output has re－ turned to the quiescent（zero）state．Any retrigger，after the timing node voltage at pin or has begun to rise from $V_{\text {REF }}$ ， but has not yet reached $V_{\text {REF2 }}$ ，will cause an increase in output pulse width $T$ ．When a valid retrigger is initiated（©）， the voltage at the $R / C_{E X T}$ pin will again drop to $V_{\text {REF1 }}$ be－ fore progressing along the RC charging curve toward $V_{C C}$ ． The Q output will remain high until time $T$ ，after the last valid retrigger．

## RESET OPERATION

These one shots may be reset during the generation of the output pulse．In the reset mode of operation，an input pulse on clear sets the reset latch and causes the capacitor to be fast charged to $\mathrm{V}_{\mathrm{CC}}$ by turning on transistor Q1（5）．When the voltage on the capacitor reaches $V_{\text {REF2 }}$ ，the reset latch will clear and then be ready to accept another pulse．If the clear input is held low，any trigger inputs that occur will be inhibited and the Q and $\overline{\mathrm{Q}}$ outputs of the output latch will not change．Since the $Q$ output is reset when an input low level is detected on the Clear input，the output pulse $T$ can be made significantly shorter than the minimum pulse width specification．

TL／F／5206－10
Note：R and C are not subjected to temperature．The C is polypropolyne．

National Semiconductor

## MM54HC125/MM74HC125 <br> MM54HC126/MM74HC126 TRI-STATE® QUAD BUFFERS

## General Description

These are general purpose TRI-STATE high speed non-inverting buffers utilizing microCMOS technology, 3.5 micron silicon gate $P$-well CMOS. They have high drive current outputs which enable high speed operation even when driving large bus capacitances. These circuits possess the low power dissipation of CMOS circuitry, yet have speeds comparable to low power Schottky TTL circuits. Both circuits are capable of driving up to 15 low power Schottky inputs.
The MM54HC125/MM74HC125 require the TRI-STATE control input C to be taken high to put the output into the high impedance condition, whereas the MM54HC126/ MM74HC126 requires the control input to be low to put the output into high impedance.
All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 13 ns
- Wide operating voltage range: 2-6V
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC )
- Fanout of 15 LS-TTL loads

## DC Electrical Characteristics (Note 4)

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Uniess otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \dot{\mathrm{~mW}} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $V_{I H}$ and $V_{I L}$ occur at $V_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (l|N, $I^{\mathrm{I} C}$, and $\mathrm{l}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC132/MM74HC132 Quad 2-Input NAND Schmitt Trigger

## General Description

The MM54HC132/MM74HC132 utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS, to achieve the low power dissipation and high noise immunity of standard CMOS, as well as the capability to drive 10 LS-TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 12 ns

■ Wide power supply range: $2 \mathrm{~V}-6 \mathrm{~V}$

- Low quiescent current: $20 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads
- Typical hysteresis voltage: 0.9 V at $\mathrm{V}_{\mathrm{CC}}=4.5 \mathrm{~V}$.

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC133/MM74HC133 13-Input NAND Gate

## General Description

This NAND gate utilizes microCMOS Technology, $3.5 \mathrm{mi}-$ cron silicon gate P -well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. All gates have buffered outputs. All devices have high noise immunity and the ability to drive 10 LS-TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 20 ns
- Wide power supply range: 2-6V
- Low quiescent current: $20 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OU}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. Icc , and $\mathrm{I}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## AC Electrical Characteristics

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+l_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+l_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC137/MM74HC137 3-to-8 Line

## General Description

This device utilizes microCMOS Technology, 3.5 micron silicon gate P -well CMOS, to implement a three-to-eight line decoder with latches on the three address inputs. When GL goes from low to high, the address present at the select inputs ( $A, B$ and $C$ ) is stored in the latches. As long as GL remains high no address changes will be recognized. Output enable controls, G1 and G2, control the state of the outputs independently of the select or latch-enable inputs. All of the outputs are high unless G1 is high and G2 is low. The HC137 is ideally suited for the implementation of glitchfree decoders in stored-address applications in bus oriented systems.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function and pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 20 ns
- Wide supply range: 2-6V
- Latched inputs for easy interfacing.
- Fanout of 10 LS-TTL loads.

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur. .
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " $N$ " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{H}}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{I}}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{I}_{\mathrm{N}}$, $\mathrm{I}_{\mathrm{CC}}$, and I I Z ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## Typical Application

TL/F/5310-3
6-Line to 64-Line Decoder with Input Address Storage

## MM54HC138/MM74HC138 3-to-8 Line Decoder

## General Description

This decoder utilizes microCMOS Technology, 3.5 micron silicon gate P -well CMOS, and is well suited to memory address decoding or data routing applications. The circuit features high noise immunity and low power consumption usually associated with CMOS circuitry, yet has speeds comparable to low power Schottky TTL logic.
The MM54HC138/MM74HC138 has 3 binary select inputs ( $\mathrm{A}, \mathrm{B}$, and C ). If the device is enabled these inputs determine which one of the eight normally high outputs will go low. Two active low and one active high enables (G1, G2A and $\overline{\mathrm{G} 2 \mathrm{~B}}$ ) are provided to ease the cascading of decoders.

The decoder's outputs can drive 10 low power Schottky TTL equivalent loads, and are functionally and pin equivalent to the 54LS138/74LS138. All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 20 ns
- Wide power supply range: $2 \mathrm{~V}-6 \mathrm{~V}$
a Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads

| Icc | Maximum Quiescent Supply Current | $\begin{aligned} & V_{\text {IN }}=V_{C C} \text { or } G N D \\ & I_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages $\left(\mathrm{V}_{\mathrm{OH}}\right.$, and $\left.\mathrm{V}_{\mathrm{OL}}\right)$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{I}}$ and $\mathrm{V}_{\mathbb{I}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{H}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN , $\mathrm{I}_{\mathrm{CC}}$, and $\mathrm{l}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC139/MM74HC139 Dual 2-To-4 Line Decoder

## General Description

This decoder utilizes microCMOS Technology, 3.5 micron silicon gate P -well CMOS, and is well suited to memory address decoding or data routing applications. It possesses the high noise immunity and low power consumption usually associated with CMOS circuitry, yet has speeds comparable to low power Schottky TTL logic.
The MM54HC139/MM74HC139 contain two independent one-of-four decoders each with a single active low enable input (G1, or G2). Data on the select inputs (A1, and B1 or A2, and B2) cause one of the four normally high outputs to go low.
The decoder's outputs can drive 10 low power Schottky TTL equivalent loads, and are functionally as well as pin equiva-
lent to the 54LS139/74LS139. All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delays -

Select to outputs (4 delays): 18 ns
Select to output ( 5 delays): 28 ns
Enable to output: 20 ns

- Low power: $40 \mu \mathrm{~W}$ quiescent supply power
- Fanout of 10 LS-TTL devices
- Input current maximum $1 \mu \mathrm{~A}$, typical 10 pA

## Truth Table

| Inputs |  |  |  |  |  |  |  |  | Outputs |  |  |  |

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC147/MM74HC147 10-to-4 Line Priority Encoder

## General Description

This high speed 10-to-4 Line Priority Encoder utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS. It possesses the high noise immunity and low power consumption of standard CMOS integrated circuits. This device is fully buffered, giving it a fanout of 10 LS-TTL loads.
The MM54HC147/MM74HC147 features priority encoding of the inputs to ensure that only the highest order data line is encoded. Nine input lines are encoded to a four line BCD output. The implied decimal zero condition requires no input condition as zero is encoded when all nine data lines are at a high logic level. All data inputs and outputs are active at the low logic level.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

■ Low quiescent power consumption: $40 \mu \mathrm{~W}$ maximum at $25^{\circ} \mathrm{C}$
n High speed: 31 ns propagation delay (typical)
$\square$ Very low input current: $10^{-5} \mu \mathrm{~A}$ typical

- Wide supply range: 2 V to 6 V

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " $N$ " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " $J$ " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{VOH}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{I H}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{I}}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{I}_{\mathrm{N}}$, lcc, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC149/MM74HC149 8 Line to 8 Line Priority Encoder

## General Description

This priority encoder utilizes microCMOS Technology, 3.5 micron' silicon gate P-well CMOS. It has the high noise immunity and low power consumption typical of CMOS circuits, as well as the speeds and output drive similar to LS-TTL.
This priority encoder accepts 8 input request lines, $\overline{\mathrm{RI} 7}-\overline{\mathrm{RIO}}$, and outputs 8 lines, $\overline{\mathrm{RO}}-\overline{\mathrm{ROO}}$. It is the logical combination of a '148 8-3 line priority encoder driving a '138 3-8 line decoder. Only one request output can be low at a time. The output that is low is dependent on the highest priority request that is low. The order of priority is RI7 highest and RIO lowest. Also provided is and enable input, $\overline{R Q E}$, which when high forces all outputs high. A request output is also provided, RQP, which goes low when any $\overline{R Q P}$ is active.
All inputs to this device are protected from damage due to electrostatic discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and Ground.

## Features

- Propagation delay: 15 ns typical
- Wide power supply range: 2-6V
- Low quiescent current: $80 \mu \mathrm{~A}$ max ( 74 HC series)
- Wide input noise immunity

Simplified Logic Diagram

## National Semiconductor MM54HC151/MM74HC151 8-Channel Digital Multiplexer

## General Description

This high speed DIGITAL MULTIPLEXER utilizes microCMOS Technology, 3.5 micron silicon gate $P$-well CMOS. Along with the high noise immunity and low power dissipation of standard CMOS integrated circuits, it possesses the ability to drive 10 LS-TTL loads. The MM54HC151/ MM74HC151 selects one of the 8 data sources, depending on the address presented on the A, B, and C inputs. It features both true (Y) and complement (W) outputs. The STROBE input must be at a low logic level to enable this multiplexer. A high logic level at the STROBE forces the W output high and the $Y$ output low.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family.

Dual-In-Line

MM54HC151/MM74HC151 54HC151 (J) $\quad 74 \mathrm{HC151}$ (J,N)

All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay data select to output Y: 26 ns
- Wide operating supply voltage range: 2-6V

■ Low input current: $<1 \mu \mathrm{~A}$ maximum

- Low quiescent supply current: $80 \mu \mathrm{~A}$ maximum ( 74 HC )
- High output drive current: 4 mA minimum

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{VOH}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. Icc, and lozl occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## AC Electrical Characteristics

$V_{C C}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$

| Symbol | Parameter | Conditions | Typ | Guaranteed LImit | Units |
| :---: | :---: | :---: | :---: | :---: | :---: |
| ${ }^{\text {tPHL. }}$ t PLH | Maximum Propagation Delay A, B or C to Y |  | 26 | 35 | ns |
| .$_{\text {tPHL, }}$ tPLH | Maximum Propagation Delay A, B or C to W |  | 27 | 35 | ns |

| $\mathrm{t}_{\text {PHL }}$ t PLH | Maximum Propagation Delay Strobe to $Y$ |  | 17 | 23 | ns |
| $\mathrm{t}_{\text {PHL }}$, $\mathrm{P}_{\text {PLH }}$ | Maximum Propagation Delay Strobe to W |  | 16 | 21 | ns |

AC Electrical Characteristics $\mathrm{C}_{\mathrm{L}}=50 \mathrm{pF}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{t}}=6$ ns (unless otherwise specified)

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+l_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+l_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC153/MM74HC153 Dual 4-Input Multiplexer

## General Description

This 4-to-1 line multiplex́er utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS. It has the low power consumption and high noise immunity of standard CMOS integrated circuits. This device is fully buffered, allowing it to drive 10 LS-TTL loads. Information on the data inputs of each multiplexer is selected by the address on the A and B inputs, and is presented on the $Y$ outputs. Each multiplexer possesses a strobe input which enables it when taken to a low logic level. When a high logic level is applied to a strobe input, the output of its associated multiplexer is taken low.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 24 ns
- Wide power supply range: 2V-6V
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum

■ Fanout of 10 LS-TTL loads

| IIN | Maximum Input Current | $\mathrm{V}_{\text {IN }}=\mathrm{V}_{\text {CC }}$ or GND | 6.0 V |  | $\pm 0.1$ | $\pm 1.0$ | $\pm 1.0$ | $\mu \mathrm{A}$ |
| ICC | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & I_{\text {OUT }}=0 \mu \mathrm{~A} \\ & \hline \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J" package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{I}_{\mathrm{N}}$, $\mathrm{I}_{\mathrm{Cc}}$, and $\mathrm{I}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

AC Electrical Characteristics $\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$

| Symbol | Parameter | Conditions | Typ | Guaranteed Limit | Units |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $t_{\text {PHL, }} \mathrm{t}_{\text {PLH }}$ | Maximum Propagation Delay, Select A or B to Y |  | 26 | 30 | ns |
| $\mathrm{tPHL}^{\text {P }}$ tPLH | Maximum Propagation Delay, Any Data to $Y$ |  | 20 | 23 | ns |
| tPHL, tPLH | Maximum Propagation Delay, Strobe to $Y$ |  | 8 | 15 | ns |

AC Electrical Characteristics $\mathrm{C}_{\mathrm{L}}=50 \mathrm{pF}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$ (unless otherwise specified)

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+l_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+I_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## Logic Diagram

## MM54HC154／MM74HC154 4－to－16 Line Decoder

## General Description

This decoder utilizes microCMOS Technology， 3.5 micron silicon gate P－well CMOS，and is well suited to memory ad－ dress decoding or data routing applications．It possesses high noise immunity，and low power consumption of CMOS with speeds similar to low power Schottky TTL circuits．
The MM54HC154／MM74HC154 have 4 binary select inputs （ $A, B, C$ ，and $D$ ）．If the device is enabled these inputs deter－ mine which one of the 16 normally high outputs will go low． Two active low enablès（ $\overline{\mathrm{G} 1}$ and $\overline{\mathrm{G} 2}$ ）are provided to ease cascading of decoders with little or no external logic．

Each output can drive 10 low power Schottky TTL equiva－ lent loads，and is functionally and pin equivalent to the $54 \mathrm{LS} 154 / 74 \mathrm{LS} 154$ ．All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground．

## Features

－Typical propagation delay： 21 ns
－Power supply quiescent current： $80 \mu \mathrm{~A}$（ 74 HC ）
© Wide power supply voltage range：2－6V
－Low input current： $1 \mu \mathrm{~A}$ maximum

TL/F/5122-2

National
Semiconductor

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 14 ns data to any output
- Wide power supply range: 2-6V
- Low power supply quiescent current: $80 \mu \mathrm{~A}$ maximum (74HC series)
m Fan-out of 10 LS-TTL loads
- Low input current: $1 \mu \mathrm{~A}$ maximum

These high speed QUAD 2-to-1 LINE DATA SELECTOR/ MULTIPLEXERS utilize microCMOS Technology, 3.5 micron
silicon gate P-well CMOS. They possess the high noise imsilicon gate P-well CMOS. They possess the high noise immunity and low power consumption of standard CMOS intemunity and low power consumption of standard CMOS inteloads.
These devices each consist of four 2-input digital multiplexers with common select and STROBE inputs. On the MM54HC157/MM74HC157, when the STROBE input is at logical " 0 " the four outputs assume the values as selected from the inputs. When the STROBE input is at a logical " 1 " the outputs assume logical " 0 ". The MM54HC158/ MM74HC158 operates in the same manner, except that its outputs are inverted. Select decoding is done internally resulting in a single select input only. If enabled, the select input determines whether the $A$ or $B$ inputs get routed to their corresponding $Y$ outputs.

# Synchronous Decade Counter with Asynchronous Clear MM54HC161/MM74HC161 Synchronous Binary Counter with Asynchronous Clear MM54HC162/MM74HC162 Synchronous Decade Counter with Synchronous Clear MM54HC163/MM74HC163 <br> <br> Synchronous Binary Counter with Synchronous Clear 

 <br> <br> Synchronous Binary Counter with Synchronous Clear}

## General Description

The MM54HC160/MM74HC160, MM54HC161/ MM74HC161, MM54HC162/MM74HC162, and MM54HC163/MM74HC163 synchronous presettable counters utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS, and internal look-ahead carry logic for use in high speed counting applications. They offer the high noise immunity and low power consumption inherent to CMOS with speeds similar to low power Schottky TTL. The 'HC160 and the 'HC162 are 4 bit decade counters, and the 'HC161 and the 'HC163 are 4 bit binary counters. All flip-flops are clocked simultaneously on the low to high to transition (positive edge) of the CLOCK input waveform.
These counters may be preset using the LOAD input. Presetting of all four flip-flops is synchronous to the rising edge of CLOCK. When LOAD is held low counting is disabled and the data on the $A, B, C$, and $D$ inputs is loaded into the counter on the rising edge of CLOCK. If the load input is taken high before the positive edge of CLOCK the count operation will be unaffected.
All of these counters may be cleared by utilizing the CLEAR input. The clear function on the MM54HC162/MM74HC162 and MM54HC163/MM74HC163 counters are synchronous to the clock. That is, the counters are cleared on the positive edge of CLOCK while the clear input is held low.

The MM54HC160/MM74HC160 and MM54HC161/ MM74HC161 counters are cleared asynchronously. When the CLEAR is taken low the counter is cleared immediately regardless of the CLOCK.
Two active high enable inputs (ENP and ENT) and a RIP. PLE CARRY (RC) output are provided to enable easy cascading of counters. Both ENABLE inputs must be high to count. The ENT input also enables the RC output. When enabled, the RC outputs a positive pulse when the counter overflows. This pulse is approximately equal in duration to the high level portion of the $Q_{A}$ output. The RC output is fed to successive cascaded stages to facilitate easy implementation of N -bit counters.
All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical operating frequency: 40 MHz
- Typical propagation delay; clock to $\mathrm{Q}: 18 \mathrm{~ns}$
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Wide power supply range: 2-6V

| lcc | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & I_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{O}} \mathrm{J}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN, Icc. and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC164/MM74HC164 <br> 8-Bit Serial-in/Parallel-out Shift Register

## General Description

The MM54HC164/MM74HC164 utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS. It has the high noise immunity and low consumption of standard CMOS integrated circuits. It also offers speeds comparable to low power Schottky devices.
This 8-BIT SHIFT REGISTER has gated serial inputs and CLEAR. Each register bit is a D-type master/slave flip flop. Inputs A \& B permit complete control over the incoming data. A low at either or both inputs inhibits entry of new data and resets the first flip flop to the low level at the next clock pulse. A high level on one input enables the other input which will then determine the state of the first flip flop. Data at the serial inputs may be changed while the clock is high or low, but only information meeting the setup and hold time requirements will be entered. Data is serially shifted in and out of the 8-BIT REGISTER during the positive going transition of the clock pulse. Clear is independent of the clock and accomplished by a low level at the CLEAR input.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical operating frequency: 50 MHz
- Typical propagation delay: 19 ns (Clock to Q )
- Wide operating supply voltage range: 2-6V
- Low input current: <1 $\mu \mathrm{A}$
- Low quiescent supply current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Fanout of 10 LS-TTL loads

## Connection Diagram

TL/F/5315-1

## Truth Table

| Inputs |  |  |  |  | Outputs |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Clear | Clock | $\mathbf{A}$ | $\mathbf{B}$ | $\mathbf{Q}_{\mathbf{A}}$ | $\mathbf{Q}_{\mathbf{B}}$ | $\ldots$ | $\mathbf{Q}_{\mathrm{H}}$ |  |
| L | X | X | X | L | L |  | L |  |
| H | L | X | X | $\mathrm{Q}_{\mathrm{AO}}$ | $\mathrm{Q}_{\mathrm{BO}}$ | $\cdot$ | $\mathrm{Q}_{\mathrm{HO}}$ |  |
| H | $\uparrow$ | H | H | H | $\mathrm{Q}_{\mathrm{An}}$ |  | $\mathrm{Q}_{\mathrm{Gn}}$ |  |
| H | $\uparrow$ | L | X | L | $\mathrm{Q}_{\mathrm{An}}$ |  | $\mathrm{Q}_{\mathrm{Gn}}$ |  |
| H | $\uparrow$ | X | L | L | $\mathrm{Q}_{\mathrm{An}}$ |  | $\mathrm{Q}_{\mathrm{Gn}}$ |  |

$\mathrm{H}=$ High Level (steady state), $\mathrm{L}=$ Low Level (steady state)
$X=$ Irrelevant (any input, including transitions)
$\uparrow=$ Transition from low to high level.
$Q_{A O}, Q_{B O}, Q_{H O}=$ the level of $Q_{A}, Q_{B}$, or $Q_{H}$, respectively, before the indicated steady state input conditions were established.
$Q_{\mathrm{A} n}, \mathrm{Q}_{\mathrm{Gn}}=$ The level of $\mathrm{Q}_{\mathrm{A}}$ or $\mathrm{Q}_{\mathrm{G}}$ before the most recent $\uparrow$ transition of the clock; indicated a one-bit shift.

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+l_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C}{ }^{i+I_{C C} .}$
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC165/MM74HC165 <br> Parallel-in/Serial-out 8-Bit Shift Register

## General Description

The MM54HC165/MM74HC165 high speed PARALLEL-IN/ SERIAL-OUT SHIFT REGISTER utilizes microCMOS Technology, 3.5 micron silicon gate P -well CMOS. It has the low power consumption and high noise immunity of standard CMOS integrated circuits, along with the ability to drive 10 LS-TTL loads.
This 8-bit serial shift register shifts data from $Q_{A}$ to $Q_{H}$ when clocked. Parallel inputs to each stage are enabled by a low level at the SHIFT/LOAD input. Also included is a gated CLOCK input and a complementary output from the eighth bit.

Clocking is accomplished through a 2 -input NOR gate permitting one input to be used as a CLOCK INHIBIT function. Holding either of the CLOCK inputs high inhibits clocking, and holding either CLOCK input low with the SHIFT/LOAD input high enables the other CLOCK input. Data transfer occurs on the positive going edge of the clock. Parallel load-
ing is inhibited as long as the SHIFT/LOAD input is high. When taken low, data at the parallel inputs is loaded directly into the register independent of the state of the clock.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 20 ns (Clock to Q )
- Wide operating supply voltage range: 2-6V
- Low input current: $<1 \mu \mathrm{~A}$
- Low quiescent supply current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Fanout of 10 LS-TTL loads

## Function Table

| Inputs |  |  |  |  | Internal Outputs | $\begin{gathered} \text { Output } \\ \mathbf{Q}_{\mathbf{H}} \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Shift/ Load | Clock | Clock | Serial | Parallel |  |  |
|  | Inhibit |  |  | A. . H | $\mathbf{Q}_{\mathbf{A}} \quad \mathbf{Q}_{B}$ |  |
| L | X | X | X | a. . h | a b | h |
| H | L | L | X | X | $Q_{A O} Q_{B O}$ | $Q_{\text {Ho }}$ |
| H | L | $\uparrow$ | H | X | $H Q_{A N}$ | $Q_{G N}$ |
| H | L | $\uparrow$ | L | X | $L Q_{A N}$ | $Q_{G N}$ |
| H | H | X | X | X | $\mathrm{Q}_{\mathrm{AO}} \mathrm{Q}_{\mathrm{BO}}$ | Q ${ }_{\text {Ho }}$ |

$H=$ High Level (steady state), $L=$ Low Level (steady state) $X=$ Irrelevant (any input, including transitions)
$\uparrow=$ Transition from low to high level
$\mathrm{Q}_{\mathrm{AO}}, \mathrm{Q}_{\mathrm{B} 0}, \mathrm{Q}_{\mathrm{H} 0}=$ The level of $\mathrm{Q}_{\mathrm{A}}, \mathrm{Q}_{\mathrm{B}}$, or $\mathrm{Q}_{\mathrm{H}}$, respectively, before the indicated steady-state input conditions were established.
$Q_{A N}, Q_{G N}=$ The level of $Q_{A}$ or $Q_{G}$ before the most recent $\uparrow$ transition of the clock; indicates a one-bit shift.

## Operating Conditions

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+l_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+I_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

Block Diagram

## MM54HC166/MM74HC166 8-Bit Serial or Parallel Input/Serial Output Shift Register with Reset

## General Description

These shift registers utilize microCMOS technology, 3.5 micron silicon gate P-well CMOS. The MM54HC166/ MM74HC166 are 8-bit shift registers with an output from the last stage. Data may be loaded into the register in either parallel or serial form.
When the shift/load input is low, the data is loaded asynchronously in parallel. When the shift/load input is high, the data is loaded serially on the rising edge of either Clock 1 or Clock 2 (see the Function Table). Reset is asynchronous and active low.
The 2-input NOR clock may be used either by combining two independent clock sources or by designating one of the clock inputs to act as a clock inhibit.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Wide power supply range: $2 \mathrm{~V}-6 \mathrm{~V}$

■ Low input current: $1 \mu \mathrm{~A}$ maximum

- Low quiescent current: $80 \mu \mathrm{~A}$ max ( 74 HC series)
- Fanout of 10 LS.TTL loads

| Icc | Maximum Quiescent Supply Current | $\begin{aligned} & \mathrm{V}_{\text {IN }}=\mathrm{V}_{\mathrm{CC}} \text { or GND } \\ & \mathrm{I}_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power dissipation temperature derating-plastlc " $N$ " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$, the worst-case output voltages ( $\mathrm{V}_{\mathrm{OH}}$ and $\mathrm{V}_{\mathrm{OU}}$ ) occur for HC at 4.5 V . Thus, the 4.5 V values should be used when designing with this supply. Worst-case $\mathrm{V}_{I H}$ and $V_{I L}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V , respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst-case leakage currents ( $I_{\mathrm{I}}, \mathrm{I}_{\mathrm{CC}}$, and IOZ ) occur for CMOS at the higher voltage, so the 6.0 V values should be used.

Logic Diagram

## MM54HC169/MM74HC169 4-Bit Up/Down Synchronous Binary Counter

## General Description

These counters are implemented using an advanced 3.0 micron silicon gate N -well microCMOS process to achieve high performance. These devices retain the low power and high noise immunity of CMOS logic, while offering the high speed operation and large output drive typically associated with bipolar circuits.

These counters are incremented or decremented on the rising edge of the CLK, clock, input if ENT and ENP are held low. The counters increment when the U/D input is at a logic " 1 ", and will decrement when U/D is low. The ENT input is fed forward to enable the carry output. RCO, ripple carry output, once enabled, will produce a low level pulse while the count is 0 (down count mode) or when the count is all 1s (up mode).
These counters are presettable, that is, they may be loaded
when LOAD is taken low and a rising edge appears on the CLK input.
The MM54HC169/MM74HC169 are functional, speed and pin equivalent to the equivalent LS-TTL circuit. Its inputs are protected from damage due to electrostatic discharge by diodes from $V_{C C}$ to ground.

## Features

- Wide power supply range: 2.0 V to 6.0 V
- High input noise immunity
- Wide operating frequency range: 30 MHz
- High output current drive: 6.0 mA min
- Low quiescent power consumption: $80 \mu \mathrm{~A}(74 \mathrm{HC})$

MM54HC173/MM74HC173 TRI-STATE ${ }^{\circledR}$ Quad D Flip-Flop

## General Description

The MM54HC173/MM74HC173 is a high speed TRI-STATE QUAD D TYPE FLIP-FLOP that utilizes microCMOS Technology, 3.5 micron silicon gate P -well CMOS. It possesses the low power consumption and high noise immunity of standard CMOS integrated circuits, and can operate at speeds comparable to the equivalent low power Schottky device. The outputs are buffered, allowing this circuit to drive 15 LS-TTL loads. The large output drive capability and TRI-STATE feature make this part ideally suited for interfacing with bus lines in a bus oriented system.
The four D TYPE FLIP-FLOPS operate synchronously from a common clock. The TRI-STATE outputs allow the device to be used in bus organized systems. The outputs are placed in the TRI-STATE mode when either of the two output disable pins are in the logic "1" level. The input disable allows the flip flops to remain in their present states without having to disrupt the clock. If either of the 2 input disables are taken to a logic " 1 " level, the Q outputs are fed back to
the inputs, forcing the flip flops to remain in the same state. Clearing is enabled by taking the CLEAR input to a logic " 1 " level. The data outputs change state on the positive going edge of the clock.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 18 ns
- Wide operating supply voltage range: 2-6V
- TRI-STATE outputs
- Low input current: <1 $\mu \mathrm{A}$ maximum
- Low quiescent supply current: $80 \mu \mathrm{~A}$ maximum $(74 \mathrm{HC})$
- High output drive current: 6 mA minimum

## Connection Diagram

## Truth Table

| Inputs |  |  |  |  | Output <br> Q |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Clear | Clock | Data Enable |  | Data D |  |
|  |  | G1 | G2 |  |  |
| H | X | X | X | X | L |
| L | L | X | X | X | $Q_{0}$ |
| L | $\uparrow$ | H | X | X | $Q_{0}$ |
| L | $\uparrow$ | X | H | X | $Q_{0}$ |
| L | $\uparrow$ | L | L | L | L |
| L | $\uparrow$ | 1 | L | H | H |

When either M or N (or both) is (are) high the output is disabled to the high-impedance state: however, sequential operation of the flip-flops is not affected.
$H=$ high level (steady state)
$L=$ low level (steady state)
$\uparrow=$ low-to-high level transition
$X=$ don't care (any input including transitions)
$Q_{0}=$ the level of $Q$ before the indicated steady state input conditions were established

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{I}}$ and $\mathrm{V}_{\mathbb{L}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (IIN, ${ }^{\mathrm{l} C \mathrm{C}}$, and $\mathrm{l}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC174/MM74HC174 Hex D Flip-Flops With Clear

## General Description

These edge triggered flip-flops utilize microCMOS Technology, 3.5 micron silicon gate P -well CMOS, to implement Dtype flip-flops. They possess high noise immunity, low power, and speeds comparable to low power Schottky TTL circuits. This device contains 6 master-slave flip-flops with a common clock and common clear. Data on the D input having the specified setup and hold times is transferred to the Q output on the low to high transition of the CLOCK input. The CLEAR input when low, sets all outputs to a low state.
Each output can drive 10 low power Schottky TTL equivalent loads. The MM54HC174/MM74HC174 is functionally as well as pin compatible to the 54LS174/74LS174. All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

## Features

Typical propagation delay: 16 ns
a Wide operating voltage range: 2-6V

- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ ( 74 HC series)
a Output drive: 10 LSTTL loads

## MM54HC175/MM74HC175 <br> Quad D-Type Flip-Flop With Clear

## General Description

This high speed D-TYPE FLIP-FLOP with complementary outputs utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS, to achieve the high noise immunity and low power consumption of standard CMOS integrated circuits, along with the ability to drive 10 LS-TTL loads.
Information at the $D$ inputs of the MM54HC175/ MM74HC175 is transferred to the $Q$ and $\bar{Q}$ outputs on the positive going edge of the clock pulse. Both true and complement outputs from each flip flop are externally available. All four flip flops are controlled by a common clock and a common CLEAR. Clearing is accomplished by a negative pulse at the CLEAR input. All four Q outputs are cleared to a logical " 0 " and all four $Q$ outputs to a logical "1."

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 15 ns
- Wide operating supply voltage range: 2-6V
- Low input current: <1 $\mu \mathrm{A}$ maximum
- Low quiescent supply current: $80 \mu \mathrm{~A}$ maximum ( 74 HC )
- High output drive current: 4 mA minimum ( 74 HC )

Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages $\left(\mathrm{V}_{\mathrm{OH}}\right.$, and $\mathrm{V}_{\mathrm{O}} \mathrm{J}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{1 \mathrm{H}}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (IN, ICC , and $\mathrm{I}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+I_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+I_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## Logic Diagram

TL/F/5319-2

## MM54HC181/MM74HC181

## Arithmetic Logic Units/Function Generators

## General Description

These arithmetic logic units (ALU)/function generators utilize microCMOS Technology, 3.5 micron silicon gate P -well CMOS. They possess the high noise immunity and low power consumption of standard CMOS integrated circuits, as well as the ability to drive 10 LS-TTL loads.
The MM54HC181/MM74HC181 are arithmetic logic unit (ALU)/function generators that have a complexity of 75 equivalent gates on a monolithic chip. These circuits perform 16 binary arithmetic operations on two 4-bit words as shown in Tables 1 and 2. These operations are selected by the four function-select lines (S0, S1, S2, S3) and include addition, subtraction, decrement, and straight transfer. When performing arithmetic manipulations, the internal carries must be enabled by applying a low-level voltage to the mode control input (M). A full carry look-ahead scheme is made available in these devices for fast, simultaneous carry generation by means of two cascade-outputs (pins 15 and 17) for the four bits in the package. When used in conjunction with the MM54HC182 or MM74HC182, full carry lookahead circuits, high-speed arithmetic operations can be performed. The method of cascading HC182 circuits with these ALU's to provide multi-level full carry look-ahead is illustrated under typical applications data for the MM54HC182/ MM74HC182.

If high speed is not of importance, a ripple-carry input ( $\mathrm{C}_{\mathrm{n}}$ ) and a ripple-carry output ( $\mathrm{C}_{\mathrm{n}}+4$ ) are available. However, the ripple-carry delay has also been minimized so that arithmetic manipulations for small word lengths can be performed without external circuitry.

## Features

- Full look-ahead for high-speed operations on long words
- Arithmetic operating modes:

Addition
Subtraction
Shift operand a one position magnitude comparison
Plus Twelve other arithmetic operations

- Logic function modes:

Exclusive-OR
Comparator
AND, NAND, OR, NOR
Plus ten other logic operations

- Wide operating voltage range: $2 \mathrm{~V}-6 \mathrm{~V}$
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum

| A = B | 14 | Comparator Outputs |
| P | 15 | Carry Propagate <br> Output |
| C $_{n}+4$ | 16 | Inv. Carry Output |
| G | 17 | Carry Generate <br> Output |
| VCC $_{\text {GND }}$ | 24 | 12 |
| Supply Voltage |  |  |

General Description (Continued)

These circuits will accommodate active-high or active-low data, if the pin designations are interpreted as shown below.
Subtraction is accomplished by 1 's complement addition where the 1 's complement of the subtrahend is generated internally. The resultant output is A-B-1, which requires an end-around or forced carry to produce A-B.
The 181 can also be utilized as a comparator. The $A=B$ output is internally decoded from the function outputs (FO, F1, F2, F3) so that when two words of equal magnitude are applied at the $A$ and $B$ inputs, it will assume a high level to indicate equality $(A=B)$. The ALU should be in the subtract mode with $\mathrm{C}_{\mathrm{n}}=\mathrm{H}$ when performing this comparison. The $\mathrm{A}=\mathrm{B}$ output is open-drain so that it can be wire-AND connected to give a comparison for more than four bits. The carry output $\left(C_{n}+4\right)$ can also be used to supply relative magnitude information. Again, the ALU should be placed in the subtract mode by placing the function select inputs S3, S2, S1, S0 at L, H, H, L, respectively.
These circuits have been designed to not only incorporate all of the designer's requirements for arithmetic operations,
but also to provide 16 possible functions of two Boolean variables without the use of external circuitry. These logic functions are selected by use of the four function-select inputs (S0, S1, S2, S3) with the mode-control inpu (M) at a high level to disable the internal carry. The 16 logic functions are detailed in Tables 1 and 2 and include exclusiveOR, NAND, AND, NOR, and OR functions.

## ALU SIGNAL DESIGNATIONS

The MM54HC181/MM74HC181 can be used with the signal designations of either Figure 1 or Figure 2.
The logic functions and arithmetic operations obtained with signal designations as in Figure 1 are given in Table 1; those obtained with the signal designations of Figure 2 are given in Table 2.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function, and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

| ICC | Maximum Quiescent Supply Current | $\begin{aligned} & \mathrm{V}_{\mathrm{IN}}=\mathrm{V}_{\mathrm{CC}} \text { or GND } \\ & \mathrm{I}_{\mathrm{OUT}}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramlc " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OU}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{I}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{H}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. $\mathrm{I}_{\mathrm{CC}}$, and $\mathrm{I}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## AC Electrical Characteristics

## MM54HC182／MM74HC182 <br> Look－Ahead Carry Generator

## General Description

The MM54HC182／MM74HC182 is a high speed LOOK－ AHEAD CARRY GENERATOR utilize microCMOS Technol－ ogy， 3.5 micron silicon gate P－well CMOS．It has the low power consumption and high noise immunity of standard CMOS integrated circuits，along with the ability to drive 10 LS－TTL loads．
These circuits are capable of anticipating a carry across four binary adders or groups of adders．They are cascadable to perform full look－ahead across n－bit adders．Carry，gener－ ate－carry，and propagate－carry functions are provided as shown in the pin designation table．
When used in conjunction with the HC181 arithmetic logic unit，these generators provide high－speed carry look－ahead capability for any word length．Each HC182 generates the look－ahead（anticipated carry）across a group of four ALU＇s and，in addition，other carry look－ahead circuits may be em－ ployed to anticipate carry across sections of four look－ ahead packages up to $n$－bits．The method of cascading cir－ cuits to perform multi－level look－ahead is illustrated under typical application data．

Carry input and output of the ALU＇s are in their true form， and the carry propagate（ P ）and carry generate（ G ）are in negated form；therefore，the carry functions（inputs，outputs， generate，and propagate）of the look－ahead generators are implemented in the compatible forms for direct connection to the ALU．Reinterpretations of carry functions as ex－ plained on the HC181 data sheet are also applicable to and compatible with the look－ahead generator．

## Features

－TTL pinout compatible
－Typical propagation delay： 18 ns（Clock to Q）
－Wide Operating Supply Voltage Range：2－6V
－Low Input Current：＜ $1 \mu \mathrm{~A}$
－Low Quiescent Supply Current： $80 \mu \mathrm{~A}$ maximum（ 74 HC Series）
a Fanout of 10 LS－TTL Loads

| ${ }^{\text {ICC }}$ | Maximum Quiescent Supply Current | $\begin{aligned} & V_{\text {IN }}=V_{C C} \text { or GND } \\ & \text { IOUT }=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " $N$ " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{1 H}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{1 H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (IIN, ${ }^{\prime} \mathrm{CC}$, and $\mathrm{l}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## AC Electrical Characteristics $\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$

# MM54HC190/MM74HC190 Synchronous Decade Up/Down Counters with Mode Control MM54HC191/MM74HC191 Synchronous Binary Up/Down Counters with Mode Control 

## General Description

These high speed synchronous counters utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS. They possess the high noise immunity and low power consumption of CMOS technology, along with the speeds of low power Schottky TTL.
These circuits are synchronous, reversible, up/down counters. The MM54HC191/MM74HC191 are 4-bit binary counters and the MM54HC190/MM74HC190 are BCD counters. Synchronous operation is provided by having all flip-flops clocked simultaneously, so that the outputs change simultaneously when so instructed by the steering logic. This mode of operation eliminates the output counting spikes normally associated with asynchronous (ripple clock) counters.
The outputs of the four master-slave flip-flops are triggered on a low-to-high level transition of the clock input, if the enable input is low. A high at the enable input inhibits counting. The direction of the count is determined by the level of the down/up input. When low, the counter counts up and when high, it counts down.
These counters are fully programmable; that is, the outputs may be preset to either level by placing a low on the load input and entering the desired data at the data inputs. The output will change independent of the level of the clock in-
put. This feature allows the counters to be used as modulo$N$ dividers by simply modifying the count length with the preset inputs.
Two outputs have been made available to perform the cascading function: ripple clock and maximum/minimum count. The latter output produces a high-level output pulse with a duration approximately equal to one complete cycle of the clock when the counter overflows or underflows. The ripple clock output produces a low-level output pulse equal in width to the low-level portion of the clock input when an overflow or underflow condition exists. The counters can be easily cascaded by feeding the ripple clock output to the enable input of the succeeding counter if parallel clocking is used, or to the clock input if parallel enabling is used. The maximum/minimum count output can be used to accomplish look-ahead for high-speed operation.

## Features

- Typical propagation delay

Clock to output: 24 ns

- Typical operating frequency: 50 MHz
- Wide power supply range: 2-6V
- Low quiescent supply current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum

Connection Diagram

| Load | Enable <br> G | Down/ <br> Up | Clock | Function |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J" package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $V_{O H}$, and $V_{O L}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $V_{I H}$ and $V_{I L}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (IIN, $\mathrm{I}_{\mathrm{CC}}$, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

AC Electrical Characteristics $T_{A}=25^{\circ} \mathrm{C}, \mathrm{V}_{\mathrm{CC}}=5.0 \mathrm{~V}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}, \mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}$ (unless otherwise specified)

## MM54HC192/MM74HC192 Synchronous Decade Up/Down Counters MM54HC193/MM74HC193 Synchronous Binary Up/Down Counters

## General Description

These high speed synchronous counters utilize microCMOS Technology, 3.5 micron silicon gate P -well CMOS, to achieve the high noise immunity and low power consumption of CMOS technology, along with the speeds of low power Schottky TTL. The MM54HC192/MM74HC192 is a decade counter, and the MM54HC193/MM74HC193 is a binary counter. Both counters have two separate clock inputs, an UP COUNT input and a DOWN COUNT input. All outputs of the flip-flops are simultaneously triggered on the low to high transition of either clock while the other input is held high. The direction of counting is determined by which input is clocked.
These counters may be preset by entering the desired data on the DATA A, DATA B, DATA C, and DATA D inputs. When the LOAD input is taken low the data is loaded independently of either clock input. This feature allows the counters to be used as divide-by-n counters by modifying the count length with the preset inputs.
In addition both counters can also be cleared. This is accomplished by inputting a high on the CLEAR input. All 4 internal stages are set to a low level independently of either COUNT input.

Both a BORROW and CARRY output are provided to enable cascading of both up and down counting functions. The BORROW output produces a negative going pulse when the counter underflows and the CARRY outputs a pulse when the counter overflows. The counters can be cascaded by connecting the CARRY and BORROW outputs of one device to the COUNT UP and COUNT DOWN inputs, respectively, of the next device.
All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

## Features

- Typical propagation delay,

Clock to output: 20 ns

- Typical operating frequency: 27 MHz
- Wide power supply range: 2-6V
- Low quiescent supply current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- 4 mA output drive

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " $N$ " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN , $\mathrm{l}_{\mathrm{Cc}}$, and $\mathrm{I}_{\mathrm{OZ}}$ occur for CMOS at the higher voltage and so the 6.0 V values should be used.

MM54HC192 Synchronous 4-Bit Up/Down Decade Counter

MM54HC193 Synchronous 4-Bit Up/Down Binary Counter

TL/F/5011-3
'HC192 Synchronous Decade Counters Typlcal Clear, Load, and Count Sequences

Sequences:
TL/F/5011-4
(1) Clear outputs to zero
(2) Load (preset) to BCD seven.
(3) Count up to eight, nine, carry, zero, one and two.
(4) Count down to one, zero, borrow, nine, eight, and seven.
'HC193 Synchronous Binary Counters Typical Clear, Load, and Count Sequences

Sequence:
TL/F/5011-5
(1) Clear outputs to zero.
(2) Load (preset) to binary thirteen
(3) Count up to fourteen, fifteen, carry, zero, one, and two.
(4) Count down to one, zero, borrow, fifteen, fourteen, and thirteen.

Note A: Clear overrides load data, and count inputs.
Note B: When counting up, count-down input must be high; when counting down, count-up input must be high. MM54HC194/MM74HC194

## 4-Bit Bidirectional Universal Shift Register

## General Description

This 4-bit high speed BIDIRECTIONAL SHIFT REGISTER utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS, to achieve the low power consumption and high noise immunity of standard CMOS integrated circuits, along with the ability to drive 10 LS-TTL loads. This device operates at speeds similar to the equivalent low power Schottky part.
This BIDIRECTIONAL SHIFT REGISTER is designed to incorporate virtually all of the features a system designer may want in a shift register. It features parallel inputs, parallel outputs, right shift and left shift serial inputs, operating mode control inputs, and a direct overriding clear line. The register has four distinct modes of operation: PARALLEL (broadside) LOAD; SHIFT RIGHT (in the direction $Q_{A}$ toward $Q_{D}$ ); SHIFT LEFT; INHIBIT CLOCK (do nothing).
Synchronous parallel loading is accomplished by applying the four bits of data and taking both mode control inputs, SO and S1, high. The data are loaded into their respective flip flops and appear at the outputs after the positive transition of the CLOCK input. During loading, serial data flow is inhibited. Shift right is accomplished synchronously with the rising edge of the clock pulse when S 0 is high and S 1 is low.

Serial data for this mode is entered at the SHIFT RIGHT data input. When S0 is low and S1 is high, data shifts left synchronously and new data is entered at the SHIFT LEFT serial input. Clocking of the flip flops is inhibited when both mode control inputs are low. The mode control inputs should be changed only when the CLOCK input is high.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

■ Typical operating frequency: 45 MHz

- Typical propagation delay: ns (Clock to Q)
- Wide operating supply voltage range: 2-6V
- Low input current: $1 \mu \mathrm{~A}$ maximum

■ Low quiescent supply current: $160 \mu \mathrm{~A}$ maximum ( 74 HC series)

- Fanout of 10 LS-TTL loads

Connection Diagram Dual-In-Line Package

## MM54HC195/MM74HC195 4-Bit Parallel Shift Register

## General Description

The MM54HC195/MM74HC195 is a high speed 4-bit SHIFT REGISTER utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS, to achieve the low power consumption and high noise immunity of standard CMOS integrated circuits, along with the ability to drive 10 LS-TTL loads at LS type speeds.
This shift register features parallel inputs, parallel outputs, J$\overline{\mathrm{K}}$ serial inputs, SHIFT/LOAD control input, and a direct overriding CLEAR. This shift register can operate in two modes: Parallel Load; Shift from $Q_{A}$ towards $Q_{D}$.
Parallel loading is accomplished by applying the four bits of data, and taking the SHIFT/LOAD control input low. The data is loaded into the associated flip flops and appears at the outputs after the positive transition of the clock input. During parallel loading, serial data flow is inhibited. Serial shitting occurs synchronously when the SHIFT/LOAD control input is high. Serial data for this mode is entered at the $J-K$ inputs. These inputs allow the first stage to perform as a $\mathrm{J}-\mathrm{K}$ or TOGGLE flip flop as shown in the truth table.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical operating frequency: 45 MHz
- Typical propagation delay: 16 ns (Clock to Q )
- Wide operating supply voltage range: 2-6V
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)

■ Fanout of 10 LS-TTL loads

Timing Diagram

## MM54HC221A/MM74HC221A Dual Non-Retriggerable Monostable Multivibrator

## General Description

The MM54/74HC221A high speed monostable multivibrators (one shots) utilize microCMOS Technology, 3.5 micron silicon gate P -well CMOS. Théy feature speeds comparable to low power Schottky TTL circuitry while retaining the low power and high noise immunity characteristic of CMOS circuits.
Each multivibrator features both a negative, $A$, and a positive, B, transition triggered input, either of which can be used as an inhibit input. Also included is a clear input that when taken low resets the one shot. The 'HC221A can be triggered on the positive transition of the clear while $A$ is held low and $B$ is held high.
The 'HC221A is a non-retriggerable, and therefore cannot be retriggered until the output pulse times out.
Pulse width stability over a wide range of temperature and supply is achieved using linear CMOS techniques. The output pulse equation is simply: $\mathrm{PW}=\left(\mathrm{R}_{\mathrm{EXT}}\right)\left(\mathrm{C}_{\mathrm{EXT}}\right)$; where PW
is in seconds, $R$ is in ohms, and $C$ is in farads. All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 40 ns
- Wide power supply range: 2V-6V
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( $\mathbf{7 4 \mathrm { HC }}$ series)
- Low input current: $1 \mu \mathrm{~A}$ maximum

■ Fanout of 10 LS-TTL loads

- Simple pulse width formula $T=$ RC
$\square$ Wide pulse range: 400 ns to $\infty$ (typ)
- Part to part variation: $\pm 5 \%$ (typ)
- Schmitt Trigger A \& B inputs enable infinite signal input rise or fall times

## Truth Table

| Inputs |  |  | Outputs |  |
| :---: | :---: | :---: | :---: | :---: |
| Clear | A | B | 0 | $\overline{\mathbf{a}}$ |
| L | X | X | L | H |
| X | H | X | L | H |
| X | X | L | L | H |
| H | L | $\uparrow$ | $\Omega$ | บ |
| H | $\downarrow$ | H | $\Omega$ | บ |
| $\uparrow$ | L | H | $\Omega$ | ㄴ |

$H=$ High Level
$L=$ Low Level

- $\uparrow=$ Transition from Low to High
$\downarrow=$ Transition from High to Low
$\Omega=$ One High Level Pulse
工 = One Low Level Pulse
X $=$ Irrelevant

Absolute Maximum Ratings (Notes 1 \& 2)
Supply Voltage (VCc)
DC Input Voltage ( $\mathrm{V}_{\text {IN }}$ )
DC Output Voltage (VOUT)
Clamp Diode Current (IIK, IOK)
DC Output Current, per pin (lout)
DC $V_{\text {CC }}$ or GND Current, per pin (ICC)
Storage Temperature Range ( $\mathrm{T}_{\mathrm{STG}}$ )
Power Dissipation ( $\mathrm{P}_{\mathrm{D}}$ ) (Note 3)
Lead Temperature (TL) (Soldering 10 seconds) $260^{\circ} \mathrm{C}$
-0.5 V to +7.0 V
-1.5 V to $\mathrm{V}_{\mathrm{CC}}+1.5 \mathrm{~V}$
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$\pm 20 \mathrm{~mA}$
$\pm 25 \mathrm{~mA}$
$\pm 50 \mathrm{~mA}$
$-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ 500 mW

Operating Conditions

| Min | Max | Units |

| In | Maximum Input Current (All other pins) | $\mathrm{V}_{1 \mathrm{~N}}=\mathrm{V}_{\text {CC }}$ or GND | 6.0 V |  | $\pm 0.1$ | $\pm 1.0$ | $\pm 1.0$ | $\mu \mathrm{A}$ |
| Icc | Maximum Quiescent Supply Current (Standby) | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & I_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |
| Icc | Maximum Active Supply Current (per monostable | $\begin{aligned} & \mathrm{V}_{I N}=\mathrm{V}_{\mathrm{CC}} \text { or } \mathrm{GND} \\ & \mathrm{R} / \mathrm{C}_{\mathrm{EXT}}=0.5 \mathrm{~V}_{\mathrm{CC}} \end{aligned}$ | $\begin{aligned} & 2.0 \mathrm{~V} \\ & 4.5 \mathrm{~V} \\ & 6.0 \mathrm{~V} \end{aligned}$ | $\begin{gathered} 36 \\ 0.33 \\ 0.7 \end{gathered}$ | $\begin{aligned} & 80 \\ & 1.0 \\ & 2.0 \end{aligned}$ | $\begin{aligned} & 110 \\ & 1.3 \\ & 2.6 \end{aligned}$ | $\begin{aligned} & 130 \\ & 1.6 \\ & 3.2 \end{aligned}$ | $\mu \mathrm{A}$ <br> $m A$ <br> mA |

Note 1: Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst-case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst-case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst-case leakage current ( $I_{\mathrm{N}}, \mathrm{I}_{\mathrm{CC}}$, and $\mathrm{I}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

AC Electrical Characteristics $\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$

## Theory of Operation

## TRIGGER OPERATION

As shown in Figure 1 and the logic diagram before an input trigger occurs, the monostable is in the quiescent state with the Q output low, and the timing capacitor $\mathrm{C}_{\text {EXT }}$ completely charged to $V_{C C}$. When the trigger input $A$ goes from $V_{C C}$ to GND (while inputs B and clear are held to $\mathrm{V}_{\mathrm{CC}}$ ) a valid trig: ger is recognized, which turns on comparator C 1 and N Channel transistor N1©. At the same time the output latch is set. With transistor N1 on, the capacitor CEXT rapidly discharges toward GND until VREF1 is reached. At this point the output of comparator C 1 changes state and transistor N 1 turns off. Comparator C 1 then turns off while at the same time comparator C2 turns on. With transistor N1 off, the capacitor $C_{E X T}$ begins to charge through the timing resistor, $\mathrm{R}_{\mathrm{EXT}}$, toward $\mathrm{V}_{\mathrm{CC}}$. When the voltage across $\mathrm{C}_{\text {EXT }}$ equals $V_{\text {REF2 }}$, comparator C2 changes state causing the output latch to reset ( Q goes low) while at the same time disabling comparator C 2 . This ends the timing cycle with the monostable in the quiescent state, waiting for the next trigger.
A valid trigger is also recognized when trigger input $B$ goes from GND to $V_{C C}$ (while input $A$ is at GND and input clear is at $\mathrm{V}_{\mathrm{CC}}{ }^{(3}$. The 'HC221 can also be triggered when clear goes from GND to $V_{C C}$ (while $A$ is at Gnd and $B$ is at $\mathrm{V}_{\mathrm{CC}}{ }^{(6 .)}$
It should be noted that in the quiescent state $\mathrm{C}_{\mathrm{EXT}}$ is fully charged to $V_{C C}$ causing the current through resistor $R_{E X T}$
to be zero. Both comparators are "off" with the total device current due only to reverse junction leakages. An added feature of the 'HC221 is that the output latch is set via the input trigger without regard to the capacitor voltage. Thus, propagation delay from trigger to $Q$ is independent of the value of CEXT, R $\mathrm{R}_{\mathrm{EXT}}$, or the duty cycle of the input waveform.
The 'HC221 is non-retriggerable and will ignore input transitions on A and B until it has timed out (3) and (9).

## RESET OPERATION

These one shots may be reset during the generation of the output pulse. In the reset mode of operation, an input pulse on clear sets the reset latch and causes the capacitor to be fast charged to $\mathrm{V}_{\mathrm{CC}}$ by turning on transistor Q1 (3). When the voltage on the capacitor reaches $\mathrm{V}_{\text {REF2 }}$, the reset latch will clear and then be ready to accept another pulse. If the clear input is held low, any trigger inputs that occur will be inhibited and the $\mathbf{Q}$ and $\bar{Q}$ outputs of the output latch will not change. Since the $Q$ output is reset when an input low level is detected on the Clear input, the output pulse $\mathbf{T}$ can be made significantly shorter than the minimum pulse width specification.

Note: R and C are not subjected to temperature. The C is polypropolyne.

## MM54HC237/MM74HC237

## 3-to-8 Line Decoder With Address Latches

## General Description

These devices utilize microCMOS Technology, 3.5 micron silicon gate P -well CMOS, to implement a three-to-eight line decoder with latches on the three address inputs. When GL goes from low to high, the address present at the select inputs ( $A, B$ and $C$ ) is stored in the latches. As long as $\overline{G L}$ remains high no address changes will be recognized. Output enable controls, G1 and G2, control the state of the outputs independently of the select or latch-enable inputs. All of the outputs are low unless G1 is high and G2 is low. The 'HC237 is ideally suited for the implementation of glitchfree decoders in stored-address applications in bus oriented systems.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function and pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 20 ns
- Wide supply range: 2-6V
- Latched inputs for easy interfacing.
- Fanout of 10 LS-TTL loads.

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. $I_{\mathrm{CC}}$, and $\mathrm{l}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

AC Electrical Characteristics $\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+I_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+l_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

Typical Application

## MM54HC240/MM74HC240 <br> Inverting Octal TRI-STATE ${ }^{\circledR}$ Buffer <br> MM54HC241/MM74HC241 Octal TRI-STATE Buffer

## General Description

These TRI-STATE buffers utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS. They possess high drive current outputs which enable high speed operation even when driving large bus capacitances. These circuits achieve speeds comparable to low power Schottky devices, while retaining the advantage of CMOS circuitry, i.e., high noise immunity, and low power consumption. Each have a fanout of 15 LS-TTL equivalent inputs.
The MM54HC240/MM74HC240 is an inverting buffer and has two active low enables ( $1 \overline{\mathrm{G}}$ and $2 \overline{\mathrm{G}}$ ). Each enable independently controls 4 buffers. MM54HC241/MM74HC241 is a non-inverting buffer that has one active low enable and one active high enable, each again controlling 4 buffers. Neither device has Schmitt trigger inputs.
All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 12 ns
- TRI-STATE outputs for connection to system buses
- Wide power supply range: 2-6V
- Low quiescent supply current: $80 \mu \mathrm{~A}$ ( 74 series)
- Output current: 6 mA

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J" package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages $\left(\mathrm{V}_{\mathrm{OH}}\right.$, and $\mathrm{V}_{\mathrm{OL}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $l_{\mathrm{IN}}$, icc, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC242/MM74HC242 Inverting Quad TRI-STATE® Transceiver MM54HC243/MM74HC243 Quad TRI-STATE Transceiver

## General Description

These TRI-STATE bi-directional inverting and non-inverting buffers utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS, and are intended for two-way asynchronous communication between data buses. They have high drive current outputs which enable high speed operation when driving large bus capacitances. These circuits possess the low power dissipation and high noise immunity associated with CMOS circuits, but speeds comparable to low power Schottky TTL circuits. They can also drive 15 LS-TTL loads.
The MM54HC242/MM74HC242 is a non-inverting buffer and the MM54HC243/MM74HC243 is an inverting buffer. Each device has one active high enable (GBA), and one active low enable (GAB). GBA enables the A outputs and

GAB enables the B outputs. This device does not have Schmitt trigger inputs.
All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

Typical propagation delay: 12 ns

- TRI-STATE outputs
- Two way asynchronous communication
- High output current: $6 \mathrm{~mA}(74 \mathrm{HC})$
- Wide power supply range: 2-6V
- Low quiescent supply current: $80 \mu \mathrm{~A}(74 \mathrm{HC})$

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( VOH, and VOJ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{I}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{I}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (IN. $\mathrm{l}_{\mathrm{CC}}$, and $\mathrm{l}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.
$V_{C C}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$

## MM54HC244／MM74HC244 Octal TRI－STATE® Buffer

## General Description

These TRI－STATE buffers utilize microCMOS Technology， 3.5 micron silicon gate P－well CMOS，and are general pur－ pose high speed non－inverting buffers．They possess high drive current outputs which enable high speed operation even when driving large bus capacitances．These circuits achieve speeds comparable to low power Schottky devices， while retaining the advantage of CMOS circuitry，i．e．，high noise immunity，and low power consumption．All three de－ vices have a fanout of 15 LS－TTL equivalent inputs．
The MM54HC244／MM74HC244 is a non－inverting buffer and has two active low enables（1G and 2G）．Each enable independently controls 4 buffers．This device does not have Schmitt trigger inputs．
All inputs are protected from damage due to static dis－ charge by diodes to $V_{C C}$ and ground．

## Features

－Typical propagation delay： 12 ns
－TRI－STATE outputs for connection to system buses
－Wide power supply range：2－6V
－Low quiescent supply current： $80 \mu \mathrm{~A}$（ 74 series）
■ Output current： 6 mA

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OU}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. ${ }^{\prime} \mathrm{CC}$, and $\mathrm{l}_{\mathrm{OL}}$ occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC245/MM74HC245 Octal TRI-STATE ${ }^{\circledR}$ Transceiver

## General Description

These TRI-STATE bi-directional buffers utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS, and are intended for two-way asynchronous communication between data buses. They have high drive current outputs which enable high speed operation even when driving large bus capacitances. This circuit possesses the low power consumption and high noise immunity usually associated with CMOS circuitry, yet have speeds comparable to low power Schottky TTL circuits.
This device has an active low enable input $\bar{G}$ and a direction control input, DIR. When DIR is high, data flows from the A inputs to the B outputs. When DIR is low, data flows from the $B$ inputs to the A outputs. The MM54HC245/ MM74HC245 transfers true data from one bus to the other.

This device can drive up to 15 LS-TTL Loads, and does not have Schmitt trigger inputs. All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

■ Typical propagation delay: 14 ns
■ Wide power supply range: 2-6V

- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC )
- TRI-STATE outputs for connection to bus oriented systems
- High output drive: 6 mA (minimum)
- Same as the '645

## Connection Diagram

Note 1: Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{VOL}_{\mathrm{O}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{1 H}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $l_{I N}$, $\mathrm{I}_{\mathrm{CC}}$, and $\mathrm{l}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+I_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+l_{\text {CC }}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

Logic Diagram

MM54HC251/MM74HC251 8-Channel TRI-STATE® Multiplexer

## General Description

This 8-CHANNEL DIGITAL MULTIPLEXER with TRI-STATE outputs utilizes microCMOS Technology, 3.5 micron silicon gate $P$-well CMOS. Along with the high noise immunity and low power consumption of standard CMOS integrated circuits, it possesses the ability to drive 10 LS-TTL loads. The large output drive capability and TRI-STATE feature make this part ideally suited for interfacing with bus lines in a bus oriented system.
This multiplexer features both true $(\mathrm{Y})$ and complement (W) outputs as well as a STROBE input. The STROBE must be at a low logic level to enable this device. When the STROBE input is high, both outputs are in the high impedance state. When enabled, address information on the data select inputs determines which data input is routed to the Y and W
outputs. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function, as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- Typical propagation delay Data Select to $\mathrm{Y}: 26 \mathrm{~ns}$
- Wide supply range: 2-6V
- Low power supply quiescent current: $80 \mu \mathrm{~A}$ maximum (74HC)
- TRI-STATE outputs for interface to bus oriented systems

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC253/MM74HC253

## Dual 4-Channel TRI-STATE ${ }^{\circledR}$

Multiplexer

## General Description

The MM54HC253/MM74HC253 utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS, to achieve the low power consumption and high noise immunity of standard CMOS integrated circuits, along with the capability to drive 10 LS-TTL loads. The large output drive and TRISTATE features of this device make it ideally suited for interfacing with bus lines in bus organized systems. When the output control input is taken high, the multiplexer outputs are sent into a high impedance state.
When the output control is held low, the associated multiplexer chooses the correct output channel for the given input signals determined by the select $A$ and $B$ inputs.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 24 ns
- Wide power supply range: $2 \mathrm{~V}-6 \mathrm{~V}$

■ Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)

- Low input current: $1 \mu \mathrm{~A}$ maximum
m Fanout of 10 LS-TTL loads

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. Icc, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

'HC253

## MM54HC257/MM74HC257 Quad 2-Channel TRI-STATE® Multiplexer

## General Description

This QUAD 2-TO-1 LINE DATA SELECTOR/MULTIPLEXER utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS. Along with the high noise immunity and low power dissipation of standard CMOS integrated circuits, it possesses the ability to drive LS-TTL loads. The large output drive capability coupled with the TRI-STATE feature make this device ideal for interfacing with bus lines in a bus organized system. When the OUTPUT CONTROL input line is taken high, the outputs of all four multiplexers are sent into a high impedance state. When the OUTPUT CONTROL line is low, the SELECT input chooses whether the A or B input is used.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function, and pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 12 ns
- Wide power supply range: $2 \mathrm{~V}-6 \mathrm{~V}$
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)
- TRI-STATE outputs for connection to system buses.

## Connection and Logic Diagrams

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages $\left(\mathrm{V}_{\mathrm{OH}}\right.$, and $\mathrm{V}_{\mathrm{OL}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{I}_{\mathrm{IN}}$, $I_{\mathrm{Cc}}$, and $\mathrm{l}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC259/MM74HC259

 8-Bit Addressable Latch/3-to-8 Line Decoder
## General Description

This device utilizes microCMOS Technology, 3.5 micron silicon gate P -well CMOS, to implement an 8 -bit addressable latch, designed for general purpose storage applications in digital systems.
The MM54HC259/MM74HC259 has a single data input (D), 8 latch outputs (Q1-Q8), 3 address inputs (A, B, and C), a common enable input ( $E$ ), and a common CLEAR input. To operate this device as an addressable latch, data is held on the $D$ input, and the address of the latch into which the data is to be entered is held on the $A, B$, and $C$ inputs. When ENABLE is taken low the data flows through to the addressed output. The data is stored when ENABLE transitions from low to high. All unaddressed latches will remain unaffected. With enable in the high state the device is deselected, and all latches remain in their previous state, unaffected by changes on the data or address inputs. To eliminate the possibility of entering erroneous data into the latches, the enable should be held high (inactive) while the address lines are changing.

## Connection Diagram

Dual-In-Line Package

MM54HC259/MM74HC259
54HC259 (J) 74HC259 (J,N)

## Truth Table

| Inputs |  | Outputs of <br> Addressed <br> Latch | Each <br> Other <br> Output | Function |
| :---: | :---: | :---: | :---: | :---: |
| H | $\bar{G}$ | L | D | $\mathrm{Q}_{i 0}$ |
| H | H | $\mathrm{Q}_{i 0}$ | $\mathrm{Q}_{i 0}$ | Memory |
| L | L | D | L | 8-Line Decoder |
| L | H | L | L | Clear |

If enable is held high and CLEAR is taken low all eight latches are cleared to a low state. If enable is low all latches except the addressed latch will be cleared. The addressed latch will instead follow the D input, effectively implementing a 3-to-8 line decoder.
All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 18 ns

■ Wide supply range: 2-6V

- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)

## Latch Selection Table

| Select Inputs |  | Latch <br> Addressed |  |
| :--- | :--- | :--- | :---: |
| C | B |  | 0 |
| L | L | L | 0 |
| L | L | H | 1 |
| L | H | L | 2 |
| L | H | H | 3 |
| H | L | L | 4 |
| H | L | H | 5 |
| H | H | L | 6 |
| H | H | H | 7 |

$H=$ high level, $L=$ low level
$D=$ the level at the data input
$Q_{i o}$ the level of $Q_{i}(i=0,1 \ldots 7$, as appropiate) before the indicated steady-state input conditions were established.

Absolute Maximum Ratings (Notes $1 \& 2$ )

| Supply Voltage (VCC) | -0.5 to +7.0 V |
| :---: | :---: |
| DC Input Voltage (VIN) | -1.5 to $\mathrm{V}_{\mathrm{CC}}+1.5 \mathrm{~V}$ |
| DC Output Voltage (VOUT) | -0.5 to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$ |
| Clamp Diode Current ( $\mathrm{I}_{\mathrm{K}}, \mathrm{l}_{\text {OK }}$ ) | $\pm 20 \mathrm{~mA}$ |
| DC Output Current, per pin (lout) | $\pm 25 \mathrm{~mA}$ |
| DC V ${ }_{\text {cc }}$ or GND Current, per pin (lcc) | $\pm 50 \mathrm{~mA}$ |
| Storage Temperature Range ( $\mathrm{T}_{\text {STG }}$ ) | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Power Dissipation (PD) (Note 3) | 500 mW |
| Lead Temperature ( $\mathrm{T}_{\mathrm{L}}$ ) (Soldering 10 s | onds) $\quad 260^{\circ} \mathrm{C}$ |

## Operating Conditions

| Icc | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & I_{O U T}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. ICC, and $\mathrm{l}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC266/MM74HC266 Quad 2-Input Exclusive NOR Gate

## General Description

This exclusive NOR gate utilizies microCMOS Technology, 3.5 micron silicon gate P-well CMOS, to achieve operating speeds similar to equivalent LS-TTL gates while maintaining the low power consumption and high noise immunity characteristic of standard CMOS integrated circuits. These gates are fully buffered and have a fanout of 10 LS-TTL loads. The MM54HC/MM74HC logic family is functionally as well as pin out compatible with the standard 54LS/74LS logic family. However, unlike the 'LS266 which is an open collector gate the 'HC266 has standard CMOS push-pull outputs. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 9 ns

■ Wide operating voltage range: 2-6V

- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $20 \mu \mathrm{~A}$ maximum ( 74 series)
- Output drive capability: 10 LS-TTL loads
- Push-pull output

## Connection Diagram

## MM54HC273/MM74HC273 Octal D Flip-Flops With Clear

## General Description

These edge triggered flip-flops utilize microCMOS Technology, 3.5 micron silicon gate P -well CMOS, to implement Dtype flip-flops. They possess high noise immunity, low power, and speeds comparable to low power Schottky TTL circuits. This device contains 8 master-slave flip-flops with a common clock and common clear. Data on the $D$ input having the specified setup and hold times is transferred to the Q output on the low to high transition of the CLOCK input. The CLEAR input when low, sets all outputs to a low state.
Each output can drive 10 low power Schottky TTL equivalent loads. The MM54HC273/MM74HC273 is functionally as well as pin compatible to the 54LS273/74LS273. All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

## Connection Diagram

Dual-In-Line Package.

54HC273 (J) $\quad \mathbf{7 4 H C 2 7 3 ( J , N ) ~}$

## Truth Table

(Each Flip-Flop)

| Inputs |  |  | Outputs |
| :---: | :---: | :---: | :---: |

| L | X | X | L |
| $H$ | $\uparrow$ | $H$ | $H$ |
| $H$ | $\uparrow$ | $L$ | L |
| $H$ | $L$ | $X$ | $Q_{0}$ |

$\mathrm{H}=$ High level (steady state)
L = Low level (steady state)
X = Don't Care
$\uparrow=$ Transition from iow to high level
$Q_{0}=$ The level of $Q$ before the indicated steadystate input conditions were established

## Features

Typical propagation delay: 18 ns

- Wide operating voltage range
n Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ ( 74 series)

■ Output drive: 10 LSTTL loads

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating _ plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OU}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $V_{I H}$ and $V_{I L}$ occur at $V_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $V_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{I}_{\mathrm{IN}}$. $I^{C C}$, and $\mathrm{l}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

AC Electrical Characteristics $\mathrm{V}_{C C}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=15$. $\mathrm{PF}, \mathrm{t}_{\mathrm{f}}=\mathrm{t}_{\mathrm{f}}=6$ ns (Note 6)

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2}+l_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C}{ }^{f+I_{C C} .}$
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC280/MM74HC280 9-Bit Odd/Even Parity Generator/Checker

## General Description

The MM54HC280/MM74HC280 utilizes microCMOS Technology, 3.5 micron silicon gate P -well CMOS, to achieve the high noise immunity and low power consumption of standard CMOS integrated circuits. It possesses the ability to drive 10 LS-TTL loads.
This parity generator/checker features odd/even outputs to facilitate operation of either odd or even parity applications. The word length capability is easily expanded by cascading devices. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function, and pinout compatible with the standard 54LS/74LS family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 28 ns
- Wide power supply range: $2 \mathrm{~V}-6 \mathrm{~V}$
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC )
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads

Connection Diagram

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## Logic Diagram

## MM54HC283/MM74HC283 4-Bit Binary Adder with Fast Carry

## General Description

This full adder performs the addition of two 4-bit binary numbers utilizing microCMOS Technology, 3.5 micron silicon gate P-well CMOS. The sum ( $\Sigma$ ) outputs are provided for each bit and the resultant carry (C4) is obtained from the fourth bit. These adders feature full internal look ahead across all four bits. This provides the system designer with partial look-ahead performance at the economy and reduced package count of a ripple-carry implementation.
The adder logic, including the carry, is implemented in its true form meaning that the end-around carry can be accomplished without the need for logic or level inversion. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Connection Diagram

## Features

- Full-carry look-ahead across the four bits
- Systems achieve partial look-ahead performance with the economy of ripple carry
- Wide supply range: 2 V to 6 V
- Low quiescent power consumption: $8 \mu \mathrm{~A}$ at $25^{\circ} \mathrm{C}$
- Low input current: $<1 \mu \mathrm{~A}$

Typical Add Times

| Two | Two |
| :--- | :---: |
| $8-$ Bit | $16-$ Bit |
| Words | Words |
| .25 ns | 45 ns |

Absolute Maximum Ratings (Notes 1 \& 2)
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )
DC Input Voltage ( $\mathrm{V}_{\mathrm{IN}}$ )
DC Output Voltage (VOUT)
Clamp Diode Current (liK, IOK)
DC Output Current, per pin (lout)
DC $V_{C C}$ or GND Current, per pin (ICC)
Storage Temperature Range (TSTG)
Power Dissipation ( $\mathrm{P}_{\mathrm{D}}$ ) (Note 3)
Lead Temperature ( $T_{L}$ ) (Soldering 10 seconds)
-0.5 to +7.0 V
-1.5 to $\mathrm{V}_{\mathrm{CC}}+1.5 \mathrm{~V}$
-0.5 to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$ $\pm 20 \mathrm{~mA}$ $\pm 25 \mathrm{~mA}$ $\pm 50 \mathrm{~mA}$
$-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ 500 mW $260^{\circ} \mathrm{C}$

| ICC | Maximum Quiescent Supply Current | $\begin{aligned} & \mathrm{V}_{I N}=V_{C C} \text { or GND } \\ & \mathrm{I}_{\mathrm{OUT}}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " $N$ " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN , $\mathrm{I}_{\mathrm{CC}}$ and $\mathrm{I}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

TL/F/5332-2

## MM54HC292/MM74HC292, MM54HC294/MM74HC294 Programmable Frequency Dividers/Digital Timers

## General Description

These high speed dividers/timers utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS. They possess the high noise immunity and low power consumption of standard CMOS integrated circuits, as well as the ability to drive 10 LS-TTL loads.
These programmable frequency dividers/digital timers contain 31 flip-flops ('HC292) or 15 flip.-flops ('HC294) plus 30 gates on a single chip. The count modulo is under digital control of the inputs provided.
Both types feature an active-low clear input to initialize the state of all flip-flops. To facilitate incoming inspection, test points are provided (TP1, TP2, and TP3 on the 'HC292 and TP on the 'HC294). These test points are not intended to drive system loads. Both types feature two clock inputs; either one may be used for clock gating. (See the truth table below.)

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function, and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Count divider chain
- Digitally programmable from $2^{2}$ to $2^{n}$ ( $\mathrm{n}=31$ for 'HC292, $\mathrm{n}=15$ for 'HC294)
- Usable frequency range from DC to 30 MHz
m Wide operating voltage range: $2 \mathrm{~V}-6 \mathrm{~V}$
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum
- Easily cascadable

Output drive capability: 10 LS-TTL loads

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( VOH , and VOU ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{H}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{H}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN , $\mathrm{I}_{\mathrm{CC}}$, and $\mathrm{I}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+I_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+l_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## Operation

A brief look at the digital timing capabilities will show that with a $1-\mathrm{MHz}$ input frequency, programming for $2^{10}$ will give a period of 1.024 ms , and $2^{20}$ will give a period of $1.05 \mathrm{~s}, 2^{26}$ will give a period of 1.12 min , and $2^{31}$ will give a period of 35.79 min .

The functional block diagram shows that the count modulo is controlled by an X/Y decoder connected to the modecontrol inputs of several flip-flops. These flip flops with mode controls each have a " $D$ " input connected to the parallel clock line and a " $T$ " input driven by the preceding stage. The parallel clock frequency is always the input frequency divided by four.

The X/Y decoder output selected by the programming inputs goes low. While a mode control is low, the " $D$ " input of the flip-flop is enabled, and the signal from the parallel clock line ( $f_{N} \div 4$ ) is passed to the " $T$ " input of the following stage. All the other mode controls are high enabling the " $T$ " inputs and causing each flip-flop in turn to divide by two.

## MM54HC298／MM74HC298 Quad 2－Multiplexers With Storage

## General Description

These high speed quad two input multiplexers with storage utilize microCMOS Technology， 3.5 micron silicon gate P－well CMOS．Both circuits feature high noise immunity and low power consumption associated with CMOS circuitry， along with speeds comparable to low power Schottky TTL logic．
These circuits are controlled by the signals WORD SELECT and CLOCK．When the WORD SELECT input is taken low Word 1 （A1，B1，C1 and D1）is presented to the inputs of the flip－flops，and when WORD SELECT is high Word 2 （A2，B2， C2 and D2）is presented to the inputs of the flip－flops．The selected word is clocked to the output terminals on the neg－ ative edge of the clock pulse．

All inputs are protected from damage due to static dis－ charge by diodes to $V_{C C}$ and ground．

## Features

－Typical propagation delay，
Clock to output： 20 ns
$\square$ Wide power supply range：2V－6V
a Low quiescent current：
$80 \mu \mathrm{~A}$ maximum（ 74 HC series）
B Low input current： $1 \mu \mathrm{~A}$ maximum

| $\mathrm{lcc}$ | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & I_{O U T}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{H}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{l} / \mathrm{N}$, $I_{C C}$, and $\mathrm{I}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.
Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C 2}{ }^{f+1}{ }_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C i+I_{C C}}$
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## Typical Applications

Figure 1 illustrates a BCD shift register that will shift an entire 4-bit BCD digit in one clock pulse.
When the word select input is high and the registers are clocked, the contents of register 1 is transferred (shifted) to register 2, etc. In effect, the BCD digits are shifted one position. In addition, this application retains a parallel-load capability which means that new BCD data can be entered into the entire register with one clock pulse. This arrangement can be modified to perform the shifting of binary data for any number of bit locations.

Another function that can be implemented with the MM54HC298/MM74HC298 is a register that can be designed specifically for supporting multiplier or division operations. Figure 2 is an example of a one place/two place shift register.
When word select is low and the register is clocked, the outputs of the arithmetic/logic units (ALU's) are shifted one place. When word select is high and the registers are clocked, the data is shifted two places.

FIGURE 1

FIGURE 2

## MM54HC299/MM74HC299

## 8-Bit TRI-STATE ${ }^{\circledR}$ Universal Shift Register

## General Description

This 8-bit TRI-STATE shift/storage register utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS. Along with the low power consumption and high noise immunity of standard CMOS integrated circuits, it has the ability to drive 15 LS-TTL loads. This circuit also features operating speeds comparable to the equivalent low power Schottky device.
The MM54HC299/MM74HC299 features multiplexed inputs/outputs to achieve full 8-bit data handling in a single 20 -pin package. Due to the large output drive capability and TRI-STATE feature, this device is ideally suited for interfacing with bus lines in a bus oriented system.
Two function select inputs and two output control inputs are used to choose the mode of operation as listed in the function table. Synchronous parallel loading is accomplished by taking both function select lines S0 and S1 high. This places the TRI-STATE outputs in a high impedance state, which
permits data applied to the input/output lines to be clocked into the register. Reading out of the register can be done while the outputs are enabled in any mode. A direct overriding CLEAR input is provided to clear the register whether the outputs are enabled or disabled.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- Typical operating frequency 40 MHz
- Typical propagation delay: 20 ns
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum (74HC)
- High output drive for bus applications
- Low quiescent current: $1 \mu \mathrm{~A}$ maximum

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " $N$ " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst-case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst-case $V_{I H}$ and $V_{I L}$ occur at $V_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $V_{I H}$ value at 5.5 V is 3.85 V .) The worst-case leakage current (IN. Icc, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

Note 6: Refer to Section 1 for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## Logic Diagram

## MM54HC354/MM74HC354, MM54HC356/MM74HC356 8-Channel TRI-STATE ${ }^{\circledR}$ Multiplexers with Latches

## General Description

The MM54HC354/MM74HC354 and MM54HC356/ MM74HC356 utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS. They exhibit the high noise immunity and low power dissipation of standard CMOS integrated circuits, along with the ability to drive 15 LS-TTL loads. Due to the large output drive capability and the TRI-STATE feature, these devices are ideally suited for interfacing with bus lines in a bus organized system.
These data selectors/multiplexers contain full on-chip binary decoding to select one of eight data sources. The data select address is stored in transparent latches that are enabled by a low level address on pin 11, $\overline{\mathrm{SC}}$. Data on the 8 input lines is stored in a parallel input/output register which in the MM54HC354/MM74HC354 is composed of 8 transparent latches enabled by a low level on pin $9, \overline{\mathrm{DC}}$, and in the MM54HC356/MM74HC356 is composed of 8 edge-triggered flip-flops, clocked by a low to high transition on pin 9 , CLK. Both true (Y) and complementary (W) TRI-STATE outputs are available on both devices.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pinout compatible with the standard 54LS/74LS-TTL logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Transparent latches on data select inputs
- Choice of data registers:

Transparent ('354)
Edge-triggered ('356)

- TRI-STATE complementary outputs with fan-out of 15 LS-TTL loads
- Typical propagation delay:

$$
\text { Data to output ('354): } 32 \mathrm{~ns}
$$

Clock to output ('346): 35 ns
■ Wide power supply range: $2 \mathrm{~V}-6 \mathrm{~V}$

- Low quiescent supply current: $80 \mu \mathrm{~A}$ maximum

■ Low input current: $1 \mu \mathrm{~A}$ maximum

| In | Maximum Input Current | $\mathrm{V}_{\text {IN }}=\mathrm{V}_{\text {CC }}$ or GND | 6.0 V |  | $\pm 0.1$ | $\pm 1.0$ | $\pm 1.0$ | $\mu \mathrm{A}$ |
| loz | Maximum TRI-STATE Output <br> Leakage Current | $\begin{aligned} & V_{\text {OUT }}=V_{\text {CC }} \text { or } \mathrm{GND} \\ & \mathrm{G}_{1}=\mathrm{V}_{\mathrm{CC}} \end{aligned}$ | 6.0 V |  | $\pm 0.5$ | $\pm 5.0$ | $\pm 10$ | $\mu \mathrm{A}$ |
| $I_{C C}$ | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & \mathrm{l}_{\mathrm{OUT}}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J" package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $V_{O H}$, and $V_{O L}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $V_{I H}$ and $V_{I L}$ occur at $V_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $V_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN . Icc, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

AC Electrical Characteristics $\mathrm{v}_{\mathrm{CC}}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6$ ns (Note 6)

## MM54HC365／MM74HC365 Hex TRI－STATE® Buffer MM54HC366／MM74HC366 Inverting Hex TRI－STATE Buffer MM54HC367／MM74HC367 Hex TRI－STATE Buffer MM54HC368／MM74HC368 Inverting Hex TRI－STATE Buffer

## General Description

These TRI－STATE buffers are general purpose high speed inverting and non－inverting buffers that utilize micro－ CMOS Technology， 3.5 micron silicon gate P－well CMOS． They have high drive current outputs which enable high speed operation even when driving large bus capacitances． These circuits possess the low power dissipation of CMOS circuitry，yet have speeds comparable to low power Schottky TTL circuits．All 4 circuits are capable of driving up to 15 low power Schottky inputs．
The MM54／74HC366 and the MM54／74HC368 are inverting buffers，where as the MM54／74HC365 and the MM54／ 74 HC 367 are non－inverting buffers．The MM54／74HC365 and the MM54／MM74HC366 have two TRI－STATE control in－ puts（ $\overline{\mathrm{G} 1}$ and $\overline{\mathrm{G} 2}$ ）which are NORed together to control all six
gates．The MM54／74HC367 and the MM54／74HC368 also have two output enables，but one enable（G1）controls 4 gates and the other（ $\overline{\mathrm{G} 2}$ ）controls the remaining 2 gates．
All inputs are protected from damage due to static dis－ charge by diodes to $V_{C C}$ and ground．

## Features

－Typical propagation delay： 15 ns
a Wide operating voltage range： $2 \mathrm{~V}-6 \mathrm{~V}$
－Low input current： $1 \mu \mathrm{~A}$ maximum
－Low quiescent current： $80 \mu \mathrm{~A}$ maximum（ 74 series）
－Output drive capability： 15 LS－TTL loads

| lin | Maximum Input Current | $\mathrm{V}_{\text {IN }}=\mathrm{V}_{\text {CC }}$ or GND | 6.0 V |  | $\pm 0.1$ | $\pm 1.0$ | $\pm 1.0$ | $\mu \mathrm{A}$ |
| loz | Maximum TRI-STATE Output Leakage Current | $\begin{aligned} & V_{O U T}=V_{C C} \text { or } G N D \\ & \mathbf{G}=V_{I H} \end{aligned}$ | 6.0 V |  | $\pm 0.5$ | $\pm 5.0$ | $\pm 10$ | $\mu \mathrm{A}$ |
| lcc | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & l_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise spectied all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J" package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN, ICC, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC373/MM74HC373 TRI-STATE® Octal D-Type Latch

## General Description

These high speed OCTAL D-TYPE LATCHES utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS. They possess the high noise immunity and low power consumption of standard CMOS integrated circuits, as well as the ability to drive 15 LS-TTL loads. Due to the large output drive capability and the TRI-STATE feature, these devices are ideally suited for interfacing with bus lines in a bus organized system.
When the LATCH ENABLE input is high, the Q outputs will follow the D inputs. When the LATCH ENABLE goes low, data at the $D$ inputs will be retained at the outputs until LATCH ENABLE returns high again. When a high logic level is applied to the OUTPUT CONTROL input, all outputs go to a high impedance state, regardiess of what signals are pres-
ent at the other inputs and the state of the storage elements.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function, and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{Cc}}$ and ground.

## Features

- Typical propagation delay: 18 ns
- Wide operating voltage range: 2 to 6 volts
n Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 series)

E Output drive capability: 15 LS-TTL loads

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{VOH}_{\mathrm{OH}}$, and $\mathrm{VOU}_{\mathrm{O}}$ occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{H}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{I H}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. icc. and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+I_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+I_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC374/MM74HC374 <br> TRI-STATE ${ }^{\circledR}$ Octal D-Type Flip-Flop

## General Description

These high speed Octal D-Type Flip-Flops utilize microCMOS Technology, 3.5 micron silicon gate P -well CMOS. They possess the high noise immunity and low power consumption of standard CMOS integrated circuits, as well as the ability to drive 15 LS-TTL loads. Due to the large output drive capability and the TRI-STATE feature, these devices are ideally suited for interfacing with bus lines in a bus organized system.
These devices are positive edge triggered flip-flops. Data at the $D$ inputs, meeting the setup and hold time requirements, are transferred to the Q outputs on positive going transitions of the CLOCK (CK) input. When a high logic level is applied to the OUTPUT CONTROL (OC) input, all outputs go to a high impedance state, regardless of what signals are present at the other inputs and the state of the storage elements.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function, and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 20 ns
m Wide operating voltage range: 2-6V
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum
- Compatible with bus-oriented systems
(1) Output drive capability: 15 LS-TTL loads

| IN | Maximum Input Current | $\mathrm{V}_{\text {IN }}=\mathrm{V}_{\text {CC }}$ or GND | 6.0 V |  | $\pm 0.1$ | $\pm 1.0$ | $\pm 1.0$ | $\mu \mathrm{A}$ |
| loz | Maximum TRISTATE Output Leakage Current | $\begin{aligned} & V_{I N}=V_{I H}, O C=V_{I H} \\ & V_{O U T}=V_{C C} \text { or } G N D \end{aligned}$ | 6.0 V |  | $\pm 0.5$ | $\pm 5$ | $\pm 10$ | $\mu \mathrm{A}$ |
| Icc | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or GND } \\ & l_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | $6.0 \mathrm{~V}$ |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " $J$ " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN , $\mathrm{I}_{\mathrm{CC}}$, and $\mathrm{l}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

AC Electrical Characteristics $\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{t}}=6$ ns (Note 6)

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+l_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{s}=C_{P D} V_{c C} f+I_{c c}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

MM54HC390/MM74HC390 Dual 4-Bit Decade Counter
MM54HC393/MM74HC393 Dual 4-Bit Binary Counter

## General Description

These counter circuits contain independent ripple carry counters and utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS. The MM54HC390/MM74HC390 incorporate dual decade counters, each composed of a di-vide-by-two and a divide-by-five counter. The divide-by-two and divide-by-five counters can be cascaded to form dual decade, dual bi-quinary, or various combinations up to a single divide-by-100 counter. The MM54HC393/M74HC393 contain two 4 -bit ripple carry binary counters, which can be cascaded to create a single divide-by-256 counter.
Each of the two 4-bit counters is incremented on the high to low transition (negative edge) of the clock input, and each has an independent clear input. When clear is set high all four bits of each counter are set to a low level. This enables count truncation and allows the implementation of divide-byN counter configurations.
Each of the counters outputs can drive 10 low power Schottky TTL equivalent loads. These counters are function-
aly as well as pin equivalent to the 54LS390/74LS390 and the 54LS393/74LS393, respectively. All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{C}}$ and ground.

## Features

- Typical operating frequency: 50 MHz
- Typical propagation delay: $13 \mathrm{~ns}\left(\mathrm{Ck}\right.$ to $\left.\mathrm{Q}_{\mathrm{A}}\right)$
- Wide operating supply voltage range: $2-6 \mathrm{~V}$
- Low input current: <1 $\mu \mathrm{A}$
- Low quiescent supply current: $80 \mu \mathrm{~A}$ maximum (74HC series)
- Fanout of 10 LS-TTL loads

| N | Maximum Input Current | $\mathrm{V}_{\text {IN }}=\mathrm{V}_{\text {CC }}$ or GND | 6.0 V |  | $\pm 0.1$ | $\pm 1.0$ | $\pm 1.0$ | $\mu \mathrm{A}$ |
| Icc | Maximum Quiescent Supply Current | $\begin{aligned} & V_{\text {IN }}=V_{C C} \text { or GND } \\ & I_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OU}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{I \mathrm{~L}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $l_{\mathrm{IN}}$, $\mathrm{I}_{\mathrm{CC}}$, and $\mathrm{I}_{\mathrm{OZ}}$ occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC423A/MM74HC423A <br> Dual Retriggerable Monostable Multivibrator

## General Description

The MM54/74HC423A high speed monostable multivibrators (one shots) utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS. They feature speeds comparable to low power Schottky TTL circuitry while retaining the low power and high noise immunity characteristic of CMOS circuits.
Each multivibrator features both a negative, $A$, and a positive, B, transition triggered input, either of which can be used as an inhibit input. Also included is a clear input that when taken low resets the one shot. The 'HC423 cannot be triggered from clear.
The 'HC423A is retriggerable. That is it may be triggered repeatedly while its outputs are generating a pulse and the pulse will be extended.
Pulse width stability over a wide range of temperature and supply is achieved using linear CMOS techniques. The output pulse equation is simply: $\mathrm{PW}=\left(\mathrm{R}_{\mathrm{EXT}}\right)\left(\mathrm{C}_{E X T}\right)$; where PW
is in seconds, $R$ is in ohms, and $C$ is in farads. All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 40 ns
w Wide power supply range: $2 \mathrm{~V}-6 \mathrm{~V}$
m Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)
m Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads
- Simple pulse width formula $T=R C$
- Wide pulse range: 400 ns to $\infty$ (typ)
- Part to part variation: $\pm 5 \%$ (typ)
m Schmitt Trigger A \& B inputs allow infinite rise and fa!! times on these inputs

Note 1: Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation Temperature Derating: Plastic " N " Package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$ Ceramic "J" Package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst-case output voltages ( $\mathrm{V}_{\mathrm{OH}}, \mathrm{VOU}_{\mathrm{O}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst-case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst-case leakage current ( $l_{\mathrm{IN}}$, I Cc , and $\mathrm{l}_{\mathrm{O}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

AC Electrical Characteristics $\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}_{\mathrm{V}}, \mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=15 \mathrm{PF}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{t}}=6$ ns

## Logic Diagram

TL/F/5206-5

## Theory of Operation

FIGURE 1

## TRIGGER OPERATION

As shown in Figure 1 and the logic diagram before an input trigger occurs, the one-shot is in the quiescent state with the Q output low, and the timing capacitor $\mathrm{C}_{\text {EXT }}$ completely charged to $V_{C C}$. When the trigger input $A$ goes from $V_{C C}$ to GND (while inputs $B$ and clear are held to $\mathrm{V}_{\mathrm{CC}}$ ) a valid trigger is recognized, which turns on comparator C 1 and N Channel transistor N1©. At the same time the output latch is set. With transistor N1 on, the capacitor $\mathrm{C}_{\text {EXT }}$ rapidly discharges toward GND until $\mathrm{V}_{\text {REF1 }}$ is reached. At this point the output of comparator Cl changes state and transistor N1 turns off. Comparator C1 then turns off while at the same time comparator C2 turns on. With transistor N1 off, the capacitor $\mathrm{C}_{\mathrm{EXT}}$ begins to charge through the timing resistor, $R_{E X T}$, toward $V_{C C}$. When the voltage across $C_{\text {EXT }}$ equals $\mathrm{V}_{\text {REF2 }}$, comparator C 2 changes state causing the output latch to reset ( $Q$ goes low) while at the same time disabling comparator C2. This ends the timing cycle with the one-shot in the quiescent state, waiting for the next trigger.
A valid trigger is also recognized when trigger input $B$ goes from GND to $V_{C C}$ (while input $A$ is at GND and input clear is at $V_{C C}{ }^{(8)}$.)
It should be noted that in the quiescent state $\mathrm{C}_{E X T}$ is fully charged to $\mathrm{V}_{\mathrm{CC}}$ causing the current through resistor $\mathrm{R}_{E X T}$ to be zero. Both comparators are "off" with the total device current due only to reverse junction leakages. An added feature of the 'HC423 is that the output latch is set via the input trigger without regard to the capacitor voltage. Thus, propagation delay from trigger to $Q$ is independent of the value of $\mathrm{C}_{E X T}, R_{E X T}$, or the duty cycle of the input waveform.

## RETRIGGER OPERATION

The 'HC423A is retriggered if a valid trigger occurs (3) followed by another trigger (4) before the Q output has returned to the quiescent (zero) state. Any retrigger, after the timing node voltage at pin or has begun to rise from $V_{\text {REF1 }}$, but has not yet reached $V_{\text {REF2 }}$, will cause an increase in output pulse width T . When a valid retrigger is initiated (1), the voltage at the $R / C_{E X T}$ pin will again drop to $V_{\text {REF }}$ before progressing along the RC charging curve toward $\mathrm{V}_{\mathrm{CC}}$. The $Q$ output will remain high until time $T$, after the last valid retrigger.

## RESET OPERATION

These one shots may be reset during the generation of the output pulse. In the reset mode of operation, an input pulse on clear sets the reset latch and causes the capacitor to be fast charged to $\mathrm{V}_{\mathrm{CC}}$ by turning on transistor Q1 (5. When the voltage on the capacitor reaches $\mathrm{V}_{\text {REF2 }}$, the reset latch will clear and then be ready to accept another pulse. If the clear input is held low, any trigger inputs that occur will be inhibited and the $Q$ and $\bar{Q}$ outputs of the output latch will not change. Since the Q output is reset when an input low level is detected on the Clear input, the output pulse $T$ can be made significantly shorter than the minimum pulse width specification.

Note: R and C are not subjected to temperature. The C is polypropolyne.

## MM54HC521/MM74HC521 8-Bit Magnitude Comparator (Equality Detector)

## General Description

This equality detector utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS, to compare bit for bit two 8 -bit words and indicates whether or not they are equal. The $\overline{\mathrm{P}=\mathrm{Q}}$ output indicates equality when it is low. A single active low enable is provided to facilitate cascading of several packages and enable comparison of words greater than 8 bits.
This device is useful in memory block decoding applications, where memory block enable signals must be generated from computer address information.
The comparator's output can drive 10 low power Schottky equivalent loads. This comparator is functionally and pin
compatible to the 54LS688/74LS688, All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 20 ns
- Wide power supply range: 2-6V
- Low quiescent current: $80 \mu \mathrm{~A}$ ( 74 series)
- Large output current: 4 mA ( 74 series)

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+I_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{s}=C_{P D} V_{C C} f+I_{C c}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC533／MM74HC533 TRI－STATE® Octal D－Type Latch with Inverted Outputs

## General Description

These high speed OCTAL D－TYPE LATCHES utilize microCMOS Technology， 3.5 micron silicon gate P－well CMOS．They possess the high noise immunity and low pow－ er consumption of standard CMOS integrated circuits，as well as the ability to drive 15 LS－TTL loads．Due to the large output drive capability and the TRI－STATE feature，these devices are ideally suited for interfacing with bus lines in a bus organized system．
When the LATCH ENABLE input is high，the $Q$ outputs will follow the inversion of the $D$ inputs．When the LATCH EN－ ABLE goes low，data at the D inputs will be retained at the outputs until LATCH ENABLE returns high again．When a high logic level is applied to the OUTPUT CONTROL input， all outputs go to a high impedance state，regardless of what signals are present at the other inputs and the state of the storage elements．

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed，function，and pinout compatible with the standard 54LS／74LS logic family．All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground．

## Features

－Typical propagation delay： 13 ns
－Wide operating voltage range： 2 to 6 volts
－Low input current： $1 \mu \mathrm{~A}$ maximum
－Low quiescent current： $80 \mu \mathrm{~A}$ ，maximum（ 74 HC series）
－Compatible with bus－oriented systems
－Output drive capability： 15 LS－TTL loads

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+I_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+I_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

National Semiconductor

## MM54HC534／MM74HC534 TRI－STATE® Octal D－Type Flip－Flop with Inverted Outputs

## General Description

These high speed Octal D－Type Flip－Flops utilize micro－ CMOS Technology， 3.5 micron silicon gate P－well CMOS． They possess the high noise immunity and low power con－ sumption of standard CMOS integrated circuits，as well as the ability to drive 15 LS－TTL loads．Due to the large output drive capability and the TRI－STATE feature，these devices are ideally suited for interfacing with bus lines in a bus orga－ nized system．
These devices are positive edge triggered flip－flops．Data at the D inputs，meeting the setup and hold time requirements， are transferred to the $\overline{\mathbf{Q}}$ outputs on positive going transi－ tions of the CLOCK（CK）input．When a high logic level is applied to the OUTPUT CONTROL（OC）input，all outputs go to a high impedance state，regardless of what signals are present at the other inputs and the state of the storage elements．

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed，function，and pinout compatible with the standard 54LS／74LS logic family．All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground．

## Features

－Typical propagation delay： 15 ns
－Wide operating voltage range：2－6V
－Low input current： $1 \mu \mathrm{~A}$ maximum
－Low quiescent current： $80 \mu \mathrm{~A}$ maximum
－Compatible with bus－oriented systems
（⿴囗十介 Output drive capability： 15 LS－TTL loads

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $\mathrm{I}_{1 \mathrm{~N}}$, Icc, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC540/MM74HC540 Inverting Octal TRI-STATE ${ }^{\circledR}$ Buffer MM54HC541/MM74HC541 Octal TRI-STATE Buffer

## General Description

These TRI-STATE buffers utilize microCMOS Technology, 3.5 micron silicon gate P -well CMOS. They possess high drive current outputs which enable high speed operation even when driving large bus capacitances. These circuits achieve speeds comparable to low power Schottky devices, while retaining the advantage of CMOS circuitry, i.e., high noise immunity, and low power consumption. Both devices have a fanout of 15 LS-TTL equivalent inputs.
The MM54HC540/MM74HC540 is an inverting buffer and the MM54HC541/MM74HC541 is a non-inverting buffer. The TRI-STATE control gate operates as a two-input NOR such that if either $\overline{\mathrm{G} 1}$ or $\overline{\mathrm{G} 2}$ are high, all eight outputs are in the high-impedance state.

In order to enhance PC board layout, the 'HC540 and 'HC541 offers a pinout having inputs and outputs on opposite sides of the package. All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 12 ns
- TRI-STATE outputs for connection to system buses
- Wide power supply range: 2-6V
(10w quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Output current: 6 mA

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Uniess otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{VOH}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN, $\mathrm{I}_{\mathrm{CC}}$, and $\mathrm{I}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## General Description

This octal transceiver utilizes microCMOS technology, 3.0 micron silicon gate N -well CMOS, and is intended for two-way asynchronous communication between data buses. These devices possess the low power consumption of CMOS circuitry, yet have speeds comparable to low power Schottky TTL circuits. They are output compatible with LS-TTL, and can drive up to 15 LS-TTL loads. All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.
The HC543 contains two sets of D-type latches for temporary storage of data flowing in either direction. Separate latch enable and output enable inputs are provided for each register to permit independent control of inputting and outputting in either direction of data flow.

For data flow from $A$ to $B$, for example, the A-to-B enable ( $\overline{E A B}$ ) input must be 'low' in order to enter data from A0-A7 or take data from B0-B7, as indicated in the I/O Control Table. With EAB low, a low signal on A-to-B latch enable ( $\overline{\mathrm{LEAB}}$ ) input makes the A -to- B latches transparent; a subsequent low-to-high transition of the $\overline{L E A B}$ signal puts the A latches in the storage mode and their outputs no longer change with the $A$ inputs. With $\overline{E A B}$ and $\overline{O E A B}$ both low, the TRI-STATE ${ }^{\circledR}$ B output buffers are active and reflect the data present at the output of the $A$ latches. Control of data flow from $B$ to $A$ is similar, but uses the $\overline{E B A}, \overline{L E B A}$ and $\overline{O E B A}$ inputs.

## Features

- Octal TRI-STATE outputs for $\mu \mathrm{P}$ bus applications
- Output drive capability: 15 LS-TTL loads
- Large output current: 6 mA
- Back-to-back registers for storage
- Separate controls for data flow in each direction

# MM54HC550/MM74HC550 Octal Registered Transceiver with Status Flags 

## General Description

This octal transceiver utilizes microCMOS technology, 3.0 micron silicon gate N -well.CMOS, and is intended for two-way asynchronous communication between data buses. These devices possess the low power consumption of CMOS circuitry, yet have speeds comparable to low power Schottky TTL circuits. They are output compatible with LS-TTL; and can drive up to 15 LS-TTL loads. All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.
The MM54HC550/MM74HC550 contain two 8-bit registers for temporary storage of data flowing in either direction. Each register has its own clock pulse and clock enable inputs, as well as a flag flip-flop that is set automatically as the register is loaded. Each flag flip-flop is provided with a clear input, and each register has a separate output enable control for its TRI-STATE ${ }^{\oplus}$ buffers. The separate clocks, flags and enables provide considerable flexibility as I/O ports for demand-response data transfer.
Data applied to the A inputs is entered and storect on the rising edge of the $A$ clock pulse (CPA), provided that the $A$ clock enable (CEA) is low; simultaneously, the status flipflop is set and the A-to-B flag (FAB) output goes high. Data
thus entered from the $A$ inputs is present at the inputs to the B output buffers, but appears only on the B I/O pins when the B output enable ( $\overline{\mathrm{OEB}}$ ) signal is made low. After the B output data is assimilated, the receiving system clears the A-to-B flag flip.flop by applying a low-to-high transition to the CFAB input. Optionally, the $\overline{O E A}$ and CFAB pins can be tied together and operated by one function from the receiving system.
Data flow from $B$-to-A proceeds in the same manner described for $A \cdot t o-B$ flow. Inputs $\overline{C E B}$ and $C P B$ enter the $B$ input data and set the B-to-A flag (FBA) output high. A low signal on $\overrightarrow{O E A}$ enables the $A$ output buffers and a low-tohigh transition on CFBA clears the FBA flag.

## Features <br> ■ Output drive: 15 LS-TTL loads <br> ■ Large output current: 6 mA <br> - Back-to-back registers for storage <br> - Register status flag flip-flops <br> - Separate edge-detecting clears for flag

## Dual-In-Line Package

## MM54HC551/MM74HC551 Octal Registered Inverting Transceiver with Status Flags

## General Description

This octal transceiver utilizes microCMOS technology, 3.0 micron silicon gate N -well CMOS, and is intended for two-way asynchronous communication between data buses. These devices possess the low power consumption of CMOS circuitry, yet have speeds comparable to low power Schottky TTL circuits. They are output compatible with LS-TTL, and can drive up to 15 LS-TTL loads. All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

The MM54HC551/MM74HC551 contain two 8-bit registers for temporary storage of data flowing in either direction. Each register has its own clock pulse and clock enable inputs, as well as a flag flip-flop that is set automatically as the register is loaded. Each flag flip-flop is provided with a clear input, and each register has a separate output enable control for its TRI-STATE ${ }^{\oplus}$ buffers. The separate clocks, flags and enables provide considerable flexibility as I/O ports for demand-response data transfer.

Data applied to the A inputs is entered and stored on the rising edge of the A clock pulse (CPA), provided that the A clock enable ( $\overline{\mathrm{CEA}})$ is low; simultaneously, the status flipflop is set and the A-to-B flag (FAB) output goes high. Data thus entered from the $A$ inputs is present at the inputs to
the $B$ output buffers, but appears only on the $B / / O$ pins when the $B$ output enable ( $\overline{\mathrm{OEB}}$ ) signal is made low. After the $B$ output data is assimilated, the receiving system clears the A-to-B flag flip-flop by applying a low-to-high transition to the CFAB input. Optionally, the $\overline{O E A}$ and CFAB pins can be tied together and operated by one function from the receiving system.

Data flow from B-to-A proceeds in the same manner described for $A$-to-B flow. Inputs $\overline{C E B}$ and $C P B$ enter the $B$ input data and set the B-to:A flag (FBA) output high. A low signal on $\overline{O E A}$ enables the A output buffers and a low-tohigh transition on CFBA clears the FBA flag.

## Features

- Inverting outputs

■ Output drive: 15 LS-TTL loads

- Large output current: 6 mA
a Back-to-back registers for storage

## MM54HC563／MM74HC563

## TRI－STATE ${ }^{\circledR}$ Octal D－Type Latch with Inverted Outputs

## General Description

These high speed OCTAL D－TYPE LATCHES utilize microCMOS Technology， 3.5 micron silicon gate P－well CMOS．They possess the high noise immunity and low pow－ er consumption of standard CMOS integrated circuits，as well as the ability to drive 15 LS－TTL loads．Due to the large output drive capability and the TRI－STATE feature，these devices are ideally suited for interfacing with bus lines in a bus organized system．
When the LATCH ENABLE（LE）input is high，the Q outputs will follow the inversion of the D inputs．When the LATCH ENABLE goes low，data at the $D$ inputs will be retained at the outputs until LATCH ENABLE returns high again．When a high logic lpvel is applied to the OUTPUT CONTROL（OC） input，all outputs go to a high impedance state，regardless of what signals are present at the other inputs and the state of the storage elements．

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed，function and pin－out compatible with the standard 54LS／74LS logic family．All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground．

## Features

－Typical propagation delay： 13 ns
－Wide operating voltage range： 2 to 6 volts
Low input current： $1 \mu \mathrm{~A}$ maximum
－Low quiescent current： $80 \mu \mathrm{~A}$ maximum（ 74 series）
$\pm$ Compatible with bus－oriented systems
－Output drive capability： 15 LS－TTL loads

## Truth Table

| Output <br> Control | Latch <br> Enable | Data | Output |
| :---: | :---: | :---: | :---: |
| L | H | H | L |
| L | H | L | H |
| L | L | X | Q̄0 |
| H | X | X | Z |

[^8]$Q_{0}=$ level of output before steady－state input conditions were established
$Z=$ high impedance

Note 1: Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$. and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $V_{I H}$ and $V_{I L}$ occur at $V_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $V_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (I ${ }_{I N}$, $I_{C c}$ and $\mathrm{I}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC564/MM74HC564

## TRI-STATE® Octal D-Type Flip-Flop with Inverted Outputs

## General Description

These octal D-type llip-flops utilize microCMOS Technology, 3.5 micron silicon gate $P$-well CMOS. They possess the high noise immunity and low power consumption of standard CMOS integrated circuits as well as the ability to drive 15 LS-TTL loads. Due to the large output drive capability and the TRI-STATE feature, these devices are ideally suited for interfacing with bus lines in a bus organized system.
These devices are positive edge triggered flip-flops. Data at the $D$ inputs, meeting the set-up and hold time requirements, are transferred to the $\overline{\mathbf{Q}}$ outputs on positive going transitions of the CLOCK (CK) input. When a high logic level is applied to the OUTPUT CONTROL (OC) input, all outputs go to a high impedance state, regardless of what signals are present at the other inputs and the state of the storage elements.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function, and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

■ Typical propagation delay: 15 ns

- Wide operating voltage range: $2 \mathrm{~V}-6 \mathrm{~V}$
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC Series)
- Compatible with bus-oriented systems
- Output drive capability: 15 LS-TTL loads
- Same as 576

Note 1: Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst-case output voltages $(\mathrm{VOH}$, and VOD occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst-case $V_{I H}$ and $V_{I L}$ occur at $V_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $V_{I H}$ value at 5.5 V is 3.85 V .) The worst-case leakage current ( $I_{\mathrm{N}}, l_{\mathrm{CC}}$, and $\mathrm{I}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

[^9]MM54HC573/MM74HC573 TRI-STATE ${ }^{\otimes}$ Octal D-Type Latch

## General Description

These high speed octal D-type latches utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS. They possess the high noise immunity and low power consumption of standard CMOS integrated circuits, as well as the ability to drive 15 LS-TTL loads. Due to the large output drive capability and the TRI-STATE feature, these devices are ideally suited for interfacing with bus lines in a bus organized system.
When the LATCH ENABLE(LE) input is high, the Q outputs will follow the D inputs. When the LATCH ENABLE goes low, data at the $D$ inputs will be retained at the outputs until LATCH ENABLE returns high again. When a high logic level is applied to the OUTPUT CONTROL OC input, all outputs go to a high impedance state, regardless of what signals are present at the other inputs and the state of the storage elements.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 13 ns
- Wide operating voltage range: 2 to 6 volts
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Compatible with bus-oriented systems
- Output drive capability: 15 LS-TTL loads

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " $N$ " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst-case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst-case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst-case leakage current (IIN. ICC, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC574/MM74HC574

TRI-STATE ${ }^{\circledR}$ Octal D-Type Flip-Flop

## General Description

These high speed octal D-type flip-flops utilize microCMOS Technology, 3.5 micron silicon gate P-well CMOS. They possess the high noise immunity and low power consumption of standard CMOS integrated circuits, as well as the ability to drive 15 LS-TTL loads. Due to the large output drive capability and the TRI-STATE feature, these devices are ideally suited for interfacing with bus lines in a bus organized system.
These devices are positive edge triggered flip-flops. Data at the D inputs, meeting the set-up and hold time requirements, are transferred to the Q outputs on positive going transitions of the CLOCK (CK) input. When a high logic level is applied to the OUTPUT CONTROL (OC) input, all outputs go to a high impedance state, regardless of what signals are present at the other inputs and the state of the storage elements.

The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function, and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 13 ns
- Wide operating voltage range: $2 \mathrm{~V}-6 \mathrm{~V}$
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum
- Compatible with bus-oriented systems
(1) Output drive capability: 15 LS-TTL loads

| loz | Maximum TRI-STATE Output Leakage Current | $\begin{aligned} & V_{\text {OUT }}=V_{\text {CC }} \text { or } \mathrm{GND} \\ & \mathrm{O}_{\mathrm{C}}=\mathrm{V}_{\mathrm{IH}} \end{aligned}$ | 6.0 V |  | $\pm 0.5$ | $\pm 5.0$ | $\pm 10$ | $\mu \mathrm{A}$ |
| Icc | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & I_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | - 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " $N$ " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst-case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst-case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst-case leakage current ( $\mathrm{IIN}_{\mathrm{N}}$ I ICc, and $\mathrm{IOz}_{\mathrm{O}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC589/MM74HC589 8-Bit Shift Registers with Input Latches and TRI-STATE ${ }^{\circledR}$ Serial Output

## General Description

This high speed shift register utilizes microCMOS Technolo$\mathrm{gy}, 3.5$ micron silicon gate P-well CMOS, to achieve the high noise immunity and low power consumption of standard CMOS integrated circuits, as well as the ability to drive 15 LS-TTL loads.
The 'HC589 comes in a 16-pin package and consists of an 8 -bit storage latch feeding a parallel-in, serial-out 8 -bit shift register. Data is serially entered on the SER pin. Both the storage register and shift register have positive-edge triggered clocks. The shift register also has direct load (from storage) and a TRI-STATE output to enable the wire-ORing of multiple devices on a serial bus.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function, and pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

n 8-Bit parallel storage register inputs

- Wide operating voltage range: $2 \mathrm{~V}-6 \mathrm{~V}$
- Shift register has direct overriding load
- Guaranteed shift frequency . . . DC to 30 MHz
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC Series)
- TRI-STATE output for 'Wire-OR'

|  |  | $\begin{aligned} & \mathrm{V}_{1 \mathrm{~N}}=\mathrm{V}_{1 \mathrm{H}} \text { or } \mathrm{V}_{\mathrm{IL}} \\ & \left\|\mathrm{I}_{\text {OUT }}\right\| \leq 4.0 \mathrm{~mA} \\ & \left\|I_{\text {IUT }}\right\| \leq 5.2 \mathrm{~mA} \end{aligned}$ | $\begin{aligned} & 4.5 \mathrm{~V} \\ & 6.0 \mathrm{~V} \end{aligned}$ |  | $\begin{array}{r} 0.26 \\ 0.26 \\ \hline \end{array}$ | $\begin{aligned} & 0.33 \\ & 0.33 \\ & \hline \end{aligned}$ | $\begin{aligned} & 0.4 \\ & 0.4 \end{aligned}$ | $\begin{aligned} & \text { V } \\ & \text { V } \end{aligned}$ |
| IN | Maximum Input Current | $\mathrm{V}_{\text {IN }}=\mathrm{V}_{\text {CC }}$ or GND | 6.0 V |  | $\pm 0.1$ | $\pm 1.0$ | $\pm 1.0$ | $\mu \mathrm{A}$ |
| Icc | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or GND } \\ & I_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | - 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OU}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (llN $I^{\mathrm{CC}}$, and $\mathrm{I}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

Functional Block Diagram (positive logic)

MM54HC589/MM74HC589

Logic Timing Diagram

# MM54HC590／MM74HC590 8－Bit Binary Counter with TRI－STATE ${ }^{\circledR}$ Output Register 

## General Description

These counters are implemented using an advanced 3.0 micron silicon gate N －well microCMOS process to achieve high performance．These devices retain the low power and high noise immunity of CMOS logic，while offering the high speed operation and large output drive typically associated with bipolar circuits．
The MM54HC590／MM74HC590 contain an 8－bit binary counter which feeds an 8 －bit register．The counter is in－ cremented on the rising edge of the CCK input，provided that clock enable，$\overline{\mathrm{CCKEN}}$ ，is low．When the counter increments to the all ones condition，ripple carry out，$\overline{\mathrm{RCO}}$ ，will go low． This enables either synchronous cascading of the counters by connecting the $\overline{R C O}$ of the first stage to the $\overline{C C K E N}$ of the second，or clocking both circuits in parallel．Ripple cascading is accomplished by connecting the $\overline{\mathrm{RCO}}$ of the first to the CCK of the second stage．A clear input is also provided which will reset the counter to the all zeros state．

The output register is loaded with the contents of the counter on the rising edge of the register clock，RCK．The outputs of this register feed TRI－STATE outputs which are enabled when the enable input，$G$ ，is taken low．This enables connection of this part to a system bus．

The MM54HC590／MM74HC590 are functional，speed and pin equivalent to the equivalent LS－TTL circuit．Its inputs are protected from damage due to the electrostatic discharge by diodes from $V_{C C}$ to ground．

## Features

Wide power supply range： 2.0 V to 6.0 V
－High input noise immunity
■ Wide operating frequency range： 30 MHz
－High output current drive： 6.0 mA min
－Low quiescent power consumption： $80 \mu \mathrm{~A}(74 \mathrm{HC})$

## Connection Diagram

MM54HC590/74HC590
Logic Diagram

# MM54HC592/MM74HC592 8-Bit Binary Counter with Input Register <br> MM54HC593/MM74HC593 8-Bit Binary Counter with Bidirectional Input Register/Counter Outputs 

## General Description

These counters are implemented using an advanced 3.0 micron sillicon gate $N$-well microCMOS process to achieve high performance. These devices retain the low power and high noise immunity of CMOS logic, while offering the high speed operation and large output drive typically assoclated with bipolar circuits.
The MM54HC592/MM74HC592 and the MM54HC593/ MM74HC593 contain an 8-bit register which feeds an 8-bit binary counter. The counter is incremented on the rising edge of the CCK input, provided that clock enable, $\overline{\mathrm{CCKEN}}$, is low. When the counter increments to the all ones condition, ripple carry out, $\overline{\mathrm{RCO}}$, will go low. This enables either synchronous cascading of the counters by connecting the $\overline{R C O}$ of the first stage to the CCKEN of the second, or clocking both circuits in parallel. Ripple cascading is accomplished by connecting the $\overline{\mathrm{RCO}}$ of the first to the CCK of the second stage. A clear input is also provided which will reset the counter to the all zeros state.
The input register is loaded on the rising edge of the register clock, RCK. The outputs of this register feed the counter. The counter is loaded with the register's contents when the clock load, $\overline{\mathrm{CLOAD}}$, input is taken low.

The 'HC592 differs from the 'HC593 in that the latter device has bidirectional input/output pins. The TRI-STATE ${ }^{\circledR}$ outputs of the counter can be enabled and are active when enable input, G , is taken low and input G is taken high. The outputs of the counter then appear on the register inputs. This enables connection of this part to a system bus. The 'HC593 also has a second clock enable pin, $\overline{C C K E N}$, which is active high and it also has an active low register clock enable, RCKEN.
The MM54HC592/MM74HC592 and the MM54HC593/ MM74HC593 are functional, speed and pin equivalent to the equivalent LS-TTL circuit. Their inputs are protected from damage due to electrostatic discharge by diodes from $V_{C C}$ to ground.

## Features

- Wide power supply range: 2.0 V to 6.0 V
- High input noise immunity

■. Wide operating frequency range: 30 MHz

- High output current drive: 6.0 mA min
- Low quiescent power consumption: $80 \mu \mathrm{~A}(74 \mathrm{HC})$

## Connection Diagrams

MM54/74HC592

## MM54HC595/MM74HC595 <br> 8-Bit Shift Registers with Output Latches

## General Description

This high speed shift register utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS. This device possesses the high noise immunity and low power consumption of standard CMOS integrated circuits, as well as the ability to drive 15 LS-TTL loads.
This device contains an 8 -bit serial-in, parallel-out shift register that feeds an 8-bit D-type storage register. The storage register has 8 TRI-STATE ${ }^{\text {© }}$ outputs. Separate clocks are provided for both the shift register and the storage register. The shift register has a direct-overriding clear, serial input, and serial output (standard) pins for cascading. Both the shift register and storage register use positive-edge triggered clocks. If both clocks are connected together, the shift register state will always be one clock pulse ahead of the storage register.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function, and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC Series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- 8-Bit Serial-In, Parallel-Out Shift Register With Storage
- Wide operating voltage range: $2 \mathrm{~V}-6 \mathrm{~V}$
- Cascadable
- Shift Register Has Direct Clear
- Guaranteed Shift Frequency: DC to 30 MHz

## connection Diagram

Dual-In-Line Package

TOP ViEw
TL/F/5342-1

54HC595 (J) 764HC595 (J,N)

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{H}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN , $I^{\prime} \mathrm{cc}$, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## AC Electrical Characteristics

$V_{C C}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$

Note 6: $C_{P D}$ dotermines the ro load dynamic power consumption, $P_{D}=C_{P O} V_{C C^{2}} f+I_{C C} V_{C C}$, and the no load dynamic current consumption, $s=C_{P D} V_{C C} f+I_{C C}$.
Note 7: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

TL/F/5342-3

## MM54HC597/MM74HC597 8-Bit Shift Registers with Input Latches

## General Description

This high speed shift register utilize microCMOS Technology, 3.5 micron silicon gate $\dot{\mathrm{P}}$-well CMOS. It has the high noise immunity and low power consumption of standard CMOS integrated circuits, as well as the ability to drive 10 LS-TTL loads.
The 'HC597 comes in a 16-pin package and consists of an 8 -bit storage latch feeding a parallel-in, serial-out 8 -bit shift register. Both the storage register and shift register have positive-edge triggered clocks. The shift register also has direct load (from storage) and clear inputs.
The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is speed, function, and pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $V_{C C}$ and ground.

## Features

- 8-Bit Parallel Storage Register Inputs
- Wide operating voltage range: $2 \mathrm{~V}-6 \mathrm{~V}$
- Shift Register has Direct Overriding Load and Clear
m Guaranteed Shift Frequency . . . DC to 30 MHz
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum

## Truth Table

| RCK | SCK | SLOAD | SCLR | Function |

| ICC | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or GND } \\ & I_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified a!l voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{VOH}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. $I_{C C}$, and $\mathrm{I}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## MM54HC640/MM74HC640 Inverting Octal TRI-STATE ${ }^{\circledR}$ Transceiver MM54HC643/MM74HC643 True-Inverting Octal TRI-STATE Transceiver

## General Description

These TRI-STATE bi-directional buffers utilize microCMOS Technology, 3.5 micron silicon gate P -well CMOS, and are intended for two-way asynchronous communication between data buses. They have high drive current outputs which enable high speed operation even when driving large bus capacitances. These circuits possess the low power consumption and high noise immunity usually associated with CMOS circuitry, yet have speeds comparable to low power Schottky TTL circuits.
Each device has an active enable $\bar{G}$ and a direction control input, DIR. When DIR is high, data flows from the A inputs to the $B$ outputs. When DIR is low, data flows from the $B$ inputs to the A outputs. The MM54HC640/MM74HC640 transfers inverted data from one bus to other and the MM54HC643/ MM74HC643 transfers inverted data from the A bus to the B bus and true data from the $B$ bus to the $A$ bus.

These devices can drive up to 15 LS-TTL Loads, and all inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 14 ns
- Wide power supply range: 2-6V
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC )

TRI-STATE outputs for connection to bus oriented systems
m High Output Drive: 6 mA (min)

## Connection Diagrams

Truth Table

| Control <br> Inputs |  | Operation |  |
| :---: | :---: | :---: | :---: |
| $\bar{G}$ | DIR | $\mathbf{6 4 0}$ | $\mathbf{6 4 3}$ |
| L | L | $\bar{B}$ data to A bus | B data to $A$ bus |
| L | H | $\overline{\text { A }}$ data to B bus | $\bar{A}$ data to B bus |
| H | X | Isolation | Isolation |

$H=$ high level, $L=$ low level, $X=$ irrelevant

Note 1: Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{VOH}_{\mathrm{O}}$, and $\mathrm{V}_{\mathrm{O}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{I H}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ vatue at 5.5 V is 3.85 V .) The worst case leakage current (IIN. $\mathrm{I}_{\mathrm{CC}}$, and $\mathrm{l}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

# MM54HC646/MM74HC646 Non-Inverting Octal Bus Transceiver/Registers MM54HC648/MM74HC648 Inverting Octal Bus Transceiver/Registers 

## General Description

These transceivers utilize microCMOS Technology, 3.5 mi cron silicon gate P -well CMOS, and contain two sets of TRISTATE ${ }^{\circledR}$ outputs, two sets of D-type flip-flops; and control circuitry designed for high speed multiplexed transmission of data.
Six control inputs enable this device to be used as a latched transceiver, unlatched transceiver, or a combination of both. As a latched transceiver, data from one bus is stored for later retrieval by the other bus. Alternately real time bus data (unlatched) may be directly transferred from one bus to another.
Circuit operation is determined by the G, DIR, CAB, CBA, SAB, SBA control inputs. The enable input, $G$, controls whether any bus outputs are enabled. The direction control, DIR, determines which bus is enabled, and hence the direction data flows: The SAB, SBA inputs control whether the latched data (stored in D type flip flops), or the bus data (from other bus input pins) is transferred. Each set of flip-
flops has its own clock CAB, and CBA, for storing data. Data is latched on the rising edge of the clock.
Each output can drive up to 15 low power Schottky TTL loads. These devices are functionally and pin compatible to their LS-TTL counterparts. All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 14 ns
- TRI-STATE outputs
- Bi-directional communication

■ Wide power supply range: 2-6V

- Low quiescent supply current: $160 \mu \mathrm{~A}$ maximum ( 74 HC )
- High output current: $6 \mathrm{~mA}(74 \mathrm{HC})$

## MM54HC688/MM74HC688

## 8-Bit Magnitude Comparator (Equality Detector)

## General Description

This equality detector utilizes microCMOS Technology, 3.5 micron silicon gate P -well CMOS, to compare bit for bit two 8 -bit words and indicates whether or not they are equal. The $\overline{\mathrm{P}=\mathrm{Q}}$ output indicates equality when it is low. A single active low enable is provided to facilitate cascading of several packages and enable comparison of words greater than 8 bits.
This device is useful in memory block decoding applications, where memory block enable signals must be generated from computer address information.
The comparator's output can drive 10 low power Schottky equivalent loads. This comparator is functionally and pin
compatible to the 54LS688/74LS688. All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

## Features

- Typical propagation delay: 20 ns
- Wide power supply range: 2-6V

L Low quiescent current: $80 \mu \mathrm{~A}$ ( 74 series)
m Large output current: 4 mA ( 74 series)

- Same as 'HC521

| Icc | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or GND } \\ & \mathrm{I}_{\mathrm{OUT}}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{i H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. ICC, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC4002/MM74HC4002 Dual 4-Input NOR Gate

## General Description

These NOR gates utilize microCMOS Technology, 3.5 mi cron silicon gate P -well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. All gates have buffered outputs, providing high noise immunity and the ability to drive 10 LS.TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard $54 \mathrm{LS} / 74 \mathrm{LS}$ logic family. The $54 \mathrm{HC} 4002 / 74 \mathrm{HC} 4002$ is functionally equivalent and pin-out compatible with the CD4002B. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 8 ns
- Wide power supply range: $2 \mathrm{~V}-6 \mathrm{~V}$
- Low quiescent current: $20 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads

## MM54HC4016/MM74HC4016 Quad Analog Switch

## General Description

These devices are digitally controlled analog switches implemented in microCMOS Technology, 3.5 micron silicon gate P-well CMOS. These switches have low 'on' resistance and low 'off' leakages. They are bidirectional switches, thus any analog input may be used as an output and vice-versa. The ' 4016 devices allow control of up to 12V (peak) analog signals with digital control signals of the same range. Each switch has its own control input which disables each switch when low. All analog inputs and outputs and digital inputs are protected from electrostatic damage by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Connection Diagram

Dual-In-Line Package

TOP VIEW
MM54HC4016/MM74HC4016
54HC4016(J) 74HC4016(J,N)

## Features

■ Typical switch enable time: 15 ns

- Wide analog input voltage range: $0-12 \mathrm{~V}$
- Low 'on' resistance: 50s2 typical

■ Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC )

- Matched switch characteristics
- Individual switch controls

Schematic Diagram

Absolute Maximum Ratings (Notes 1 \& 2)
Supply Voltage (VCc)
DC Control Input Voltage (VIN) -0.5 to +15 V

DC Switch I/O Voltage ( $\mathrm{V}_{10}$ )
Clamp Diode Current ( $I_{\mathrm{IK}}, \mathrm{I}_{\mathrm{OK}}$ ) DC Output Current, per pin (lout)
DC $V_{\text {CC }}$ or GND Current, per pin (ICC)
Storage Temperature Range ( $\mathrm{T}_{\mathrm{STG}}$ )
Power Dissipation ( $\mathrm{P}_{\mathrm{D}}$ ) (Note 3) 500 mW
Lead Temperature ( $T_{L}$ ) (Soldering 10 seconds) $260^{\circ} \mathrm{C}$

## Operating Conditions

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case on resistances ( $\mathrm{R}_{\mathrm{ON}}$ ) occurs for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. ( $T$ he $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current occur for CMOS at the higher voltage and so these values should be used.
Note 5: At supply voltages ( $\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{EE}}$ ) approaching 2 V the analog switch on resistance becomes extremely non-linear. Therefore it is recommended that these devices be used to transmit digital only when using these supply vottages.

## MM54HC4017/MM74HC4017 <br> Decade Counter/Divider with 10 Decoded Outputs

## General Description

The MM54HC4017/MM74HC4017 is a 5 -stage Johnson counter with 10 decoded outputs that utilizes micro-CMOS Technology, 3.5 micron silicon gate P-well CMOS. Each of the decoded outputs is normally low and sequentially goes high on the low to high transition of the clock input. Each output stays high for one clock period of the 10 clock period cycle. The CARRY output transitions low to high after OUTPUT 10 goes low, and can be used in conjunction with the CLOCK ENABLE to cascade several stages. The CLOCK ENABLE input disables counting when in the high state. A RESET input is also provided which when taken high sets all the decoded outputs low.
The MM54HC4017/MM74HC4017 is functionally and pinout equivalent to the CD4017BM/CD4017BC. It can drive
up to 10 low power Schottiky equivalent loads. All inputs are protected from damage due to static discharge by diodes from $V_{C C}$ and ground.

## Features

Wide power supply range: 2-6V

- Typical operating frequency: 30 MHz
m Fanout of 10 LS-TTL loads.
匹 Low quiescent current: $80 \mu \mathrm{~A}$ ( 74 HC series)
- Low input current: $1.0 \mu \mathrm{~A}$

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J" package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $V_{I H}$ and $V_{I L}$ occur at $V_{C C}=5.5 \mathrm{~V}$ and 4.5 V respectively. ( $T$ he $V_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. $\mathrm{I}_{\mathrm{CC}}$, and $\mathrm{I}_{\mathrm{Oz}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

TL/F/5351-2

# MM54HC4020/MM74HC4020 14 Stage Binary Counter MM54HC4024/MM74HC4024 7 Stage Binary Counter MM54HC4040/MM74HC4040 12 Stage Binary Counter 

## General Description

The MM54HC4020/74HC4020, MM54HC4024/74HC4024, MM54HC4040/74HC4040, are high speed binary ripple carry counters. These counters are implemented utilizing microCMOS Technology, 3.5 micron silicon gate $P$-well CMOS, to achieve speed performance similar to LS-TTL logic while retaining the low power and high noise immunity of CMOS.

The 'HC4020 is a 14 stage counter, the 'HC4040 is a 12 stage counter, and the 'HC4024 is a 7 stage counter. All these devices are incremented on the falling edge (negative transition) of the input clock, and all their outputs are reset to a low level by applying a logical high on their reset input.

These devices are pin equivalent to the CD4020, CD4024 and CD4040 respectively. All inputs are protected from damage due to static discharge by protection diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 16 ns

E Wide operating voltage range: 2-6V
n Low input current: $1 \mu \mathrm{~A}$ maximum

- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)
- Output drive capability: 10 LS-TTL loads

National Semiconductor MM54HC4046/MM74HC4046 CMOS Phase Lock Loop

## General Description

The MM54HC4046/MM74HC4046 is a low power phase lock loop utilizing $3.5 \mu$ silicon-gate P-well microCMOS Technology to obtain high frequency operation both in the phase comparator and VCO sections. This device contains a low power linear voltage controlled oscillator (VCO), a source follower, and three phase comparators. The three phase comparators have a common signal input and a common comparator input. The signal input has a self biasing amplifier allowing signals to be either capacitively coupled to the phase comparators with a small signal or directly coupled with standard input logic levels. This device is similar to the CD4046 except that the Zener diode of the metal gate CMOS device has been replaced with a third phase comparator.
Phase comparator I is an exclusive OR (XOR) gate. It provides a digital error signal that maintains a 90 phase shift between the VCO's center frequency and the input signal ( $50 \%$ duty cycle input) waveforms. This phase detector is more susceptible to locking onto harmonics of the input frequency than phase comparator I, but provides better noise rejection.

Phase comparator III is an SR flip-flop gate. It can be used to provide the phase comparator functions and is similar to the first comparator in performance.
Phase comparator II is an edge sensitive digital sequential network. Two signal outputs are provided, a comparator output and a phase pulse output. The comparator output is a TRI-STATE ${ }^{\circledR}$ output that provides a signal that locks the VCO output signal to the input signal with 0 phase shift
between them. This comparator is more susceptible to noise throwing the loop out of lock, but is less likely to lock onto harmonics than the other two comparators.
In a typical application all three comparators feed an external filter network which in turn feeds the VCO input. This input is a very high impedance CMOS input which also drives the source follower. The VCO's operating frequency is set by three external components connected to the C1A, C1B, R1 and R2 pins. An inhibit pin is provided to disable the VCO and the source follower, providing a method of putting the IC in a low power state.
The source follower is a MOS transistor whose gate is connected to the VCO input and whose drain connects the Demodulator output. This output normally is used by tying a resistor from pin 10 to ground, and provides a means of looking at the VCO input without loading down modifying the characteristics of the PLL filter.

## Features

a Low dynamic power consumption:

$$
\left(V_{c c}=4.5 \mathrm{~V}\right)
$$

■ Maximum VCO operating frequency: 20 MHz ( $\mathrm{V}_{\mathrm{CC}}=4.5 \mathrm{~V}$ )

- Fast comparator response time ( $\mathrm{V}_{\mathrm{CC}}=4.5 \mathrm{~V}$ ) Comparator I: 20 ns
Comparator II: 25 ns
Comparator III: 20 ns
$\square$ VCO has high linearity and high temperature stability

Note 1: Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{H}}$ and $\mathrm{V}_{\mathbb{L}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{I H}}$ value at 5.5 V is 3.85 V .) The worst case ieakage current (liN. $\mathrm{I}_{\mathrm{CC}}$, and $\mathrm{I}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## Detailed Circuit Description

VOLTAGE CONTROLLED OSCILLATOR/SOURCE FOLLOWER

The VCO requires two or three external components to operate. These are R1, R2, C1. Resistor 1 and capacitor C1 are selected to determine the center frequency of the VCO (see typical performance curves). R2 can be used to set the offset frequency with OV at VCO input. If R2 is omitted the VCO range is from 0 Hz ; as R2 is decreased, the offset frequency is increased. The effect of R2 is shown in the design information table and typical performance
curves. By increasing the value of R2 the lock range of the PLL is decreased and the gain (volts $/ \mathrm{Hz}$ ) is increased. Thus, for a narrow lock range, large swings on the VCO input will cause less frequency variation.
Internally, the resistors set a current in a current mirror, as shown in Figure 1. The mirrored current drives one side of

FIGURE 1. Logic Diagram for VCO

## Detailed Circuit Description (Continued)

the capacitor; once the capacitor charges up to the threshold of the Schmitt Trigger the oscillator logic flips the capacitor over and causes the mirror to charge the opposite side of the capacitor. The output from the internal logic is then taken to pin 4.
The input to the VCO is a very high impedance CMOS input and thus will not load down the loop filter, easing the filters design. In order to make signals at the VCO input accessible without degrading the loop performance, a source follower transistor is provided. This transistor can be used by connecting a resistor to ground and its drain output will follow the VCO input signal.
An inhibit signal is provided to allow disabling of the VCO and the source follower. This is useful if the internal VCO is not being used, but an external one is. A logic high on inhibit disables the VCO and source follower.
The output of the VCO is a standard high speed CMOS output with an equivalent LS-TTL fanout of 10 . The VCO
output is approximately a square wave. This output can either directly feed the comparator input of the phase comparators or feed external prescalers (counters) to enable frequency synthesis.

## PHASE COMPARATORS

All three phase comparators have two inputs, Signal In and Comparator In. The Signal In has a special DC bias network that enables $A C$ coupling of input signals. If the signals are not $A C$ coupled then this input requires logic levels the same as standard $54 \mathrm{HC} / 74 \mathrm{HC}$. The comparator input is a standard digital input. Both input structures are shown in Figure 3.
The outputs of these comparators are essentially standard $54 \mathrm{HC} / 74 \mathrm{HC}$ voltage outputs (comparator II is TRI-STATE).

## Detailed Circuit Description (Continued)

Thus in normal operation $V_{C C}$ and ground voltage levels are fed to the loop filter. This differs from some phase detectors which supply a current output to the loop filter and this should be considered in the design. (The CD4046 also provides a voltage.)
Figure 5 shows the state tables for all three comparators.

## PHASE COMPARATORI

This comparator is a simple XOR gate similar to the $54 /$ 74 HC 86 , and its operation is similar to an overdriven balanced modulator. To maximize lock range the input frequencies must have a $50 \%$ duty cycle. Typical input and output waveforms are shown in Figure 4. The output of the phase detector feeds the loop filter which averages the output voltage. The frequency range upon which the PLL will lock onto if initially out of lock is defined as the capture range. The capture range for phase detector I is dependent on the loop filter employed. The capture range can be as large as the lock range, which is equal to the VCO frequency range.
To see how the detector operates, refer to Figure 4. When two square wave inputs are applied to this comparator, an output waveform whose duty cycle is dependent on the phase difference between the two signals results. As the phase difference increases, the output duty cycle increases and the voltage after the loop filter increases. Thus, in order to achieve lock when the PLL input frequency increases the VCO input, voltage must increase
and the phase difference between comparator in and signal in will increase. At an input frequency equal to $\left\{_{\text {min }}\right.$, the VCO input is at $O V$. This requires the phase detector output to be grounded; hence, the two input signals must be in phase. When the input frequency is $f_{\text {max }}$, the VCO input must be $\mathrm{V}_{\mathrm{CC}}$ and the phase detector inputs must be $180^{\circ}$ out of phase.

The XOR is more susceptible to locking onto harmonics of the signal input than the digital phase detector II. For instance, a signal 2 times the VCO frequency results in the same output duty cycle as a signal equal to the VCO frequency. The difference is that the output frequency of the $2 f$ example is twice that of the other example. The loop filter and the VCO range should be designed to prevent locking on to harmonics.

## PHASE COMPARATOR II

This detector is a digital memory network. It consists of four flip-flops and some gating logic, a three state output and a phase pulse output as shown in Figure 6. This comparator acts only on the positive edges of the input signals and is thus independent of signal duty cycle.

Phase comparator II operates in such a way as to force the PLL into lock with 0 phase difference between the VCO output and the signal input positive waveform edges. Figure 7 shows some typical loop waveforms. First assume that the signal input phase is leading the comparator input. This

## Phase Comparator State Diagrams

FIGURE 5.

## Detailed Circuit Description (Continued)

means that the VCO's frequency must be increased to bring its leading edge into proper phase alignment. Thus the phase detector II output is set high. This will cause the loop filter to charge up the VCO input, increasing the VCO frequency. Once the leading edge of the comparator input is detected, the output goes TRI-STATE holding the VCO input at the loop filter voltage. If the VCO still lags the signal then the phase detector will again charge up to VCO input for the time between the leading edges of both waveforms.
If the VCO leads the signal then when the leading edge of the VCO is seen, the output of the phase comparator goes low. This discharges the loop filter until the leading edge of the signal is detected at which time the output disables itself again. This has the effect of slowing down the VCO to again make the rising edges of both waveforms coincidental.'

When the PLL is out of lock, the VCO will be running either slower or faster than the signal input. If it is running slower the phase detector will see more signal rising edges and so the output of the phase comparator will be high a majority of the time, raising the VCO's frequency. Conversely, if the VCO is running faster than the signal, the output of the detector will be low most of the time and the VCO's output frequency will be decreased.
As one can see, when the PLL is locked the output of phase comparator Il will be almost always disabled except for minor corrections at the leading edge of the waveforms. When the detector is TRI-STATE the phase pulse output is high. This output can be used to determine when the PLL is in the locked condition.

This detector has several interesting characteristics. Over the entire VCO frequency range there is no phase difference between the comparator input and the signal input. The lock range of the PLL is the same as the capture
range. Minimal power is consumed in the loop filter since in lock the detector output is a high impedance. Also, when no signal is present, the detector will see only VCO leading edges, so the comparator output will stay low, forcing the VCO to $f_{\text {min }}$ operating frequency.

Phase comparator II is more susceptible to noise, causing the phase lock loop to unlock. If a noise pulse is seen on the signal input, the comparator treats it as another positive edge of the signal and will cause the output to go high until the VCO leading edge is seen, potentially for a whole signal input period. This would cause the VCO to speed up during that time. When using the phase comparator $I$, the output of that phase detector would be disturbed for only the short duration of the noise spike and would cause less upset.

## PHASE COMPARATOR III

This comparator is a simple SR flip-flop which can function as a phase comparator as shown in Figure 8. It has some similar characteristics to the edge sensitive comparator. To see how this detector works, assume input pulses are applied to the signal and comparator inputs as shown in Figure 9. When the signal input leads the comparator input, the flop is set. This will charge up the loop filter and cause the VCO to speed up, bringing the comparator into phase with the signal input. When using short pulses as input, this comparator behaves very similarly to the second comparator. But one can see that if the signal input is a long pulse, the output of the comparator will be forced to a one no matter how many comparator input pulses are received. Also, if the VCO input is a square wave (as it is) and the signal input is pulse, then the VCO will force the comparator output low much of the time. Therefore, it is ideal to condition the signal and comparator input to short pulses. This is most easily done by using a series capacitor.

## MM54HC4049/MM74HC4049 Hex Inverting Logic Level Down Converter MM54HC4050/MM74HC4050 Hex Logic Level Down Converter

## General Description

The MM54HC4049/MM74HC4049 and the MM54HC4050/ MM74HC4050 utilize microCMOS Technology, 3.5 micron silicon gate $P$-well CMOS, and have a modified input protection structure that enables these parts to be used as logic level translators which will convert high level logic to a low level logic while operating from the low logic supply. For example, 0-15V CMOS logic can be converted to 0-5V logic when using a 5 V supply. The modified input protection has no diode connected to $V_{C C}$ thus allowing the input voltage to exceed the supply. The lower zener diode protects the input from both positive and negative static voltages. In addition each part can be used as a simple buffer or inverter without level translation. The MM54HC4049/MM74HC4049
is pin and functionally compatible to the CD4049BM/ CD4049BC and the MM54HC4050/MM74HC4050 is compatible to the CD4050BM/CD4050BC

## Features

a Typical propagation delay: 8 ns

- Wide power supply range: $2 \mathrm{~V}-6 \mathrm{~V}$
- Low quiescent supply current: $20 \mu \mathrm{~A}$ maximum ( 74 HC )
- Fanout of 10 LS-TTL loads

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J" package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$ and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{iH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathrm{IH}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN. $\mathrm{lcc}, \mathrm{loz}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

# MM54HC4051/MM74HC4051 8 Channel Analog Multiplexer MM54HC4052/MM74HC4052 Dual 4 Channel Analog Multiplexer MM54HC4053/MM74HC4053 Triple 2 Channel Analog Multiplexer 

## General Description

These multiplexers are digitally controlled analog switches implemented in microCMOS Technology, 3.5 micron silicon gate P-well CMOS. These switches have low "on" resistance and low "off" leakages. They are bidirectional switches, thus any analog input may be used as an output and vice-versa. Also these switches contain linearization circuitry which lowers the on resistance and increases switch linearity. These devices allow control of up to $\pm 6 \mathrm{~V}$ (peak) analog signals with digital control signals of 0 to 6 V . Three supply pins are provided for $\mathrm{V}_{\mathrm{CC}}$, Ground, and $\mathrm{V}_{\mathrm{EE}}$. This enables the connection of $0-5 \mathrm{~V}$ logic signals when $V_{C C}=5 \mathrm{~V}$ and an analog input range of $\pm 5 \mathrm{~V}$ when $\mathrm{V}_{\mathrm{EE}}=5 \mathrm{~V}$. All three devices also have an inhibit control which when high will disable all switches to their off state. All analog inputs and outputs and digital inputs are protected from electrostatic damage by diodes to $V_{C C}$ and ground. MM54HC4051/MM74HC4051: This device connects together the outputs of 8 switches, thus achieving an 8 Channel Multiplexer. The binary code placed on the A, B, and C select lines determines which one of the eight switches is "on". and connects one of the eight inputs to the common output. MM54HC4052/MM74HC4052: This device connects together the outputs of 4 switches in two sets, thus achieving
a pair of 4 channel multiplexers. The binary code placed on the A , and B select lines determine which switch in each 4 channel section is "on", connecting one of the four inputs in each section to its common output. This enables the implementation of a 4 channel differential multiplexer.
MM54HC4053/MM74HC4053: This device contains 6 switches whose outputs are connected together in pairs, thus implementing a triple 2 channel multiplexer, or the equivalent of 3 single-pole-double throw configuration. Each of the $A, B$, or C select lines independently controls one pair of switches, selecting one of the two switches to be "on".

## Features

- Wide analog input voltage range: $\pm 6 \mathrm{~V}$
- Low "on" resistance: 50 typ. ( $\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{EE}}=4.5 \mathrm{~V}$ )

30 typ. $\left(\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{EE}}=9 \mathrm{~V}\right)$

- Logic level translation to enable 5 V logic with $\pm 5 \mathrm{~V}$ analog signals
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC )
- Matched Switch characteristic

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case on resistances ( $\mathrm{R}_{\mathrm{ON}}$ ) occurs for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current occur for CMOS at the higher voltage and so the 5.5 V values should be used.
Note 5: At supply voltages ( $\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{EE}}$ ) approaching 2V the analog switch on resistance becomes extremely non-linear. Therefore it is recommended that these devices be used to transmit digital only when using these suppiy voltages.

## AC Electrical Characteristics

## MM54HC4060/MM74HC4060 14 Stage Binary Counter

## General Description

The MM54HC4060/MM74HC4060 is a high speed binary ripple carry counter. These counters are implemented utilizing microCMOS technology, 3.5 micron silicon gate P -well CMOS, to achieve speed performance similar to LS-TTL logic while retaining the low power and high noise immunity of CMOS.

The 'HC4060 is a 14 -stage counter which increments on the falling edge (negative transition) of the input clock, and all their outputs are reset to a low level by applying a logical high on their reset input. The 'HC4060 also has two additional inputs to enable easy connection of either an RC or crystal oscillator.

[^14]
## General Description

These devices are digitally controlled analog switches utiliz－ ing microCMOS Technology， 3.5 micron silicon gate P－well CMOS．These switches have low＂on＂resistance and low ＂off＂leakages．They are bidirectional switches，thus any analog input may be used as an output and visa－versa．Also the＇ 4066 switches contain linearization circuitry which low－ ers the＂on＂resistance and increases switch linearity．The ＇4066 devices allow control of up to 12 V （peak）analog sig－ nals with digital control signals of the same range．Each switch has its own control input which disables each switch when low．All analog inputs and outputs and digital inputs are protected from electrostatic damage by diodes to $V_{C C}$ and ground．

## Features

－Typical switch enable time： 15 ns
－Wide analog input voltage range：0－12V
■ Low＂on＇resistance： 30 typ．（＇4066）
－Low quiescent current： $80 \mu \mathrm{~A}$ maximum（ 74 HC ）
－Matched switch characteristics
－Individual switch controls

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case on resistance ( $\mathrm{R}_{\mathrm{ON}}$ ) occurs for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{I}}$ value at 5.5 V is 3.85 V .) The worst case leakage current occurs for CMOS at the higher voltage and so the 5.5 V values should be used.
Note 5: At supply voltages ( $\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{EE}}$ ) approaching 2 V the analog switch on resistance becomes extremely non-linear. Therefore it is recommended that these devices be used to transmit digital only when using these supply voltages.

## Typical Performance Characteristics

## MM54HC4075/MM74HC4075 Triple 3-Input OR Gate

## General Description

These OR gates utilize microCMOS Technology, 3.5 micron silicon gate P -well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. All gates have buffered outputs, providing high noise immunity and the ability to drive 10 LS-TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard 54LS/ 74LS logic family. The $54 \mathrm{HC} 4075 / 74 \mathrm{HC} 4075$ is functionally equivalent and pin-out compatible with the CD4075B and MC14075B metal gate CMOS devices. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 11 ns
- Wide power supply range: $2 \mathrm{~V}-6 \mathrm{~V}$

E Low quiescent current: $20 \mu \mathrm{~A}$ maximum ( 74 HC series)

- Low input current: 1. $\mu \mathrm{A}$ maximum

E Fanout of 10 LS-TTL loads

|  |  | $\begin{aligned} & \mathrm{V}_{\text {IN }}=\mathrm{V}_{1 \mathrm{H}} \text { or } \mathrm{V}_{\mathrm{IL}} \\ & \left\|\mathrm{I}_{\text {OUT }}\right\| \leq 4.0 \mathrm{~mA} \\ & \left\|\mathrm{I}_{\text {OUT }}\right\| \leq 5.2 \mathrm{~mA} \end{aligned}$ | $\begin{aligned} & 4.5 \mathrm{~V} \\ & 6.0 \mathrm{~V} \end{aligned}$ | $\begin{aligned} & 0.2 \\ & 0.2 \end{aligned}$ | $\begin{aligned} & 0.26 \\ & 0.26 \end{aligned}$ | $\begin{aligned} & 0.33 \\ & 0.33 \end{aligned}$ | $\begin{aligned} & 0.4 \\ & 0.4 \end{aligned}$ | $\begin{aligned} & \text { V } \\ & \text { V } \end{aligned}$ |
| IN | Maximum Input Current | $\mathrm{V}_{\text {IN }}=\mathrm{V}_{\text {CC }}$ or GND | 6.0 V |  | $\pm 0.1$ | $\pm 1.0$ | $\pm 1.0$ | $\mu \mathrm{A}$ |
| Icc | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & I_{O U T}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 2.0 | 20 | 40 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current ( $l_{\mathrm{I}} \mathrm{N}$, $\mathrm{I}_{\mathrm{Cc}}$, and (OZ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+I_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+I_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## General Description

These NOR gates utilize microCMOS Technology, 3.5 mi cron silicon gate P -well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits. Both outputs are buffered, providing high noise immunity and the ability to drive 10 LS-TTL loads. The $54 \mathrm{HC} 4078 / 74 \mathrm{HC} 4078$ is functionally equivalent and pin-out compatible with the CD4078B. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC4316/MM74HC4316 Quad Analog Switch wwith Level Translator

## General Description

These devices are digitally controlled analog switches implemented in microCMOS Technology, 3.5 micron silicon gate P-well CMOS. These switches have low "on" resistance and low "off" leakages. They are bidirectional switches, thus any analog input may be used as an output and vice-versa. Three supply pins are provided on the '4316 to implement a level translator which enables this circuit to operate with $0-6 \mathrm{~V}$ logic levels and up to $\pm 6 \mathrm{~V}$ analog switch levels. The ' 4316 also has a common enable input in addition to each switch's control which when low will disable all switches to their off state. All analog inputs and outputs and digital inputs are protected from electrostatic damage by diodes to $V_{C C}$ and ground.

## Connection Diagram

Dual-In-Line Package

## Features

- Typical switch enable time: 20 ns
- Wide analog input voltage range: $\pm 6 \mathrm{~V}$
- Low "on" resistance: 50 typ. ( $\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{EE}}=4.5 \mathrm{~V}$ ) 30 typ. ( $\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{EE}}=9 \mathrm{~V}$ )
■ Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HC )
- Matched switch characteristics
- Individual switch controls plus a common enable

## Truth Table

| Inputs |  | Switch |
| :---: | :---: | :---: |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.

Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case on resistances ( $\mathrm{RON}_{\mathrm{ON}}$ ) occurs for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current occurs for CMOS at the higher voltage and so the 5.5 V values should be used.
Note 5: At supply voltages ( $\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{EE}}$ ) approaching 2 V the analog switch on resistance becomes extremely non-linear. Therefore it is recommended that these devices be used to transmit digital only when using these supply voltages.

## AC Electrical Characteristics

## MM54HC4351／MM74HC4351 <br> 8 Channel Analog Multiplexer with Latches MM54HC4352／MM74HC4352 <br> Dual 4 Channel Analog Multiplexer with Latches MM54HC4353／MM74HC4353 <br> Triple 2 Channel Analog Multiplexer with Latches

## General Description

These multiplexers are digitally controlled analog switches implemented in microCMOS Technology， 3.5 micron silicon gate P－well CMOS．These switches have low＂on＂resist－ ance and low＂off＂leakages．They are bidirectional switches，thus any analog input may be used as an output and vice－versa．Also these switches contain linearization cir－ cuitry which lowers the＂on＂resistance and increases switch linearity．These devices allow control of up to $\pm 6 \mathrm{~V}$ （peak）analog signals with digital control signals of 0 to 6 V ． The analog channel select lines are latched to enable stor－ age of the selected channel．This storage register is com－ posed of flow through latches that follow the data when $\overline{L E}$ is high and latch the data when $\overline{L E}$ is taken low．
Three supply pins are provided for $V_{C C}$ ，Ground，and $V_{E E}$ ． This enables the connection of $0-5 \mathrm{~V}$ logic signals when $V_{C C}=5 \mathrm{~V}$ and an analog input range of $\pm 5 \mathrm{~V}$ when $\mathrm{V}_{\mathrm{EE}}=-5 \mathrm{~V}$ ．All three devices also have an inhibit control which when high will disable all switches to their off state． All analog inputs and outputs and digital inputs are protect－ ed from electrostatic damage by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground． MM54HC4351／MM74HC4351：This device connects together the outputs of 8 switches，thus achieving an 8 channel multi－ plexer．The binary code placed on the A，B，and Cselect lines determine which one of the eight switches is＂on＂，and connects one of the eight inputs to the common output．
MM54HC4352／MM74HC4352：This device connects to－ gether the outputs of 4 switches in two sets，thus achieving
a pair of 4 channel multiplexers．The binary code placed on the $A$ ，and $B$ select lines determine which switch in each 4 channel section is＂on＂，connecting one of the four inputs in each section to its common output．This enables the imple－ mentation of a 4 channel differential multiplexer．
MM54HC4353／MM74HC4353：This device contains 6 switches whose outputs are connected together in pairs， thus implementing a triple 2 channel multiplexer，or the equivalent of a single－pole－double throw configuration．Each of the A，B，or C select lines independently controls one pair of switches，selecting one of the two switches to be＂on＂．

## Features

－Typical Switch Enable Time： 18 ns
$\square$ Wide analog input voltage range：$\pm 6 \mathrm{~V}$
－Low＂on＂resistance： 50 typ．（ $\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{EE}}=4.5 \mathrm{~V}$ ）
30 typ．$\left(V_{C C}-V_{E E}=9 V\right)$
－Logic level translation to enable 5 V logic with $\pm 5$ ana－ log signals
－Low quiescent current： $80 \mu \mathrm{~A}$ max．（74HC）
$\pm$ Matched Switch characteristics．
－Latched Select Lines to enable interface to multiplexed data buses．

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J" package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case on resistances ( $\mathrm{R}_{\mathrm{ON}}$ ) occurs for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current occur for CMOS at the higher voltage and so the 5.5 V values should be used.
Note 5: At supply voltages ( $\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{EE}}$ ) approaching 2 V the analog.switch on resistance becomes extremely non-linear. Therefore it is recommended that these devices be used to transmit digital only when using these supply voltages.

## MM54HC4514/MM74HC4514 4-to-16 Line Decoder with Latch

## General Description

This utilizes microCMOS Technology, 3.5 micron silicon gate P-well CMOS decoder, which is well suited to memory address decoding or data routing application. It possesses high noise immunity and low power dissipation usually associated with CMOS circuitry, yet speeds comparable to low power Schottky TTL circuits. It can drive up to 10 LS-TTL loads.
The MM54HC4514/MM74HC4514 contain a 4-to-16 line decoder and a 4-bit latch. The latch can store the data on the select inputs, thus allowing a selected output to remain high even though the select data has changed. When the LATCH ENABLE input to the latches is high the outputs will change with the inputs. When LATCH ENABLE goes low the data on the select inputs is stored in the latches. The four select inputs determine which output will go high provided the

INHIBIT input is low. If the INHIBIT input is high all outputs are held low thus disabling the decoder.
The MM54HC4514/MM74HC4514 is functionally and pinout equivalent to the CD4514BM/CD4514BC and the MC1451BA/ MC1451BC. All inputs are protected against damage due to static discharge diodes from $V_{C C}$ and ground.

## Features

- Typical propagation delay: 18 ns

■ Low quiescent power: $80 \mu \mathrm{~A}$ maximum ( 74 HC series)

- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS.TTL loads ( 74 HC series)

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+I_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+I_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HC4538/MM74HC4538 Dual Retriggerable Monostable Multivibrator

## General Description

The MM54HC4538/MM74HC4538 high speed monostable multivibrators (one shots) are implemented in microCMOS Technology, 3.5 micron silicon gate P -well CMOS. They feature speeds comparable to low power Schottky TTL circuitry while retaining the low power and high noise immunity characteristic of CMOS circuits.
Each multivibrator features both a negative, A , and a positive, B, transition triggered input, either of which can be used as an inhibit input. Also included is a clear input that when taken low resets the one shot. The 'HC4538 is retriggerable. That is, it may be triggered repeatedly while their outputs are generating a pulse and the pulse will be extended.
Pulse width stability over a wide range of temperature and supply is achieved using linear CMOS techniques. The out-

$\downarrow=$ Transistion from High to Low
put pulse equation is simply: $\mathrm{PW}=0.7(\mathrm{R})(\mathrm{C})$ where PW is in seconds, $R$ is in Ohms, and C is in Farads. This device is pin compatible with the CD4528, and the CD4538 one shots. All inputs are protected from damage due to static discharge by diodes to Vcc and ground.

## Features

- Schmitt trigger on $A$ and $B$ inputs
- Wide power supply range: 2-6V
- Typical Trigger Propagation Delay: 32 ns
- Fanout of $10 \mathrm{LS}-\mathrm{TTL}$ loads ( 74 HC )
- Low Input current: $1 \mu \mathrm{~A}$ max

AC Electrical Characteristics $\mathrm{C}_{\mathrm{L}}=50 \mathrm{pF} \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$ (Unless otherwise specified)

Note 5: $C_{P D}$ determines the no load dynamic consumption, $P_{D}=C_{P D} V_{C C}{ }^{2 f}+I_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=V_{C C}{ }^{f}+I_{C C}$
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## Logic Diagram

## Circuit Operation

The＇HC4538 operates as follows（refer to logic diagram）．In the quiescent state，the external timing capacitor， $\mathrm{C}_{\mathrm{X}}$ ，is charged to $\mathrm{V}_{\mathrm{C}}$ ．When a trigger occurs，the Q output goes high and $\mathrm{C}_{\mathrm{X}}$ discharges quickly to the lower reference volt－ age（ $V_{\text {REF }}$ Lower $=1 / 3 V_{C C}$ ）．$C_{X}$ then charges，through $R_{X}$ ， back up to the upper reference voltage（ $V_{\text {REF }}$ Upper $=2 / 3$ $\mathrm{V}_{\mathrm{CC}}$ ），at which point the one－shot has timed out and the Q output goes low．
The following，more detailed description of the circuit opera－ tion refers to both the logic diagram and the timing diagram．

## QUIESCENT STATE

In the quiescent state，before an input trigger appears，the output latch is high and the reset latch is high（\＃1 in logic diagram）．
Thus the Q output（pin 6 or 10）of the monostable multivibra－ tor is low（\＃2，timing diagram）．

The output of the trigger－control circuit is low（\＃3），and tran－ sistors M1，M2，and M3 are turned off．The external timing capacitor，$C_{X}$ ，is charged to $V_{C C}(\# 4)$ ，and the upper refer－ ence circuit has a low output（\＃5）．Transistor M4 is turned on and transmission gate T1 is turned off．Thus the lower reference circuit has $\mathrm{V}_{\mathrm{CC}}$ at the noninverting input and a resulting low output（\＃6）．
In addition，the output of the trigger－control reset circuit is low．

## TRIGGER OPERATION

The＇HC4538 is triggered by either a rising－edge signal at input A（\＃7）or a falling－edge signal at input B（\＃8），with the unused trigger input and the Reset input held at the voltage levels shown in the Function Table．Either trigger signal will cause the output of the trigger－control circuit to go high （\＃9）．

## Timing Diagram

## Circuit Operation (Continued)

The trigger-control circuit going high simultaneously initiates three events. First, the output latch goes low, thus taking the Q output of the 'HC4538 to a high state (\#10). Second, transistor M3 is turned on, which allows the external timing capacitor, $\mathrm{C}_{X}$, to rapidly discharge toward ground (\#11). (Note that the voltage across $\mathrm{C}_{\mathrm{X}}$ appears at the input of the upper reference circuit comparator). Third, transistor M4 is turned off and transmission gate T1 is turned on, thus allowing the voltage across $C_{X}$ to also appear at the input of the lower reference circuit comparator.
When $\mathrm{C}_{\mathrm{X}}$ discharges to the reference voltage of the lower reference circuit (\#12), the outputs of both reference circuits will be high (\#13). The trigger-control reset circuit goes high, resetting the trigger-control circuit flip-flop to a low state (\#14). This turns transistor M3 off again, allowing $C_{X}$ to begin to charge back up toward $\mathrm{V}_{\mathrm{CC}}$, with a time constant $t=R_{X} C_{X}(\# 15)$. In addition, transistor M4 is turned on and transmission gate T 1 is turned off. Thus a high voltage level is applied to the input of the lower reference circuit comparator, causing its output to go low (\#16). The monostable multivibrator may be retriggered at any time after the triggercontrol circuit goes low.
When $C_{X}$ charges up to the reference voltage of the upper reference circuit (\#17), the output of the upper reference circuit goes low (\#18). This causes the output latch to tog-
gle, taking the Q output of the 'HC4538 to a low state (\#19), and completing the time-out cycle.

## RESET OPERATION

A low voltage applied to the Reset pin always forces the Q output of the 'HC4538 to a low state.
The timing diagram illustrates the case in which reset occurs (\#20) while $C_{x}$ is charging up toward the reference voltage of the upper reference circuit (\#21). When a reset occurs, the output of the reset latch goes low (\#22), turning on transistor M1. Thus $\mathrm{C}_{\mathrm{X}}$ is allowed to quickly charge up to $V_{C C}$ (\#23) to await the next trigger signal.

## RETRIGGER OPERATION

In the retriggerable mode, the 'HC4538 may be retriggered during timing out of the output pulse at any time after the trigger-control circuit flip-flop has been reset (\#24). Because the trigger-control circuit flip-flop resets shortly after $C_{X}$ has discharged to the reference voltage of the lower reference circuit (\#25), the minimum retrigger time, $\mathrm{t}_{\mathrm{rr}}$ is a function of internal propagation delays and the discharge time of $\mathrm{C}_{\mathrm{x}}$ :
$\mathrm{t}_{\mathrm{rr}}(\mathrm{ns}) \cong 72+\frac{\mathrm{V}_{\mathrm{CC}}(\text { volts }) \bullet \mathrm{C}_{\mathrm{X}}(\mathrm{pF})}{30.5}$, at room temperature

## POWER－DOWN CONSIDERATIONS

Large values of $C_{X}$ may cause problems when powering down the HC4538 because of the amount of energy stored in the capacitor．When a system containing this device is powered down，the capacitor may discharge from $V_{C C}$ through the input protection diodes at pin 2 or pin 14．Cur－ rent through the protection diodes must be limited to 30 mA ； therefore，the turn－off time of the $\mathrm{V}_{\mathrm{CC}}$ power supply must not be faster than $t=V_{C C}{ }^{\circ} \mathrm{C}_{x} /(30 \mathrm{~mA})$ ．For example，if $V_{C C}=5 \mathrm{~V}$ and $\mathrm{C}_{\mathrm{X}}=15 \mu \mathrm{~F}$ ，the $\mathrm{V}_{\mathrm{CC}}$ supply must turn off no faster than $t=(15 \mathrm{~V}) \bullet(15 \mu \mathrm{~F}) / 30 \mathrm{~mA}=2.5 \mathrm{~ms}$ ．This is usually not a problem because power supplies are heavily filtered and cannot discharge at this rate．
When a more rapid decrease of $V_{C C}$ to zero volts occurs， the HC4538 may sustain damage．To avoid this possibility， use an external clamping diode， $\mathrm{D}_{\mathrm{X}}$ ，connected from $\mathrm{V}_{\mathrm{CC}}$ to the $C_{X}$ pin．

## MM54HCT00/MM74HCT00 Quad 2 Input NAND Gate

## General Description

The MM54HCT00/MM74HCT00 are NAND gates fabricated using microCMOS Technology, 3.0 micron silicon gate N well CMOS, which provides the inherent benefits of CMOS-low quiescent power and wide power supply range. These devices are input and output characteristic and pinout compatible with standard DM54LS/74LS logic families. All inputs are protected from static discharge damage by internal diodes to $V_{C C}$ and ground.
MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These parts are also plug in replacements for LS-

TTL devices and can be used to reduce power consumption in existing designs.

## Features

- TTL, LS pin-out and threshold compatible
- Fast switching: $t_{\text {PLH }}, t_{\text {PHL }}=14 \mathrm{~ns}$ (typ)
- Low power: $10 \mu \mathrm{~W}$ at DC, 2.5 mW at $>5 \mathrm{MHz}$

■ High fan-out, 10 LS-TTL loads

## MM54HCT34/74HCT34 Non-Inverter

## General Description

The MM54HCT34/74HCT34 are logic functions fabricated using microCMOS Technology, 3.0 micron silicon gate N well CMOS, which provides the inherent benefits of CMOS low quiescent power and wide power supply range, but are input and output characteristic as well as pin-out compatible with standard DM54LS/74LS devices. The MM54HCT34/ MM74HCT34, triple buffered, inverting hex inverters, feature low power dissipation and fast switching times. All inputs are protected from static discharge by internal diodes to $V_{C C}$ and ground.
MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These parts are also plug in replacements for LSTTL devices and can be used to reduce power consumption in existing designs.

## Features

- TTL, LS pin-out and threshold compatible
- Fast switching: $T_{P L H}, T_{P H L}=8 \mathrm{~ns}$ (typ)
- Low power: $10 \mu \mathrm{~W}$ at DC, 2.5 mW at 5 MHz
- High fan-out: $\geq 10$ LS loads
- Inverting, triple buffered

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## General Description

The MM54HCT74／MM74HCT74 utilizes microCMOS Tech－ nology， 3.0 micron silicon gate N －well CMOS，to achieve operation speeds similar to the equivalent LS－TTL part．It possesses the high noise immunity and low power con－ sumption of standard CMOS integrated circuits，along with the ability to drive 10 LS－TTL loads．
This flip－flop has independent data，preset，clear，and clock inputs and $Q$ and $\bar{Q}$ outputs．The logic level present at the data input is transferred to the output during the positive－go－ ing transition of the clock pulse．Preset and clear are inde－ pendent of the clock and accomplished by a low level at the appropriate input．
The $54 \mathrm{HCT} / 74 \mathrm{HCT}$ logic family is functionally and pinout compatible with the standard 54LS／74LS logic family．All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground．

MM54HCT／MM74HCT devices are intended to interface be－ tween TTL and NMOS components and standard CMOS devices．These parts are also plug in replacements for LS－ TTL devices and can be used to reduce power consumption in existing designs．

## Features

－Typical propagation delay： 20 ns
■ Low quiescent current： $40 \mu \mathrm{~A}$ maximum（ 74 HCT series）
－Low input current： $1 \mu \mathrm{~A}$ maximum
－Fanout of 10 LS－TTL loads

## Truth Table

## MM54HCT76/MM74HCT76 MM54HCT112/MM74HCT112 Dual J-K Flip-Flops with Preset and Clear

## General Description

These flip-flops utilize silicon gate CMOS technology. They have input threshold and output drive similar to LS-TTL with the low standby power of CMOS.

These flip-flops have independent J, K, preset, clear and clock inputs and $Q$ and $\bar{Q}$ outputs. The flip-flops are edgetriggered and change state on the negative-going transition of the clock pulse. Preset and clear are independent of the clock and accomplished by a low logic level on the corresponding input.

All inputs to this device are protected from damage due to electrostatic discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

MM54HCT/MM74HCT devices are intended to interface TTL and NMOS components to CMOS components. When there is a LS-TTL equivalent, these parts can be used as plug-in replacements to reduce system power consumption in existing designs.

## Features

- Typical propagation delay: 20 ns

■ Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HCT series)

- Fanout of 10 LS-TTL loads

## Logic Diagram

## General Description

The MM54HCT107／MM74HCT107 utilize silicon gate CMOS technology．They have input threshold and output drive similar to LS－TTL with the low standby power of CMOS．

These flip－flops have independent $\mathrm{J}, \mathrm{K}$ ，clear and clock in－ puts and Q and $\overline{\mathrm{Q}}$ outputs．The flip－flops are edge－trig－ gered and change state on the negative－going transition of the clock pulse．Clear is independent of the clock and ac－ complished by a low level on the input．

All inputs to this device are protected from damage due to electrostatic discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground．

MM54HCT／MM74HCT devices are intended to interface TTL and NMOS components to CMOS components．When there is a LS－TTL equivalent，these parts can be used as plug－in replacements to reduce system power consump－ tion in existing designs．

## Features

－Typical propagation delay： 20 ns
－Low quiescent current $8 \mu \mathrm{~A}$ maximum（74HCT Series）
－Fanout of 10 LS－TTL loads

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## General Description

These high speed J-K FLIP-FLOPS utilize microCMOS Technology, 3.0 micron silicon gate N -well CMOS. They possess the low power consumption and high noise immunity of standard CMOS integrated circuits, along with the ability to drive 10 LS-TTL loads.
Each flip flop has independent $\mathrm{J}, \overline{\mathrm{K}}$, PRESET, CLEAR, and CLOCK inputs and Q and $\overline{\mathrm{Q}}$ outputs. These devices are edge sensitive to the clock input and change state on the positive going transition of the clock pulse. Clear and preset are independent of the clock and accomplished by a low logic level on the corresponding input.
The $54 \mathrm{HCT} / 74 \mathrm{HCT}$ logic family is functionally as well as pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These parts are also plug in replacements for LSTTL devices and can be used to reduce power consumption in existing designs.

## Features

- Typical propagation delay: 20 ns
- Low input current: $1 \mu \mathrm{~A}$ maximum

■ Low quiescent current: $40 \mu \mathrm{~A}$ maximum ( 74 HCT series)
■ Output drive capability: 10 LS-TTL loads

## MM54HCT138/MM74HCT138 3-to-8 Line Decoder

## General Description

This decoder utilizes microCMOS Technology, 3.0 micron silicon gate N -well CMOS, and are well suited to memory address decoding or data routing applications. Both circuits feature high noise immunity and low power consumption usually associated with CMOS circuitry, yet have speeds comparable to low power Schottky TTL logic.
The MM54HCT138/MM74HCT138 have 3 binary select inputs ( $A, B$, and $C$ ). If the device is enabled these inputs determine which one of the eight normally high outputs will go low. Two active low and one active high enables (G1, G2A and G2B) are provided to ease the cascading decoders.
The decoders' output can drive 10 low power Schottky TTL equivalent loads and are functionally and pin equivalent to the 54LS138/74LS138. All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These parts are also plug in replacements for LSTTL devices and can be used to reduce power consumption in existing designs.

## Features

- TTL Input Compatible
- Typical propagation delay: 20 ns
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HCT series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Fanout of 10 LS-TTL loads

## MM54HCT139/MM74HCT139 Dual

## 2-To-4 Line Decoder

## General Description

The MM54HCT139/MM74HCT139 is a high speed silicongate CMOS decoder that is well suited to memory address decoding or data routing applications. It possesses an input threshold and output drive similar to LS-TTL and the low standby of CMOS logic.
The device is comprised of two independent one-of-four decoders each with a single active low enable input (G1 or G2). Data on the select inputs (A1, B1 or A2, B2) cause one of the four normally high outputs to go low.
All inputs to the decoder are protected from damage due to electrostatic discharge by diodes to $V_{C C}$ and Ground. The
device is capable of driving 10 low power Schottky TTL equivalent loads.
The MM54HCT139/MM74HCT139 is functionally and pin equivalent to the 54LS139/74LS139 and can be used as a plug in replacement to reduce system power consumption in existing systems.

## Features

- Typical propagation delays: 20 ns
- Low quiescent current: $40 \mu \mathrm{~A}$ maximum ( 74 HCT series)
- Fanout of 10 LS-TTL loads

## MM54HCT：149／MM74HCT149 <br> 8 Line to 8 Line Priority Encoder

## General Description

This priority encoder is implemented in microCMOS Tech－ nology， 3.0 micron silicon gate N －well CMOS．It has the high noise immunity and low power consumption typical of CMOS circuits，as well as the speeds and output drive simi－ lar to LS－TTL．
This priority，encoder accepts 8 input request lines，$\overline{\mathrm{A} 17}$－ $\overline{\mathrm{RIO}}$ ，and outputs 8 lines，$\overline{\mathrm{RO7}}-\overline{\mathrm{ROO}}$ ．It is the logical combi－ nation of a＇148 8－3 line priority encoder driving a＇138 3－8 line decoder．Only one request output can be low at a time． The output that is low is dependent on the highest priority request input that is low．The order of priority is $\overline{\mathrm{RI}} 7$ highest and $\overline{R T O}$ lowest．Also provided is and enable input，$\overline{\text { RQE }}$ ， which when high forces all outputs high．A request output is also provided，$\overline{R Q P}$ ，which goes low when any $\overline{\mathrm{RI}}$ is active．
All inputs to this device are protected from damage due to electrostatic discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and Ground．

MM54HCT／MM74HCT devices are intended to interface be－ tween TTL and NMOS components and standard CMOS devices．These parts are also plug in replacements for LS－ TTL devices and can be used to reduce power consumption in existing designs．

## Features

－Typical propagation delay： 20 ns
－Low quiescent current： $80 \mu \mathrm{~A}$ maximum（ 74 HCT series）
－Low input current： $1 \mu \mathrm{~A}$ maximum
－Fanout of 10 LS－TTL loads
－Internal switched pull up resistors provided to reduce power consumption

## Simplified Logic Diagram

# National Semiconductor MM54HCT155/MM74HCT155 Dual 2-to-4 Line 

## General Description

The MM54HCT155/MM74HCT155 is a high speed silicon gate CMOS decoder/demultiplexer. It features dual 1-to-4 line demultiplexers with independent strobes and common binary address inputs. When both sections are enabled by the strobes, the common address inputs sequentially select and route associated input data to the appropriate output of each section. The individual strobes permit activating or inhibiting each of the 4 -bit sections as desired. Data applied to input C1 is inverted at its outputs and data applied to C 2 is true through its outputs. The inverter following the C 1 data input permits use as a 3 -to-8 line decoder, or 1-to-8 line demultiplexer, without gating.
All inputs to the decoder are protected from damage due to electrostatic discharge by diodes to $V_{C C}$ and ground. The device is capable of driving 10 low power Schottky TTL equivalent loads.

The MM54HCT155/MM74HCT155 is functionally and pin equivalent to the 54LS155/74LS155 and can be used as a plug-in replacement to reduce system power consumption in existing systems.

## Features

- Applications:

Dual 2-to-4 line decoder Dual 1-to-4 line demultiplexer 3 -to-8 line decoder 1-to-8 line demultiplexer

- Typical propagation delay: 22 ns

■ Low Quiescent current: $8 \mu \mathrm{~A}$ maximum ( 74 HC Series)

## Logic Diagram

## MM54HCT157/MM74HCT157 Quad 2-Input Multiplexer MM54HCT158/MM74HCT158 Quad 2-Input Multiplexer (Inverted Output)

## General Description

These high speed QUAD 2-to-1 LINE DATA SELECTOR/ MULTIPLEXERS utilize microCMOS Technology, 3.0 micron silicon gate N -well CMOS. They possess the high noise immunity and low power consumption of standard CMOS integrated circuits, as well as the ability to drive 10 LS-TTL loads.
These devices each consist of four 2-input digital multiplexers with common select and STROBE inputs. On the MM54HCT157/MM74HCT157, when the STROBE input is at logical " 0 " the four outputs assume the values as selected from the inputs. When the STROBE input is at a logical " 1 " the outputs assume logical " 0 ". The MM54HCT158/ MM74HCT158 operates in the same manner, except that its outputs are inverted. Select decoding is done internally resulting in a single select input only. If enabled, the select input determines whether the $A$ or $B$ inputs get routed to their corresponding $Y$ outputs.

The $54 \mathrm{HCT} / 74 \mathrm{HCT}$ logic family is functionally as well as pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 14 ns data to any output
- Power supply range: $5 \mathrm{~V} \pm 10 \%$
- Low power supply quiescent current: $80 \mu \mathrm{~A}$ maximum (74HCT series)
■ Fan-out of 10 LS-TTL loads
■ Low input current: $1 \mu \mathrm{~A}$ maximum
- Completely TTL compatible

|  |  | $\begin{aligned} & \mathrm{V}_{\mathrm{IN}}=\mathrm{V}_{\mathrm{IH}} \text { or } \mathrm{V}_{\mathrm{IL}} \\ & \left.\right\|_{\text {OUT }} \leq 4.0 \mathrm{~mA} \\ & \left.\right\|_{\text {OUT }} \leq 4.8 \mathrm{~mA} \\ & \hline \end{aligned}$ | $\begin{aligned} & 4.5 \mathrm{~V} \\ & 5.5 \mathrm{~V} \end{aligned}$ | $\begin{aligned} & 0.2 \\ & 0.2 \end{aligned}$ | $\begin{aligned} & 0.26 \\ & 0.26 \end{aligned}$ | $\begin{aligned} & 0.33 \\ & 0.33 \end{aligned}$ | $\begin{aligned} & 0.4 \\ & 0.4 \end{aligned}$ | $\begin{aligned} & v \\ & v \end{aligned}$ |
| IIN | Maximum Input Current | $\mathrm{V}_{\text {IN }}=\mathrm{V}_{\mathrm{CC}}$ or GND | 6.0V |  | $\pm 0.1$ | $\pm 1.0$ | $\pm 1.0$ | $\mu \mathrm{A}$ |
| lcc | Maximum Quiescent Supply Current | $\begin{aligned} & V_{I N}=V_{C C} \text { or } G N D \\ & l_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ | 6.0 V |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic " J " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HCT at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{\mathbb{H}}$ and $\mathrm{V}_{I L}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{\mathbb{H}}$ value at 5.5 V is 3.85 V .) The worst case leakage current (l|N , lcc, and loz) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

## General Description

The MM54HCT160／74HCT160，MM54HCT161／74HCT161， MM54HCT162／74HCT162，MM54HCT163／74HCT163 syn－ chronous presettable counters utilize microCMOS Tech－ nology， 3.0 micron silicon gate N －well CMOS，and internal look－ahead carry logic for use in high speed counting applications．They offer the high noise immunity and low power consumption inherent to CMOS with speeds similar to low power Schottky TTL．The＇HCT160 and the＇HCT162 are 4－bit decade counters，and the＇HCT161 and the＇HCT163 are 4－bit binary counters．All flip－flops are clocked simultaneously on the low to high to transition（positive edge）of the CLOCK input waveform．
These counters may be preset using the L．OAD input．Pre－ setting of all four flip－flops is synchronous to the rising edge of CLOCK．When LOAD is held low counting is disabled and the data on the $\mathrm{A}, \mathrm{B}, \mathrm{C}$ ，and D inputs is loaded into the counter on the rising edge of CLOCK．If the load input is taken high before the positive edge of CLOCK the count operation will be unaffected．
All of these counters may be cleared by utilizing the CLEAR input．The clear function on the MM54HCT162／ MM74HCT162 and MM54HCT163／MM74HCT163 counters are synchronous to the clock．That is，the counters are cleared on the positive edge of CLOCK while the clear input is held low．

The MM54HCT160／MM74HCT160 and MM54HCT161／ MM74HCT161 counters are cleared asynchronously．When the CLEAR is taken low the counter is cleared immediately regardless of the CLOCK．
Two active high enable inputs（ENP and ENT）and a RIP－ PLE CARRY（RC）output are provided to enable easy cas－ cading of counters．Both ENABLE inputs must be high to count．The ENT input also enables the RC output．When enabled，the RC outputs a positive pulse when the counter overflows．This pulse is approximately equal in duration to the high level portion of the $Q_{A}$ output．The RC output is fed to successive cascaded stages to facilitate easy implemen－ tation of N －bit counters．
These circuits are TTL input and output compatible and are plug in replaceable for＇LS16X Series counters．
All inputs are protected from damage due to static dis－ charge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground．

## Features

－Typical operating frequency： 40 MHz
－Typical propagation delay：clock to Q： 18 ns
－Low quiescent current： $80 \mu \mathrm{~A}$ maximum（ 74 HCT series）
－Low input current： $1 \mu \mathrm{~A}$ maximum
－Wide power supply range：2－6V
－TTL Input Compatible Inputs

## MM54HCT164/MM74HCT164 8-Bit Serial-in/Parallel-out Shift Register

## General Description

The MM54HCT164/MM74HCT164 utilize microCMOS Technology, 3.0 micron silicon gate N -well CMOS. It has the high noise immunity and low consumption of standard CMOS integrated circuits. It also offers speeds comparable to low power Schottky devices.
This 8-BIT SHIFT REGISTER has gated serial inputs and CLEAR. Each register bit is a D-type master/slave flip flop. Inputs A \& B permit complete control over the incoming data. A fow at either or both inputs inhibits entry of new data and resets the first flip flop to the low level at the next clock pulse. A high level on one input enables the other input which will then determine the state of the first flip flop. Data at the serial inputs may be changed while the clock is high or low, but only information meeting the setup and hold time requirements will be entered. Data is serially shifted in and out of the 8-BIT REGISTER during the positive going transition of the clock pulse. Clear is independent of the clock and accomplished by a low level at the CLEAR input.

The $54 \mathrm{HCT} / 74 \mathrm{HCT}$ logic family is functionally as well as pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.
MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These parts are also plug in replacements for LSTTL devices and can be used to reduce power consumption in existing designs.

## Features

- Typical propagation delay: 20 ns

E Low quiescent current: $40 \mu \mathrm{~A}$ maximum (74HCT series)

- Low input current: $1 \mu \mathrm{~A}$ maximum

■ Fanout of 10 LS-TTL loads

- TTL Input compatible

## Connection Diagram

## Truth Table

| Inputs |  |  |  |  | Outputs |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Clear | Clock | $\mathbf{A}$ | $\mathbf{B}$ | $\mathbf{Q}_{\mathbf{A}}$ | $\mathbf{Q}_{\mathbf{B}}$ | $\ldots$ | $\mathbf{Q}_{\mathbf{H}}$ |  |
| L | X | X | X | L | L |  | L |  |
| H | L | X | X | $\mathrm{Q}_{\mathrm{AO}}$ | $\mathrm{Q}_{\mathrm{BO}}$ |  | $\mathbf{Q}_{\mathrm{HO}}$ |  |
| H | $\uparrow$ | H | H | H | $\mathrm{Q}_{\mathrm{An}}$ |  | $\mathrm{Q}_{\mathrm{Gn}}$ |  |
| H | $\uparrow$ | L | X | L | $\mathbf{Q}_{\mathrm{An}}$ |  | $\mathbf{Q}_{\mathrm{Gn}}$ |  |
| H | $\uparrow$ | X | L | L | $\mathrm{Q}_{\mathrm{An}}$ |  | $\mathbf{Q}_{\mathrm{Gn}}$ |  |

$\mathrm{H}=$ High Level (steady state), L = Low Level (steady state)
$X=$ Irrelevant (any input, including transitions)
$\uparrow=$ Transition from low to high level.
$Q_{A O}, Q_{B O}, Q_{H O}=$ the level of $Q_{A}, Q_{B}$, or $Q_{H}$, respectively, before the indicated steady state input conditions were established.
$\mathrm{Q}_{\mathrm{An}}, \mathrm{Q}_{\mathrm{Gn}}=$ The level of $\mathrm{Q}_{\mathrm{A}}$, or $\mathrm{Q}_{\mathrm{G}}$ before the most recent $\uparrow$ transition of the clock; indicated a one-bit shift.

## MM54HCT166/MM74HCT166 8-Bit Serial or Parallel Input/Serial Output Shift Register with Reset

## General Description

These shift registers utilize microCMOS technology, 3.0 micron silicon gate N -well CMOS. The MM54HCT166/ MM74HCT166 are 8-bit shift registers with an output from the last stage. Data may be loaded into the register in either parallel or serial form.
When the shift/load input is low, the data is loaded asynchronously in parallel. When the shift/load input is high, the data is loaded serially on the rising edge of either Clock 1 or Clock 2 (see the Function Table). Reset is asynchronous and active low.
The 2-Input NOR clock may be used either by combining two independent clock sources or by designating one of the clock inputs to act as a clock inhibit.
These devices are input and output characteristic and pinout compatible with standard 54LS/74LS logic famllies. $54 \mathrm{HCT} / 74 \mathrm{HCT}$ devices are intended to interface be-
tween TTL and NMOS components and standard CMOS devices. These parts are also plug-in replacements for LS.TTL devices and can be used to reduce power consumption in existing designs.
All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{Cc}}$ and ground.

## Features

- Wide power supply range: 2V-6V

■ Low input current: $1 \mu \mathrm{~A}$ maximum

- Low quiescent current: $80 \mu \mathrm{~A} \max$ ( 74 HCT series)

준 Fanout of 10 LS-TTL loads

- TTL-compatible inputs

# MM54HCT169/MM74HCT169 4-Bit Up/Down Synchronous Binary Counter 

## General Description

These counters are implemented using an advanced 3.0 micron silicon gate N -well microCMOS process to achieve high performance. These devices retain the low power of CMOS logic while offering the high speed operation and large output drive typically associated with bipolar circuits. This device is input compatible with the 54LS/74LS and other TTL output compatible circuits, and may be used as a lower power direct replacement for the LS equivalent device.
These counters are incremented or decremented on the rising edge of the CLK, clock, input if ENT and ENP are held low. The counters increment when the U/ $\bar{D}$ input is at a logic " 1 ", and will decrement when U/D is low. The ENT input is fed forward to enable the carry output. $\overline{\mathrm{RCO}}$, ripple carry output, once enabled, will produce a low level pulse while the count is 0 (down count mode) or when the count is all is (up mode).

These counters are presettable, that is, they may be loaded when $\overline{\text { LOAD }}$ is taken low and a rising edge appears on the CLK input.

The MM54HCT169/MM74HCT169 are functional, speed and pin equivalent to the equivalent LS-TTL circuit, and may be used as a direct replacement for the equivalent LS-TTL IC. Its inputs are protected from damage due to electrostatic discharge by diodes from $V_{C C}$ to ground.

## Features

Wide power supply range: 4.5 V to 5.5 V

- Guaranteed TTL compatible input logic levels: 2.0 V and 0.8 V
- Wide operating frequency range: 30 MHz
- High output current drive: 6.0 mA min

## MM54HCT174/MM74HCT174 Hex D Flip-Flops with Clear

## General Description

The MM54HCT174/MM74HCT174 utilize 3.0 micron N-well microCMOS technology. They have input threshold and output drive similar to LS-TTL with the low standby power of CMOS.

These positive edge-triggered flip-flops have a common clock and clear and independent Q outputs. Data on a D input, having the specified set-up and hold time, is transferred to the corresponding Q output on the positive-going transition of the clock pulse. The asynchronous clear forces all outputs low when it is low.
All inputs to this device are protected from damage due to electrostatic discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

MM54HCT/MM74HCT devices are intended to interface TTL and NMOS components to CMOS components. When there is a LS-TTL equivalent, these parts can be used as plug-in replacements to reduce system power consumption in existing designs.

## Features

- Typical propagation delay: 20 ns
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HCT series)
- Fanout of 10 LS-TTL loads

## Connection Diagram

Dual-In-Line Package

Truth Table (Each Flip-Flop)

| Inputs |  |  | Outputs |
| :---: | :---: | :---: | :---: |
| Clear | Clock | D | Q |
| L | X | X | L |
| H | I | H | H |
| H | I | L | L |
| H | L | X | Q0 |

$\mathrm{H}=$ high level (steady-state)
$\mathrm{L}=$ low level (steady-state)
$X=$ don't care
$t=$ transition from low to high level
$\mathbf{Q O}=$ the level of $\mathbf{Q}$ before the indicated steady-state input conditions were established.

microCMOS

## MM54HCT191/MM74HCT191 Synchronous Binary Up/Down Counters with Mode Control

## General Description

These high speed synchronous counters utilize microCMOS technology, 3.0 micron silicon gate N -well CMOS. They possess the high noise immunity and low power consumption of CMOS technology, along with the speeds of low power Schottky TTL.

These circuits are synchronous, reversible, up/down counters. The MM54HCT191/MM74HCT191 are 4-bit binary counters.
Synchronous operation is provided by having all flip-flops clocked simultaneously so that the outputs change simultaneously when so instructed by the steering logic. This mode of operation eliminates the output counting spikes normally associated with asynchronous (ripple clock) counters.
The outputs of the four master-slave flip-flops are triggered on a low-to-high level transition of the clock input, if the enable input is low. A high at the enable input inhibits counting. Level changes at either the enable input or the down/up input should be made only when the clock input is high. The direction of the count is determined by the level of the down/up input. When low, the counter counts up and when high, it counts down.
These counters are fully programmable; that is, the outputs may be preset to either level by placing a low on the load input and entering the desired data at the data inputs. The output will change independent of the level of the clock input. This feature allows the counters to be used as divide by $N$ dividers by simply modifying the count length with the preset inputs.

Two outputs have been made available to perform the cascading function; ripple clock and maximum/minimum count. The latter output produces a high level output pulse with a duration approximately equal to one complete cycle of the clock when the counter overflows or underflows. The ripple clock output produces a low level output pulse equal in width to the low level portion of the clock input when an overflow or underflow condition exists. The counters can be easily cascaded by feeding the ripple clock output to the enable input of the succeeding counter if parallel clocking is used, or to the clock input if parallel enabling is used. The maximum/minimum count output can be used to accomplish look-ahead for high speed operation.
MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These parts are also plug-in replacements for LS-TTL devices and can be used to reduce power consumption in existing designs.

## Features

- Typical propagation delay, clock to output: 24 ns
- Typical operating frequency: 50 MHz
- Wide power supply range: $2 \mathrm{~V}-6 \mathrm{~V}$
- Low quiescent supply current: $80 \mu \mathrm{~A}$ maximum ( 74 HCT series)
- Low input current: $1 \mu \mathrm{~A}$ maximum
- TTL compatible inputs

HCT191 Binary Counters

## MM54HCT193／MM74HCT193 Synchronous Binary Up／Down Counters

These high speed synchronous counters utilize microCMOS technology， 3.0 micron silicon gate N －well CMOS to achieve the high noise immunity and low power consumption of CMOS technology，along with the speeds of low power Schottky TTL．The MM54HCT193／MM74HCT193 is a binary counter having two separate clock inputs，an UP COUNT in－ put and a DOWN COUNT input．All outputs of the flip－flops are simultaneously triggered on the low－to－high transition of either clock while the other input is held high．The direc－ tion of counting is determined by which input is clocked．
This device has TTL compatible inputs．It can drive 15 LS－TTL loads．
This counter may be preset by entering the desired data on the DATA A，DATA B，DATA C，and DATA D inputs．When the LOAD input is taken low，the data is loaded independ－ ently of either clock input．This feature allows the counter to be used as a divide－by－n counter by modifying the count length with the preset inputs．
In addition，the HCT191 can also be cleared．This is ac－ complished by inputting a high on the CLEAR input．All 4 internal stages are set to a low level independently of either COUNT input．

Both a BORROW and CARRY output are provided to enable cascading of both up and down counting func－ tions．The BORROW output produces a negative－going pulse when the counter underflows and the CARRY out－ puts a pulse when the counter overflows．The counter can be cascaded by connecting the CARRY and BORROW out－ puts of one device to the COUNT UP and COUNT DOWN inputs，respectively，of the next device．

All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground．

## Features

－Typical propagation delay，clock to output： 18 ns
－Typical operating frequency： 27 MHz
－Wide power supply range： $2 \mathrm{~V}-6 \mathrm{~V}$
－Low quiescent supply current： $80 \mu \mathrm{~A}$ maximum（ 74 HCT series）
－Low input current： $1 \mu \mathrm{~A}$ maximum
－TTL compatible inputs

Logic Diagram

MM54HCT193/MM74HCT193 Synchronous 4-Bit Up/Down Binary Counter

# MM54HCT240/MM74HCT240 Inverting Octal TRI-STATE ${ }^{\circledR}$ Buffer MM54HCT241/MM74HCT241 Octal TRI-STATE Buffer MM54HCT244/MM74HCT244 Octal TRI-STATE Buffer 

## General Description

These TRI-STATE buffers utilize microCMOS Technology, 3.0 micron silicon gate N -well CMOS, and are general purpose high speed inverting and non-inverting buffers. They possess high drive current outputs which enable high speed operation even when driving large bus capacitances. These circuits achieve speeds comparable to low power Schottky devices, while retaining the low power consumption of CMOS. All three devices are TTL input compatible and have a fanout of $15 \mathrm{LS}-\mathrm{TTL}$ equivalent inputs.
MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These parts are also plug in replacements for LSTTL devices and can be used to reduce power consumption in existing designs.
The MM54HCT240/MM74HCT240 is an inverting buffer and the MM54HCT244/MM74HCT244 is non-inverting buff-
er. Each device has two active low enables (1G and 2G), and each enable independently controls 4 buffers. MM54HCT241/MM74HCT241 is also a non-inverting buffer like the 244 except that the 241 has one active high enable, each again controlling 4 buffers.
All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and Ground.

## Features

- TTL input compatible
- Typical propagation delay: 12 ns
- TRI-STATE outputs for connection to system buses
- Low quiescent current: $80 \mu \mathrm{~A}$
- Output current: 6 mA

## MM54HCT245/MM74HCT245 <br> Octal TRI-STATE ${ }^{\circledR}$ Transceiver

## General Description

This TRI-STATE bi-directional buffer utilizes microCMOS Technology, 3.0 micron silicon gate N-well CMOS, and is intended for two-way asynchronous communication between data buses. It has high drive current outputs which enable high speed operation even when driving large bus capacitances. This circuit possess the low power consumption of CMOS circuitry, yet have speeds comparable to low power Schottky TTL circuits.
This device is TLL input compatible and can drive up to 15 LS-TTL loads, and all inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.
MM54HCT245/MM74HCT245 has one active low enable input ( $\bar{G}$ ), and a direction control (DIR). When the DIR input is high, data flows from the $A$ inputs to the $B$ outputs. When DIR is low, data flows from $B$ to $A$.
MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS

## Connection Diagram

## Logic Diagram

National Semiconductor

## MM54HCT257/MM74HCT257 <br> Quad 2-Channel TRI-STATE ${ }^{\circledR}$ Multiplexer

## General Description

This QUAD 2-TO-1 LINE DATA SELECTOR/MULTIPLEXER utilizes microCMOS Technology, 3.0 micron silicon gate N well CMOS. Along with the high noise immunity and low power dissipation of standard CMOS integrated circuits, it possesses the ability to drive LS-TTL loads. The large output drive capability coupled with the TRI-STATE feature make this device ideal for interfacing with bus lines in a bus organized system. When the OUTPUT CONTROL input line is taken high, the outputs of all four multiplexers are sent into a high impedance state. When the OUTPUT CONTROL line is low, the SELECT input chooses whether the A or B input is used.

The $54 \mathrm{HCT} / 74 \mathrm{HCT}$ logic family is speed, function, and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

■ Typical propagation delay: 12 ns

- Wide power supply range: $2 \mathrm{~V}-6 \mathrm{~V}$

■ Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HCT series)
m TRI-STATE outputs for connection to system buses.

- Completely TTL compatible

| ${ }^{\text {ICC }}$ | Maximum Quiescent Supply Current | $\begin{aligned} & V_{\text {IN }}=V_{C C} \text { or GND } \\ & I_{\text {OUT }}=0 \mu \mathrm{~A} \end{aligned}$ |  | 8.0 | 80 | 160 | $\mu \mathrm{A}$ |

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.
Note 2: Unless otherwise specified all voltages are referenced to ground.
Note 3: Power Dissipation temperature derating - plastic " N " package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $65^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$; ceramic "J" package: $-12 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ from $100^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$.
Note 4: For a power supply of $5 \mathrm{~V} \pm 10 \%$ the worst case output voltages ( $\mathrm{V}_{\mathrm{OH}}$, and $\mathrm{V}_{\mathrm{OL}}$ ) occur for HC at 4.5 V . Thus the 4.5 V values should be used when designing with this supply. Worst case $\mathrm{V}_{I H}$ and $\mathrm{V}_{\mathbb{I}}$ occur at $\mathrm{V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ and 4.5 V respectively. (The $\mathrm{V}_{I H}$ value at 5.5 V is 3.85 V .) The worst case leakage current (liN , lcc , and $\mathrm{l}_{\mathrm{OZ}}$ ) occur for CMOS at the higher voltage and so the 6.0 V values should be used.

AC Electrical Characteristics $\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}, \mathrm{C}_{\mathrm{L}}=45 \mathrm{pF}, \mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$ (unless otherwise noted.)

## MM54HCT273/MM74HCT273 Octal D Flip.Flop with Clear

## General Description

The MM54HCT273/MM74HCT273 utilizes 3.0 micron N -well microCMOS technology. It has input threshold and output drive similar to LS-TTL with the low standby power of CMOS.
These positive edge-triggered flip-flops have a common clock and clear and independent Q outputs. Data on a Dinput, having the specified set-up and hold time is transferred to the corresponding Q output on the positive-going transition of the clock pulse. The asynchronous clear forces all outputs low when it is low.
All inputs to this device are protected from damage due to electrostatic discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

MM54HCT/MM74HCT devices are intended to interface TTL and NMOS components to CMOS components. These parts can be used as plug-in replacements to reduce system power consumption in existing designs.

## Features

Typical propagation delay: 20 ns

- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HCT series)
- Fanout of 10 LS-TTL loads

## Connection Diagram

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+I_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+I_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HCT299/MM74HCT299 8-Bit TRI-STATE ${ }^{\circledR}$ Universal Shift Register

## General Description

This 8-bit TRI-STATE shift/storage register utilizes microCMOS technology, 3.0 micron silicon gate N -well CMOS. Along with the low power consumption and high noise immunity of standard CMOS integrated circuits, it has the ability to drive 15 LS-TTL loads. This circuit also features operating speeds comparable to the equivalent low power Schottky device.

The MM54HCT299/MM74HCT299 is TTL input compatible. It features multiplexed inputs/outputs to achieve full 8 -bit data handling in a single 20-pin package. Due to the large output drive capability and TRI-STATE feature, this device is ideally suited for interfacing with bus lines in a bus oriented system.

Two function select inputs and two output control inputs are used to choose the mude of operation as listed in the function table. Synchronous parallel loading is accomplished by taking both function select lines, S 0 and S1, high. This places the TRI-STATE outputs in a high impedance state, which permits data applied to the input/output lines
to be clocked into the register. Reading out of the register can be done while the outputs are enabled in any mode. A direct overriding CLEAR input is provided to clear the register whether the outputs are enabled or disabled.

The MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These devices are also plug-in replacements for LS-TTL devices and can be used to reduce power consumption in existing designs.

All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

## Features

- TRI-STATEable I/O
( Output drive capability: 15 LS-TTL loads
- Cascadable for $n$-bit word lengths

■ Clock-independent clear

## Connection Diagram

Dual-In-Line Package

## MM54HCT323/MM74HCT323

## 8-Bit TRI-STATE ${ }^{\oplus}$ Universal Shift Register

## General Description

This 8-bit TRI-STATE shift/storage register utilizes microCMOS technology, 3.0 micron silicon gate N -well CMOS. Along with the low power consumption and high noise immunity of standard CMOS integrated circuits, it has the ability to drive 15 LS-TTL loads. This circuit also features operating speeds comparable to the equivalent low power Schottky device.
The MM54HCT323/MM74HCT323 is TTL input compatible. It features multiplexed inputs/outputs to achieve full 8 -bit data handling in a single 20 -pin package. Due to the large output drive capability and JRI-STATE feature, this device is ideally suited for interfacing with bus lines in a bus oriented system.
Two function select inputs and two output control inputs are used to choose the mode of operation as listed in the function table. Synchronous parallel loading is accomplished by taking both function select lines, S 0 and S 1 , high. This places the TRI-STATE outputs in a high impedance state, which permits data applied to the input/output lines
to be clocked into the register. Reading out of the register can be done while the outputs are enabled in any mode. A synchronous CLEAR input is provided to clear the register whether the outputs are enabled or disabled.

The MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These devices are also plug-in replacements for LS-TTL devices and can be used to reduce power consumption in existing designs.
All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- TRI-STATEable I/O
m Output drive capability: 15 LS-TTL loads
- Cascadable for $n$-bit word lengths
- Synchronous clear

## MM54HCT373/MM74HCT373 TRI-STATE® Octal D-Type Latch MM54HCT374/MM74HCT374 TRI-STATE Octal D-Type Flip-Flop

what signals are present at.the other inputs and the state of the storage elements.
MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These parts are also plug in replacements for LSTTL devices and can be used to reduce power consumption in existing designs.

## Features

- TTL input characteristic compatible
- Typical propagation delay: 20 ns
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum
- Compatible with bus-oriented systems
(m) Output drive capability: 15 LS-TTL loads and the state of the storage elements.
The MM54HCT374/MM74HCT374 are positive edge triggered flip-flops. Data at the $D$ inputs, meeting the setup and hold time requirements, are transferred to the Q outputs on positive going transitions of the CLOCK (CK) input. When a high logic level is applied to the OUTPUT CONTROL (OC) input, all outputs go to a high impedance state, regardless of

MM54HCT374/MM74HCT374

## MM54HCT521/MM74HCT521 <br> 8-Bit Magnitude Comparator (Equality Detector)

## General Description

This equality detector utilizes microCMOS Technology, 3.0 micron silicon gate N -well CMOS to compare bit for bit two 8 -bit words and indicate whether or not they are equal. The $\overline{\mathrm{P}=\mathrm{Q}}$ output indicates equality when it is low. A single active low enable is provided to facilitate cascading of several packages and enable comparison of words greater than 8 bits.
This device is useful in memory block decoding applications, where memory block enable signals must be generated from computer address information.
The comparator combines the low power consumption of CMOS, but inputs are compatible with TTL logic levels, and the output can drive 10 low power Schottky equivalent loads.

MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These parts are also plug in replacements for LSTTL devices and can be used to reduce power consumption in existing designs.
All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- TTL Input Compatible
- Typical propagation delay: 20 ns

■ Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HCT series)

- Large output current: 4 mA

# MM54HCT534／MM74HCT534 TRI－STATE Octal D－Type Flip－Flop 

TRI－STATE ${ }^{\circledR}$ Octal D－Type Latch

## General Description

The MM54HCT533／MM74HCT533 Octal D－TYPE LATCH－ ES and MM54HCT534／MM74HCT534 Octal D－TYPE FLIP FLOPS utilize microCMOS Technology， 3.0 micron silicon gate N －well CMOS，which provides the inherent benefits of low power consumption and wide power supply range，but are LS－TTL input and output characteristic \＆pinout compat－ ible．The TRI－STATE outputs are capable of driving 15 LS TTL loads．All inputs are protected from damage due to static discharge by internal diodes to $V_{C C}$ and ground．
When the MM54HCT533／MM74HCT533 LATCH ENABLE input is high，the $\bar{Q}$ outputs will follow the $D$ inputs．When the LATCH ENABLE goes low，data at the D inputs will be retained at the outputs until LATCH ENABLE returns high again．When a high logic level is applied to the OUTPUT CONTROL input，all outputs go to a high impedance state， regardless of what signals are present at the other inputs and the state of the storage elements．
The MM54HCT534／MM74HCT534 are positive edge trig－ gered flip－flops．Data at the D inputs，meeting the setup and hold time requirements，are transferred to the $\overline{\mathrm{Q}}$ outputs on
positive going transitions of the CLOCK（CK）input．When a high logic level is applied to the OUTPUT CONTROL（OC） input，all outputs go to a high impedance state，regardless of what signals are present at the other inputs and the state of the storage elements．
MM54HCT／MM74HCT devices are intended to interface be－ tween TTL and NMOS components and standard CMOS devices．These parts are also plug in replacements for LS－ TTL devices and can be used to reduce power consumption in existing designs．

## Features

－TTL input characteristic compatible
－Typical propagation delay： 18 ns
Low input current： $1 \mu \mathrm{~A}$ maximum
a Low quiescent current： $80 \mu \mathrm{~A}$ maximum
－Compatible with bus－oriented systems
－Output drive capability： 15 LS－TTL loads

## MM54HCT540/MM74HCT540 Inverting Octal TRI-STATE® Buffer MM54HCT541/MM74HCT541 Octal TRI-STATE Buffer

## General Description

These TRI-STATE buffers utilize microCMOS Technology, 3.0 micron silicon gate N -well CMOS, and are general purpose high speed inverting and non-inverting buffers. They possess high drive current outputs which enable high speed operation even when driving large bus capacitances. These circuits achieve speeds comparable to low power Schottky devices, while retaining the low power consumption of CMOS. Both devices are TTL input compatible and have a fanout of 15 LS-TTL equivalent inputs.
MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These parts are also plug in replacements for LSTTL devices and can be used to reduce power consumption in existing designs.
The MM54HCT540/MM74HCT540 is an. inverting buffer and the MM54HCT541/MM74HCT541 is a non-inverting buffer. The TRI-STATE control gate operates as a two-input

NOR such that if either $\overline{\mathrm{G} 1}$ or $\overline{\mathrm{G} 2}$ are high, all eight outputs are in the high-impedance state.
In order to enhance PC board layout, the 'HCT540 and 'HCT541 offers a pinout having inputs and outputs on opposite sides of the package. All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- TTL input compatible

Typical propagation delay: 12 ns

- TRI-STATE outputs for connection to system buses
- Low quiescent current: $80 \mu \mathrm{~A}$
- Output current: 6 mA

Note 5: $C_{P D}$ determines the no load dynamic power consumption, $P_{D}=C_{P D} V_{C C}{ }^{2} f+I_{C C} V_{C C}$, and the no load dynamic current consumption, $I_{S}=C_{P D} V_{C C} f+I_{C C}$.
Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## General Description

This octal transcieiver utilizes microCMOS technology, 3.0 micron silicon gate N -well CMOS, and is intended for two-way asynchronous communication between data buses. These devices possess the low power consumption of CMOS circuitry, yet have speeds comparable to low power Schottky TTL circuits. They are also input and output compatible with LS-TTL, and can drive up to 15 LS-TTL loads. All inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.
The HCT543 contains two sets of D-type latches for temporary storage of data flowing in either direction. Separate latch enable and output enable inputs are provided for each register to permit independent control of inputting and outputting in either direction of data flow.
For data flow from $A$ to $B$, for example, the $A$-to- $B$ enable ( $\overline{E A B}$ ) input must be 'low' in order to enter data from $A 0-A 7$ or take data from $\mathrm{B} 0-\mathrm{B} 7$, as indicated in the $/ / \mathrm{O}$ Control Table. With $\overline{\mathrm{EAB}}$ low, a low signal on A -to. B latch enable ( $\overline{\mathrm{LEAB}}$ ) input makes the $\mathrm{A}-\mathrm{to}$-B latches transparent; a subsequent low-to-high transition of the $\overline{\text { LEAB }}$ signal puts the A latches in the storage mode and their outputs no longer change with the $A$ inputs. With $\overline{E A B}$ and $\overline{O E A B}$ both low, the TRI-STATE ${ }^{\oplus}$ B output buffers are active and reflect the data present at the output of the $A$ latches. Control of data flow from $B$ to $A$ is similar, but uses the $\overline{E B A}, \overline{\angle E B A}$ and $\overline{O E B A}$ inputs.

## Features

- TTL input compatible
- Octal TRI-STATE outputs for $\mu \mathrm{P}$ bus applications
- Output drive capability: 15 LS-TTL loads

国 Large output current: 6 mA

- Back-to-back registers for storage
- Separate controls for data flow in each direction

## I/O Control Table

| Inputs |  |  | Latch Status | Output Buffers |
| :---: | :---: | :---: | :---: | :---: |

Dual-In-Line Package

# MM54HCT550/MM74HCT550 Octal Registered Transceiver with Status Flags 

## General Description

This octal transceiver utilizes microCMOS technology, 3.0 micron silicon gate N -well CMOS, and is intended for two-way asynchronous communication between data buses. These devices possess the low power consumption of CMOS circuitry, yet have speeds comparable to low power Schottky TTL circuits. They are also input and output compatible with LS-TTL, and can drive up to 15 LS-TTL loads. All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

The MM54HCT550/MM74HCT550 contain two 8 -bit registers for temporary storage of data flowing in either direction. Each register has its own clock pulse and clock enable inputs, as well as a flag flip-flop that is set automatically as the register is loaded. Each flag flip-flop is provided with a clear input, and each register has a separate output enable control for its TRI-STATE ${ }^{\mathbb{Q}}$ buffers. The separate clocks, flags and enables provide considerable flexibility as I/O ports for demand-response data transfer.
Data applied to the A inputs is entered and stored on the rising edge of the $A$ clock pulse (CPA), provided that the $A$ clock enable ( $\overline{\mathrm{CEA}}$ ) is low; simultaneously, the status flip. flop is set and the A-to-B flag (FAB) output goes high. Data
thus entered from the $A$ inputs is present at the inputs to the $B$ output buffers, but appears only on the $B / / O$ pins when the $B$ output enable $(\overline{\mathrm{OEB}})$ signal is made low. After the B output data is assimilated, the receiving system clears the A.to.B flag flip-flop by applying a low-to-high transition to the CFAB input. Optionally, the $\overline{O E A}$ and CFAB pins can be tied together and operated by one function from the receiving system.

Data flow from B-to-A proceeds in the same manner described for $A$-to- $B$ flow. Inputs $\overline{C E B}$ and $C P B$ enter the $B$ input data and set the B-to-A flag (FBA) output high. A low signal on OEA enables the A output buffers and a low-tohigh transition on CFBA clears the FBA flag.

## Features

- TTL compatible inputs
- Output drive: 15 LS-TTL loads
- Large output current: 6 mA
- Back-to-back registers for storage
- Register status flag flip.flops
- Separate edge-detecting clears for flags

MM54HCT551/MM74HCT551 Octal Registered Inverting Transceiver with Status Flags

## General Description

This octal transceiver utilizes microCMOS technology, 3.0 micron silicon gate N -well CMOS, and is intended for two-way asynchronous communication between data buses. These devices possess the low power consumption of CMOS circuitry, yet have speeds comparable to low power Schottky TTL circuits. They are also input and output compatible with LS-TTL, and can drive up to 15 LS-TTL loads. All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.
The MM54HCT551/MM74HCT551 contain two 8 -bit registers for temporary storage of data flowing in either direction. Each register has its own clock pulse and clock enable inputs, as well as a flag flip-flop that is set automatically as the register is loaded. Each flag flip.flop is provided with a clear input, and each register has a separate output enable control for its TRI-STATE ${ }^{\text {© }}$ buffers. The separate clocks, flags and enables provide considerable flexibility as $1 / O$ ports for demand-response data transfer.
Data applied to the $A$ inputs is entered and stored on the rising edge of the $A$ clock pulse (CPA), provided that the $A$ clock enable ( $\overline{C E A}$ ) is low; simultaneously, the status flipflop is set and the A-to-B flag (FAB) output goes high. Data
thus entered from the $A$ inputs is present at the inputs to the $B$ output buffers, but appears only on the $B / / O$ pins when the $B$ output enable $(\overline{\mathrm{OEB}})$ signal is made low. After the $B$ output data is assimilated, the receiving system clears the A-to-B flag flip-flop by applying a low-to-high transition to the CFAB input. Optionally, the $\overline{O E A}$ and CFAB pins can be tied together and operated by one function from the receiving system.
Data flow from B-to-A proceeds in the same manner described for $A$-to-B flow. Inputs $\overline{\mathrm{CEB}}$ and $C P B$ enter the $B$ input data and set the B-to-A flag (FBA) output high. A low signal on OEA enables the A output buffers and a low-tohigh transition on CFBA clears the FBA flag.

## Features

- Inverting outputs
- TTL compatible inputs
- Output drive: 15 LS-TTL loads
- Large output current: 6 mA
- Back-to-back registers for storage
- Register status flag flip-flops
- Separate edge-detecting clears for flags

## Logic Diagram ${ }^{\prime}$

## Connection Diagram

Dual-In-Line Package

## MM54HCT563/MM74HCT563 TRI-STATE ${ }^{\circledR}$ Octal D-Type Latch with Inverted Outputs

## General Description

These high speed OCTAL D-TYPE LATCHES utilize microCMOS Technology, 3.0 micron silicon gate N -well CMOS. They possess the high noise immunity and low power consumption of standard CMOS integrated circuits, as well as the ability to drive 15 LS-TTL loads. Due to the large output drive capability and the TRI-STATE feature, these devices are ideally suited for interfacing with bus lines in a bus organized system.
When the LATCH ENABLE (LE) input is high, the Q outputs will follow the inversion of the D inputs. When the LATCH ENABLE goes low, data at the D inputs will be retained at the outputs until LATCH ENABLE returns high again. When a high logic level is applied to the OUTPUT CONTROL input, all outputs go to a high impedance state, regardless of what signals are present at the other inputs and the state of the storage elements.

The $54 \mathrm{HCT} / 74 \mathrm{HCT}$ logic family is speed, function and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 13 ns
m Low input current: $1 \mu \mathrm{~A}$ maximum
■ Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 series)
- Compatible with bus-oriented systems

■ Output drive capability: 15 LS-TTL loads

- TTL input characteristic compatible

MM54HCT564/MM74HCT564
TRI-STATE ${ }^{\circledR}$ Octal D-Type Flip-Flop with Inverted Outputs

## General Description

These octal D-type flip-flops utilize microCMOS Technology, 3.0 micron silicon gate N -well CMOS. They possess the high noise immunity and low power consumption of standard CMOS integrated circuits as well as the ability to drive 15 LS-TTL loads. Due to the large output drive capability and the TRI-STATE feature, these devices are ideally suited for interfacing with bus lines in a bus organized system.
These devices are positive edge triggered flip-flops. Data at the $D$ inputs, meeting the set-up and hold time requirements, are transferred to the $\bar{Q}$ outputs on positive going transitions of the CLOCK (CK) input. When a high logic level is applied to the OUTPUT CONTROL (OC) input, all outputs go to a high impedance state, regardless of what signals are present at the other inputs and the state of the storage elements.

The $54 \mathrm{HCT} / 74 \mathrm{HCT}$ logic family is speed, function, and pinout compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 15 ns
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 Series)
- Compatible with bus-oriented systems
© Output drive capability: 15 LS-TTL loads
- TTL input characteristic compatible

Note 6: Refer to back of this section for Typical MM54/74HC AC Switching Waveforms and Test Circuits.

## MM54HCT573/MM74HCT573 <br> TRI-STATE ${ }^{\circledR}$ Octal D-Type Latch

## General Description

These high speed octal D-type latches utilize microCMOS Technology, 3.0 micron silicon gate N -well CMOS. They possess the high noise immunity and low power consumption of standard CMOS integrated circuits, as well as the ability to drive 15 LS-TTL loads. Due to the large output drive capability and the TRI-STATE feature, these devices are ideally suited for interfacing with bus lines in a bus organized system.
When the LATCH ENABLE(LE) input is high, the Q outputs will follow the D inputs. When the LATCH ENABLE goes low, data at the D inputs will be retained at the outputs until LATCH ENABLE returns high again. When a high logic level is applied to the OUTPUT CONTROL input, all outputs go to a high impedance state, regardless of what signals are present at the other inputs and the state of the storage elements.
MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS
devices. These parts are also plug in replacements for LSTTL devices and can be used to reduce power consumption in existing designs.
All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and Ground.

## Features

- TTL input characteristic compatible
- Typical propagation delay: 14 ns
- Low input current: $1 \mu \mathrm{~A}$ maximum
- Low quiescent current: $80 \mu \mathrm{~A}$ maximum
- Compatible with bus-oriented systems
- Output drive capability: 15 LS-TTL loads

MM54HCT574/MM74HCT574
TRI-STATE ${ }^{\circledR}$ Octal D-Type Flip-Flop

## General Description

These high speed octal D-type flip-flops utilize microCMOS Technology, 3.0 micron silicon gate N -well CMOS. They possess the high noise immunity and low power consumption of standard CMOS integrated circuits, as well as the ability to drive 15 LS-TTL loads. Due to the large output drive capability and the TRI-STATE feature, these devices are ideally suited for interfacing with bus lines in a bus organized system.
These devices are positive edge triggered flip-flops. Data at the $D$ inputs, meeting the set-up and hold time requirements, are transferred to the Q outputs on positive going transitions of the CLOCK (CK) input. When a high logic level is applied to the OUTPUT CONTROL (OC) input, all outputs go to a high impedance state, regardless of what signals are present at the other inputs and the state of the storage elements.

MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These parts are also plug in replacements for LS$T \mathrm{~L}$ devices and can be used to reduce power consumption in existing designs.
All inputs to this device are protected from damage due to electrostatic discharge by diodes to VCC and Ground.

## Features

- TTL input characteristic compatible
- Typical propagation delay: 15 ns
- Low input current: $1 \mu \mathrm{~A}$ maximum

■ Low quiescent current: $80 \mu \mathrm{~A}$ maximum

- Compatible with bus-oriented systems
- Output drive capability: 15 LS-TTL loads

## MM54HCT590/MM74HCT590 8-Bit Binary Counter with TRI-STATE ${ }^{\circledR}$ Output Register

## General Description

These counters are implemented using an advanced 3.0 micron silicon gate N -well microCMOS process to achieve high performance. These devices retain the low power of CMOS logic, while offering the high speed operation and large output drive typically associated with bipolar circuits. This device is input compatible with 54LS/74LS and other TTL output compatible circuits, and may be used as a lower power direct replacement for the LS equivalent device.

The MM54HCT590/MM74HCT590 contain an 8-bit binary counter which feeds an 8-bit register. The counter is incremented on the rising edge of the CCK input, provided that clock enable, $\overline{\mathrm{CCKEN}}$, is low. When the counter increments to the all ones condition ripple carry out, $\overline{\mathrm{RCO}}$, will go low. This enables either synchronous cascading of the counters by connecting the $\overline{\mathrm{RCO}}$ of the first stage to the $\overline{\mathrm{CCKEN}}$ of the second, or clocking both circuits in parallel. Ripple cascading is accomplished by connecting the $\overline{\mathrm{RCO}}$ of the first to the CCK of the second stage. A clear input is also provided which will reset the counter to the all zeros state.

The output register is loaded with the contents of the counter on the rising edge of the register clock, RCK. The outputs of this register feed TRI-STATE outputs which are enabled when the enable input, $\overline{\mathrm{G}}$, is taken low. This enables connection of this part to a system bus.
The MM54HCT590/MM74HCT590 are functional, speed and pin equivalent to the equivalent LS.TTL circuit, and may be used as a direct replacement for the equivalent LS.TTL IC. Its inputs are protected from damage due to electrostatic discharge by diodes from $\mathrm{V}_{\mathrm{CC}}$ to ground.

## Features

- Wide power supply range: 4.5 V to 5.5 V
(x) Guaranteed TTL compatible input logic levels: 2.0 V and 0.8 V
$\pm$ Wide operating frequency range: 30 MHz
- High output current drive: 6.0 mA min
. Low quiescent power consumption: $80 \mu \mathrm{~A}(74 \mathrm{HCT})$

## Connection Diagram

Dual-In-Line Package

# MM54HCT592/MM74HCT592 8-Bit Binary Counter with Input Register <br> MM54HCT593/MM74HCT593 8-Bit Binary Counter with Bidirectional Input Register/Counter Outputs 

## General Description

These counters are implemented using an advanced 3.0 micron silicon gate N -well microCMOS process to achieve high performance. These devices retain the low power of CMOS logic, while offering the high speed operation and large output drive typically associated with bipolar circuits. This device is input compatible with 54LS/74LS and other TTL output compatible circuits, and may be used as a lower power direct replacement for the LS equivalent device.

The MM54HCT592/MM74HCT592 and the MM54HCT593/ MM74HCT593 contain an 8-bit register which feeds an 8-bit binary counter. The counter is incremented on the rising edge of the CCK input, provided that clock enable, $\bar{C} C K E N$, is low. When the counter increments to the all ones condition, ripple carry out, $\overline{\mathrm{RCO}}$, will go low. This enables either synchronous cascading of the counters by connecting the $\overline{R C O}$ of the first stage to the $\overline{C C K E N}$ of the second, or clocking both circuits in parallel. Ripple cascading is accomplished by connecting the $\overline{\mathrm{RCO}}$ of the first to the CCK of the second stage. A clear input is also provided which will reset the counter to the all zeros state.
The input register is loaded on the rising edge of the register clock, RCK. The outputs of this register feed the counter. The counter is loaded with the register's contents when the clock load, $\overline{C L O A D}$, input is taken low.

The 'HCT592 differs from the 'HCT593 in that the latter device has bidirectional input/output pins. The TRI-STATE ${ }^{\circledR}$ outputs of the counter can be enabled and are active when enable input, $\bar{G}$, is taken low and input $G$ is taken high. The outputs of the counter then appear on the register inputs. This enables connection of this part to a system bus. The 'HCT593 also has a second clock enable pin, CKEN, which is active high and it also has an active low register clock enable, $\overline{\mathrm{RCKEN}}$.

The MM54HCT592/MM74HCT592 and the MM54HCT593/ MM74HCT593 are functional, speed and pin equivalent to the'equivalent LS-TTL circuit and may be used as a direct replacement for the equivalent LS-TTL IC. Their inputs are protected from damage due to electrostatic discharge by diodes from $V_{C C}$ to ground.

## Features

- Wide power supply range: 4.5 V to 5.5 V
(1) Guaranteed TTL compatible input logic levels: 2.0 V and 0.8 V
- Wide operating frequency range: 30 MHz
- High output current drive: 6.0 mA min
( Low quiescent power consumption: $80 \mu \mathrm{~A}(74 \mathrm{HCT})$

## MM54HCT640/MM144HCT640 Inverting Octal TRI-STATE® Transceiver MM54HCT643/FMAT74HCT643 True-Inverting Octal TRI-STATE Transceiver

## General Description

These TRI-STATE bi-directional buffers utilize microCMOS Technology, 3.0 micron silicon gate $N$-well CMOS, and are intended for two-way asynchronous communication between data buses. They have high drive current outputs which enable high speed operation even when driving large bus capacitances. These circuits possess the low power consumption of CMOS circuitry, yet have speeds comparable to low power Schottky TTL circuits.
All devices are TTL input compatible and can drive up to 15 LS-TTL loads, and all inputs are protected from damage due to static discharge by diodes to $\mathrm{V}_{\mathrm{CC}}$ and ground.

Both the MM54HCT640/74HCT640 and the MM54HCT643/ 74 HCT 643 have one active low enable input ( $G$ ), and a direction control (DIR). When the DIR input is high, data flows from the A inputs to the B outputs. When DIR is low, data flows from B to A. The MM54HCT640/74HCT640 transfers
inverted data from one bus to the other. The MM54HCT643/ 74 HCT 643 transfers inverted data from the $A$ bus to the $B$ bus and non-inverted data from the $B$ bus to the $A$ bus.
MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These parts are also plüg in replacements for LSTTL devices and can be used to reduce power consumption in existing designs.

## Features

- TTL Input Compatible
- Octal TRI-STATE outputs for $\mu \mathrm{P}$ bus applications: 6 mA, typical.
- High Speed: 12 ns typical propagation delay
- Low power: $80 \mu \mathrm{~A}$ maximum ( 74 HCT )

National Semiconductor

MNR54HCT688/MNR74HCT688
8-Bit Magnitude Comparator (Equality Detector)

## General Description

This equality detector utilizes microCMOS Technology, 3.0 micron silicon gate N -well CMOS to compare bit for bit two 8 -bit words and indicate whether or not they are equal. The $\overline{P=Q}$ output indicates equality when it is low. A single active low enable is provided to facilitate cascading of several packages and enable comparison of words greater than 8 bits.
This device is useful in memory block decoding applications, where memory block enable signals must be generated from computer address information.
The comparator combines the low power consumption of CMOS, but inputs are compatible with TTL logic levels, and the output can drive 10 low power Schottky equivalent loads.

MM54HCT/MM74HCT devices are intended to interface between TTL and NMOS components and standard CMOS devices. These parts are also plug in replacements for LSTTL devices and can be used to reduce power consumption in existing designs.
All inputs are protected from damage due to static discharge by diodes to $V_{C C}$ and ground.

## Features

- TTL Input Compatible
- Typical propagation delay: 20 ns

■ Low quiescent current: $80 \mu \mathrm{~A}$ maximum ( 74 HCT series)

- Large output current: 4 mA
- Same as HCT521

MM54HCU04/MM74HCU04 Hex Inverter

## General Description

These inverters utilize microCMOS Technology, 3.5 micro silicon gate P -well CMOS, to achieve operating speeds similar to LS-TTL gates with the low power consumption of standard CMOS integrated circuits.
The MM54HCU04/MM74HCU04 is an unbuffered inverter. It has high noise immunity and the ability to drive 15 LS-TTL loads. The $54 \mathrm{HC} / 74 \mathrm{HC}$ logic family is functionally as well as pin-out compatible with the standard 54LS/74LS logic family. All inputs are protected from damage due to static discharge by internal diode clamps to $\mathrm{V}_{\mathrm{CC}}$ and ground.

## Features

- Typical propagation delay: 7 ns
- Fan out of 15 LS-TTL loads

■ Quiescent power consumption: $10 . \mu \mathrm{A}$ maximum at room temperature

- Typical input current: $10^{-5} \mu \mathrm{~A}$

## Connection and Schematic Diagrams

Section 2
Semi-Custom Circuits

## Introduction

Gate arrays are very popular semi-custom IC products. They can be thought of as the next step in the evolution of complex chips.
In brief, a gate array is a geometric pattern of basic gates contained on one chip. It is possible to selectively interconnect these gates to form a complex function for cus-tomer-specific logic applications.

This concept originated a number of years ago in many computer houses. The more recent appearance of gate arrays in major new computer systems has attracted attention to this technique of providing digital circuits.

## PRODUCING THE SYSTEM•ON•A•CHIP

Gate arrays take the industry one step closer to the complete system on a single silicon chip. The objective is to combine the logic of a large number of SSI and MSI packages (which would occupy a large part of a PC board) and squeeze all this logic onto a single gate array chip. Systems designers will therefore exchange logic chip catalogs for macrocell libraries, and PC board layouts for placement and routing of interconnects on a silicon wafer. Circuit design is finally returning to the systems houses.
Through the modern miracle of software, systems designers will convert their logic diagrams into the detailed information that is needed to make IC interconnection masks. The semiconductor manufacturer will then make these masks and pattern some existing, nearly finished wafers with this custom interconnect pattern.
Software-generated test tapes will verify product functionality, and these ICs will then be shipped to the customer-a cycle that is not much different from photographic film processing: a roll of film is sent in, and prints are returned.
There are many benefits that result from the use of gate arrays. One of the more important is the reduction in the time required to design a new system. Performance
advantages also result because of higher levels of integration, yielding higher speed for the same power dissipation, or a reduction in power consumption. The smaller total number of external connections between components also increases system reliability.

## DESIGNING GATE ARRAY PRODUCTS

The major events involved in designing a gate array are shown in Figure 2-1.

Taken in sequence, the steps are:

1. The entry (by the customer) of the logic design into a computer system via a graphic capture or a netlist (an alphanumeric format).
2. A logic simulation then ensures the proper functioning. During this phase, test programs are generated and fault-graded to ensure adequate detection of bad chips. The solution to this testing problem is a major part of the gate array design and often requires additional logic. To help solve this problem, special circuitry has been included in the base array design of National's larger array chips.
3. With a proper logic diagram (which also solves the testing requirements), the next step is the placement or location of the specific macrocells. This is followed by a routing program that interconnects the macros. Transient analysis programs can then show the timing to expect since the added capacitance loading of the actual interconnect lines is used.
4. From here, pattern generator (PG) tapes are made which allow the fabrication of the masks: 1st-layer metal, 2nd-layer metal, and the via mask for connection between the metal layers. These masks are then used to pattern your custom logic onto existing silicon wafers.
5. Finished parts are final tested and shipped, completing the design cycle.

FIGURE 2-1. The Development System for Gate Arrays

## PROVIDING NEW GATE ARRAY TECHNOLOGIES

National continues to develop new technologies for highperformance gate arrays and offers a dual-metal silicongate CMOS family, as well as a high-speed bipolar ECL family. The SCX series CMOS gate arrays have been in production in both 3 -micron and 2-micron drawn geometries and provide typical gate delays of 2 ns and 1 ns , respectively. For applications demanding sub-nanosecond delays, the MCA series of ECL gate arrays is available and provides the ultimate in high-speed performance.

## DESIGN AUTOMATION IS THE KEY TO SUCCESS

National's design automation tools start with a full complement of hardware macros, the basic building blocks from which a user can select functions to implement his logic. From these logic blocks come an ever increasing list of software macros. These are made up of hardware macros that have been pre-arranged and verified for 7400 series logic implementation.
All hardware and software macros are supported by a fully integrated CAE/CAD system that includes graphic workstation data entry, timing verification, logic simulation, fault grading, design verification, and $100 \%$ auto-place-and-route.

The present product offerings in CMOS gate arrays are listed in Figure 2-2.

Notice that the new $2 \mu \mathrm{~m}$ products have internal propagation delays of only 1 ns and can be operated at up to 110 MHz toggle frequencies. The largest array size contains 6090 equivalent 2 .input gates.

## THE USE OF NEWER PACKAGES

These new gate array products have large numbers of potential inputs and outputs to accommodate different design architectures. National has developed new packages for these devices such as the 124-pin grid array (PGA) shown in Figure 2-3.

Specific array designs, however, can be done in a wide variety of package options, including leaded chip carriers, plastic and ceramic leadless chip carriers, and standard DIPs. Lead counts range from 28 to 172 pins.
The customer offerings in semi-custom will be expanded to include cell arrays and functional block arrays. This is a very dynamic market-please contact your National sales representative for the current status of our semi-custom circuit capability.

## Features

■ Latch-up proof, state-of-the-art $3 \mu / 2 \mu$ dual-metal silicon-gate microCMOS technology

- Ultra-high performance-2 ns/1 ns typical gate delays
- High density-to the equivalent of 60002 -input gates
- Self-test capability-available on 6000-gate devices
- Advanced high-density packages-up to 172 pins
- Complete hardware/software macrocell libraries
- $100 \%$ auto-place-and-route-supported by a fully integrated design automation system
- Full 883B screening over military temperature range

# SCX 6324 microCMOS 2．4k Gate Array NSOOOU Option User＇s Note 

## Introduction

The SCX 6324 CMOS 2．4k Gate Array is fabricated on a 3 －micron，dual metal， N －Well， 5 V microCMOS Process which typically provides internal propagation delay of 2 ns for a 2 －input NAND gate．
The Test Chip Option of the SCX 6324A（NSO00U option） contains all macro cells currently available for design （as of October，1982）．It is intended for engineering eval－ uation and as a sampling part for AC performance dem－ onstration．

A schematic drawing follows and a test setup scheme is shown on page 2－9．

## Test Set Up

The Test Chip option of the SCX6324 contains circuitry for engineering evaluation of macro functions that are currently available．Some circuits may have unprotected inputs／outputs，thus evaluations should be done under a controlled environment．Users are advised to use only those circuits that are mentioned in this note．Connec－ tions to any other pins may cause damage to the device．

A test set－up scheme is suggested in Figure 4 for refer－ ence，together with a selection table for each macro given in Table 1.
Input Pull－Up：All inputs（except pins 87 and 88）are provided with internal pull－up；grounded inputs will source approximately $8 \mu \mathrm{~A}$ each at $25^{\circ} \mathrm{C}$ and $\mathrm{V}_{D D}=5 \mathrm{~V}$ ．
AC Performance of a Macro：The outputs of all macros are fed to the external pins via a MUX and an output buf－ fer，so their exact AC performance should be found by subtracting the delay due to these MUXs and buffers． Pins 59 and 55 （labelled as＂input signal reference＂）can be used to determine this extra delay．
Internal TRI－STATE ${ }^{\oplus}$ Macro：S9 and S10 are TRI－STATE buffers intended for use within the array．They are brought out to the external pin in this Test Chip option．A scope probe with low loading should be used to give better approximation of their performance．A low capaci－ tance FET probe is recommended．It is unlikely that much less than $8-10 \mathrm{pF}$ of parasitic loading can be achieved．（See Note 2．）
Unprotected I／O Pins：There are I／O pins in this option that are not protected．Extreme care should be exercised in using them to avoid latch－up，oxide rupture，etc．
NOTE：This document also applies to the 2－micron SCX 6224 test chip in terms of circuit configuration and pin arrangement．

Metal Loading Evaluation：Three strings of inverters are included in this Test Chip for the metal loading evalua－ tion．One is without any extra metal loading except for interconnect；the other two are loaded with $200-\mathrm{mil}$ run of either metal 1 or metal 2 at each inverter stage．Refer to the schematic drawing for details．（See Note 1．）

## Notes：

1．Other than on these gate strings（see＂Metal Loading Evaluation＂ above），no additional loading capacitance is added．All other macros are generally connected with a minimal amount of interconnect－the amount of parasitic capacitance incurred is not shown．
2．All macros intended for internal array use，but brought directly to output pins，are not protected against latch－up．（All true output buffer options of the I／O are fully protected．）

## On－Chip Test Circuit

All options of the SCX6324 are provided with on－chip test circuitry，at the cost of a single input pin，to create TEST MODE．With this pin active（LOW），two additional pre－defined inputs are jointly employed to force all out－ puts to HIGH，LOW or Hi－Z states and thus reduce test time in gathering output parametrics．These two pins further function as conventional inputs（either TTL or CMOS when in TEST MODE，HIGH）with no performance penalty apparent to the user．
TEST MODE CONTROL（TMC）：A LOW at this input will activate the test circuitry．All output buffers are to be driven by TEST DATA（DT）and TRI－STATE TEST CONTROL（TSTC）pins．
TRI－STATE TEST CONTROL（TSTC）：A HIGH at this input， together with TMC low，puts all TRI－STATE output buf－ fers to Hi －Z state．
TEST DATA（DT）：Input to this pin，with TMC low，forces all outputs to either HIGH or LOW．

### 1.0 GENERAL DESCRIPTION

National Semiconductor's CMOS gate array families utilize a dual layer metal technology (microCMOS) to achieve operating speeds similar to Schottky-TTL with the inherent lower power consumption of standard CMOS integrated circuits. The families are available in 3 -micron (as drawn) and 2 -micron process technology. The range of complexity is currently from 600 to 6000 gates. The gates are arranged in cells. Each cell has the equivalent of three 2 -input NAND or NOR gates. All outputs have the ability to drive 10 LSTTL loads. All inputs have high noise immunity and are protected from static discharge.
National Semiconductor supports gate array designs with a variety of user/vendor interfaces. This ranges from producing arrays from the user's schematic to accepting databases for mask generation. A large dedicated staff of gate array professionals is available to help the user determine the most efficient and cost effective way to interface on any given design.
The design automation tools include workstation or text file entry (for schematic capture), logic and timing verifiers to substantiate the actual design, fault grading analysis to gauge testability and a large selection of macros (hardware and software) to speed and simplify the design.

### 2.0 PRODUCT FEATURES

- 2.0 ns internal propagation delay ( 3 -micron)
- 1.0 ns internal propagation delay (2-micron)
- CMOS power dissipation
- All inputs and I/Os protected from over-voltage and latch-up
- LSTTL drive capability
- TTL/CMOS inputs and I/Os (programmable)
- Internal test circuitry
- Full design automation support
-Schematic capture
-Logic simulator with timing information
-Fault grading
->80\% cell utilization
- 100\% automatic placement and routing
- Extensive hardware and software macro library
- Multiple power rail pin connections
- Multiple packaging options in ceramic, plastic, leaded and leadless
- Pin counts to 124
- Full military specifications
- Alternately sourced

## 2.1 microCMOS Process and CIrcuit Personalization

The microCMOS process developed by National is based on P-type starting material, N -well technology and oxide isolation. After the basic transistors are formed (in their respective cells), two separate layers of metalization (M1 and M 2 ) are placed on the wafers.
The processing steps and tooling requirements for all the wafers up to the metal layers are common and fixed. Circuit patterns-called "options"-are defined by the two metal layers and the VIAs. In this way, the user's design (or circuit personality) is imposed on the wafer.

All SCX gate arrays in the family use the same basic internal cell. There are eight pairs of $N$ and P-type MOS transistors in each cell (see Figure 2). The power and ground lines ( $V_{D D}$ and $V_{S S}$ buses, respectively) run up and down the cell. This cell is repeated in all four directions to form columns and rows in the core of the array. The structure of the internal core is optimized to the size of each family member.
National Semiconductor maintains an inventory of gate array wafers fabricated up to but before metalization. As the customer's options are designed and the last three patterns finalized, wafers are taken out of inventory and the fabrication process completed for the metal layers.
In this way, National Semiconductor can provide gate array users with quick turn-around cost effective designs while maintaining the quality, reliability and production control of an in-house (5-inch) wafer fab line.

### 2.2 Gate Array Basic Cell

Figure 1 and Figure 2 show a microCMOS cross section and the basic internal cell respectively. The geometries are not drawn to scale and the exact topology has been modified for illustration purposes.

FIGURE 1. Cross Section

FIGURE 2. Cell

### 2.3 Power Dissipation

An outstanding feature of microCMOS circuits is their low power dissipation. CMOS circuits draw electrical current for basically two reasons:
(1) During transition from a logic " 0 " to a logic " 1 " or vice versa, there exists a finite time when the P-channel and N -channel devices associated with the logic element are both conducting. The CMOS circuit consumes power during this transition.
(2) When signals change state, the distributed capacitance in the circuit (and its load) need to be either charged or discharged. The electrical current required for this purpose increases power consumption.
Thus, power dissipation is dependent on operating voltage, nodal capacitance and the frequency of circuit operation. Mathematically speaking:

$$
P_{O}=C V^{2} F
$$

For estimation purposes, the value of:
$35 \mu \mathrm{~W} /$ gate/ MHz per gate equivalent can be used for elements within the array.
$700 \mu \mathrm{~W} / \mathrm{MHz} /$ output buffer at 15 pF load or $1500 \mu \mathrm{~W} / \mathrm{MHz} /$ output at 50 pF load, can be used for the output buffers.

Power dissipation in a CMOS array is typically dominated by output buffers driving large capacitive loads.

Figure 3 will help in estimating power consumption in a particular design.

FIGURE 3. Power Consumption vs Frequency

### 2.4 Absolute Maximum Ratings

Exceeding the following absolute maximum ratings may

| Supply Voltage | -0.5 V to 7 V |
| :--- | ---: | ---: |
| Input or Output Voltage | -0.5 V to $\mathrm{V}_{\mathrm{DD}}+0.5 \mathrm{~V}$ |
| Storage Temperature | $-65^{\circ} \mathrm{C}$ to $150^{\circ} \mathrm{C}$ |
| Power Dissipation (Package Dependent) | 1 W |
| Lead Temperature (Soldering, 10 seconds) | $300^{\circ} \mathrm{C}$ |

result in permanent damage to the device.

|  | Min | Max | Units |
| :---: | :---: | :---: | :---: |
| $V_{D D}$, Supply Voltage | 2 | 6 | V |
| $\mathrm{V}_{1}, \mathrm{~V}_{\mathrm{O}}$, Input or Output Voltage | $V_{S S}$ | $V_{D D}$ | V |
| Io, High or Low Level Output Current | 0 | $\pm 25$ | mA |
| $\mathrm{I}_{\mathrm{DD}}, \mathrm{V}_{\text {DD }}$ or $\mathrm{V}_{S S}$ Current per Pad | 0 | $\pm 25$ | mA |
| $T_{A}$, Ambient Operating Temperature | -40 | +85 | ${ }^{\circ} \mathrm{C}$ |

2.6 DC Electrical Characteristics
$V_{D D}=5 \mathrm{~V} \pm 10 \%, \min /$ max limits apply over recommended operating temperature range unless otherwise specified.

| Symbol | Parameter | Min | Max | Units |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\mathrm{IH}}$ | High Level Input Voltage at $\mathrm{V}_{\mathrm{O}}=0.1 \mathrm{~V}$ or $\mathrm{V}_{\mathrm{DD}}-0.1 \mathrm{~V}, \mathrm{I}_{0}=20 \mu \mathrm{~A}$ | 0.7 VDD |  | V |
| $\mathrm{V}_{\text {IL }}$ | Low Level Input Voltage at $\mathrm{V}_{\mathrm{O}}=0.5 \mathrm{~V}$ or $\mathrm{V}_{\text {DD }}-0.1 \mathrm{~V}, \mathrm{I}_{\mathrm{O}}=20 \mu \mathrm{~A}$ | . | $0.2 \mathrm{~V}_{\text {DD }}$ | V |

### 3.0 TOPOLOGY AND ROUTING RESOURCE DISTRIBUTION

The specific topology and routing resource distribution have been tailored for each family member. Architectural considerations include the ratio of inputs and I/Os to total cell count, power consumption and package inductance to power pins (for simultaneous switching outputs) and

TL/U/5725-3
2.5k

TLU/U5725.5
routing resources consistent with automatic place and route software. Irternal cell utilizations of greater than $80 \%$ can be expected.
Individual topologies and a family summary follow.

### 4.0 ON-CHIP TEST CIRCUITRY

Each of the SCX gate arrays is provided with dedicated onchip test circuitry. This circuitry forces all the outputs to specific states to facilitate output parametric testing. These parametric tests include leakage and current sourcing/sinking measurements on all output pins.
The on-chip test circuitry is enabled by a dedicated test mode control (TMC) pin. This pin is set aside for testing and cannot be used for any other purpose. A low at this input will activate the on-chip test circuitry. When the onchip test circuitry is activated, the states of all outputs are determined by two other inputs; these are TRI-STATE test control (TSTC) and data test (DT). The TSTC and DT can share input pins with the user's design. They are only active when the TMC is enabled. The TSTC input has precedence over the DT input.

The TMC input is active for the following discussion.
When the TSTC input is active, all the output buffers are put into a high impedance mode. When TSTC is not active, the states of the output buffers are determined by the DT input. These two inputs can be assigned to any of the input pins. However, depending on the type of the input macro used for these two inputs, the outputs can have quite different states. This is because macros may have inverting or non-inverting inputs.

## ON-CHIP TEST CIRCUITRY TRUTH TABLE

| TMC | DT | TSTC | Output |
| :---: | :---: | :---: | :---: |
| 0 | $X$ | Active | TRI-STATE |
| 0 | Non-Active | Non-Active | 1 |
| 0 | Active | Non-Active | 0 |

DEFINITION OF TEST INPUT STATES

|  | Non-Inverting <br> Macros | Inverting <br> Macros |
| :---: | :---: | :---: |
| Non-Active | 0 | 1 |
| Active | 1 | 0 |

| Array <br> Name | Internal <br> Cells | Input <br> Cells <br> (Note 2) | IIO <br> Cells | Total <br> Pins <br> (Note 1) | $\mathbf{V}_{\text {DD }}$ <br> Pins | V $_{\text {SS }}$ <br> Pins |

Nòte 1: One of the pins is permanently set aside for testing purposes. Note 2: Input and I/O cells are not considered part of the internal cell count.

### 5.0 MACROS

Three types of macros are available for designers to use: hardware macros, software macros (National Semiconductor standard library), and user generated software macros.

### 5.1 Hardware Macros

The SCX family of gate arrays offers an extensive library of hardware macros. Each macro has been fully characterized and functionally proven. The designer can select those macros that most efficiently implement the design. The electrical performance of the macros is characterized at two sets of conditions: best and worst-case. Under each set of conditions, the output loading is specified at 0 pF and 1.0 pF . The 1.0 pF load is equivalent to a fan-out of 3 and includes 100 mils length of metal interconnect. A single input load is equivalent to 0.17 pF and is defined as a load factor of 1 .

National Semiconductor has very tight wafer fabrication guidelines. However, process parameters still do vary from wafer-to-wafer, lot-to-lot. The electrical specifications of the macros take into account such variations.

The logic macros are categorized by the number of array cells that each occupies. The prefix of the macro identifies the category.

| Prefix | No. of Cells Occupied |
| :---: | :---: |
| S | 1 |
| D | 2 |
| T | 3 |
| Q | 4 |
| F | 5 |
| H | 6 |

Note: The ' $\mathbf{C 0 0 0}$ ' designator is a common reference used between National Semiconductor and its alternate source for the purpose of consistency with users.

### 5.2 Software Macros

In addition to the pre-designed hardware macros, National Semiconductor offers a library of software macros. These software macros emulate the functions of the popular 7400 and 4000 logic families. From the designer's vantage point, these software macros are utilized as though they were hardware macros. The actual implementation of these higher order functions is handled by the design automation tools in a process that virtually expands the software macro into its hardware macro primitives.
Since the software macros reside in the design automation system, a designer may copy a software macro into
-
his design, modify it to meet some special consideration, rename it, then reference it as a special or new software macro. This procedure is coordinated with NS gate array group.

National Semiconductor adds popular software macros to the existing library as required to meet user needs.

A representative list is shown in Table I. The cell count is a 'will not exceed' number, unused portions of cells are available for use in unrelated portions of the design.

### 5.3 Software Macros (User Generated)

The user always has the option of generating higher order software macros. This is true regardless of where the user decides to interface with the design automation system.

At the workstation level, the user simply creates the desired function from existing hardware macros, stores the function under a unique identifier name, then recalls it as a block of logic as required.

In the text file mode of schematic capture the user defines the higher order function in terms of the basic hardware macros. These higher order (custom) functions are then 'called' in the same manner as any other software macro.

| PA Device | Cell Count |

### 6.0 PERIPHERAL MACROS

Interfacing to the SCX gate arrays is done through the peripheral buffers. There are two types of peripheral cells; input only and bi-directional I/O cells. The peripheral macros are not included in the count of internally available cells.

The buffers are located around the periphery of the die and the exact configuration is dependent on the particular family member under consideration. Reference section 3 for specific locations of input and I/O cells.

### 7.0 PACKAGING

The SCX family of microCMOS gate arrays is offered in a very wide variety of packages. The user is provided with many choices in terms of both package type and lead count. The package types offered include ceramic pin grid arrays, leaded ceramic chip carriers (LDCC), leadless ceramic chip carriers (LCC), plastic leaded chip carriers (PCC), ceramic DIPs, and plastic DIPs.
The availability of such a large variety of packages gives the user flexibility in making the following choices:
-Ceramic versus plastic
-Through-hole mount versus surface mount
-Variety of lead counts
The specific packages offered are listed in Table Ila.
Surface mounting of multi-lead components is rapidly gaining popularity. To provide the user flexibility, National Semiconductor offers its CMOS gate arrays in several surface mount package options: leaded and leadless ceramic chip carrier and the plastic chip carrier.
Surface mounting refers to component attachment, whereby the component leads or pads rest on the surface of the PCB instead of the traditional approach of inserting the leads into through-holes which go through the board. With surface mounting there are solder pads on the PCB which align with the leads or pads on the component. The resulting solder joint forms both the mechanical and electrical connections.

The primary reason for surface mounting is to allow leads to be placed closer together than the 0.100 inch standard for DIPs with through-hole mounting. Through-hole mounting on smaller than 0.100 inch space is difficult to achieve in production and is generally avoided. The move to 0.050 inch lead spacing offered with the current generation of surface mounted components, along with a switch from a dual-in-line format to a quad format, has achieved a threefold increase in component mounting density. A need to achieve greater density is a major driving force in today's marketplace.

Learning how to surface mount components to printed circuit boards requires the user to implement an assembly process not typically associated with through-hole insertion/wave soldering assembly methods.
Surface mounting involves three basic process steps:

1) Application of solder or solder paste to the printed circuit board
2) Positioning of the component onto the printed circuit
3) Reflowing of the solder or solder paste.

Table llb lists the manufacturers currently offering sockets for each of the advanced package options listed in this data sheet. A matrix of which manufacturers to contact for each socket option is provided. The listing is divided into test/burn-in and production categories. There may be some individual sockets that will cover both requirements.

### 8.0 PROPAGATION DELAYS

Propagation delays in CMOS arrays are a function of several factors:

- Supply voltage
- Junction temperature
- Process tolerance
- Fan-out loading
- Interconnection routing
- Input signal direction

To assist the designer in evaluating circuit performance under all operating conditions, National Semiconductor guarantees DC and AC parametrics over the full voltage and temperature range, as well as best-case and worstcase propagation delays. Process tolerance is included in the specifications.

Delays other than three for fan-out loading may be extrapolated for loads other than shown.

For example: a 2-input NAND (S1) drives six loads. What is the worst-case LO to HI delay?

From Table III
$t_{\text {PLH }}$ for $0 \mathrm{pF}=1.82 \mathrm{~ns}$ (0 loads)
$\mathrm{t}_{\mathrm{PLH}}$ for $1 \mathrm{pF}=4.95 \mathrm{~ns}$ ( 3 loads)
The delay per load $=(4.95-1.82) / 3=1.05 \mathrm{~ns}$
Total delay $=$ base delay ( 0 load ) + six loads
$8.12 \mathrm{~ns}=1.82 \mathrm{~ns}+6$ ( 1.05 ns )
What is the delay if the power supply is maintained at 5 V and junction temperature is $80^{\circ} \mathrm{C}$ (approximately $65^{\circ}$ ambient)?

From scaling factors (Table III note):
Worst-case junction temperature $=100^{\circ} \mathrm{C}$
New junction temperature $=80^{\circ} \mathrm{C}$
Improvement factor $=\frac{0.3 \%}{{ }^{\circ} \mathrm{C}}\left(100^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}\right)=6 \%$
Worst-case voltage $=4.5 \mathrm{~V}$
New voltage $=5.0 \mathrm{~V}$
Improvement factor $=\frac{2 \%}{0.1 \mathrm{~V}}(5.0 \mathrm{~V}-4.5 \mathrm{~V})=10 \%$
Derating factor $=(1-0.06)(1-0.1)=0.846$
Total delay $($ scaled $)=8.12(0.846)=6.86 \mathrm{~ns}$
This form of calculation is handy for making estimates of critical paths during the initial design phase and can be used as a guide to determine which technology to use (i.e., $3 \mu$ or $2 \mu$ ). The actual AC performance prediction will be provided by the design automation system after the designer has functionally verified his design in the logic simulator.

Propagation delays as a function of temperature and supply voltage are shown in Figures 4 and 5 respectively. Utinization of these curves will speed the estimation of performance at other then specified values.

Representative macro types for the $3 \mu$ (Table III) and $2 \mu$ process (Table IV. are presented for comparison. Reference SCX family macro library book for complete specifications.

FIGURE 5. CMOS Propagation Delays as a Function of Supply Voltage

### 9.0 DESIGN AUTOMATION SYSTEM

The design automation system offers the end user a variety of interface points and techniques.
Figure 6 shows the standard gate array development flow and responsibilities. Alternative flows are available and are presented in Section 11.
The standard flow consists of four major quadrants. They are the user's site, user's responsibilities, National Semiconductor's technology center, National Semiconductor's responsibility. These represent the 'where' and 'who' aspects of task responsibility and location.

## User Site

Logic design and definition are the user's responsibility and are completed at his/her site.

The design file consists of the netlist (wiring diagram) and the test vectors (pattern file). Each can be generated in a text file or as the output from a 'workstation'. The syntax of these files is in the 'hardware design language'.

The evaluation and acceptance of the completed prototypes are done by the user at his/her facilities. National Semiconductor offers technical assistance if necessary.

FIGURE 6. Standard Gate Array Development Process and Responsibilities

## National Semiconductor Technology Center

Training includes actual interaction with the design automation system and, depending on the level of user experience, requires from three to five days to complete. All of the considerations necessary for the successful completion of the design are covered during the training. Topics such as, hardware (i.e., speed, power, pinouts) and software considerations (i.e., logic simulation, fault grading, critical path analysis) are tailored to meet the user's needs. Training is provided at the closest technology center. Contact the local sales representative for the location nearest you.

Functional verification of the logic is accomplished by submitting the netlist and pattern files to the logic simulator. The simulator will predict the output results of the specified logic for the applied vectors. The designer can then determine if the specified logic meets the design
objectives. Simulation under actual 'loaded' conditions occurs after functional verification and fault grading. Functional verification is the responsibility of the user.

Fault grading is a measure of the ability of the supplied vectors to detect induced logic errors (i.e., on-chip shorts). The vectors supplied eventually become the functional portion of the final production test tape. It is important that the fault grading figure of merit reach $85 \%$. Fault grading is the responsibility of the user.

Performance estimation is the prediction that the logic simulator makes by considering actual macro loading and a projection of the interconnect lengths. This projection is based on an algorithm which relates fan-out to probable trace length. Performance estimation is the responsibility of the user.

Place and route are the actual implementation of the user's design file. Two pieces of design automation software are used to complete the routing.

Automatic place and route software completes the majority of interconnects and in most cases completes the entire array.
Interactive graphics software is used to complete any unrouted interconnects.
Place and route are the responsibility of National Semiconductor.

Performance verification is the rerunning of the 'performance estimation' software with the actual cell placements and associated trace lengths. Performance verification is the responsibility of the user.
Mask generation, assembly and test are completed by National Semiconductor.
Prototype evaluation and acceptance are the responsibility of the user.
National Semiconductor has a large staff of applications and consulting engineers available to assist users at any point in the array development process.

### 10.0 DESIGN EXAMPLE

The two most popular ways of interfacing to the design automation system are 1) alphanumeric text entry and 2) workstation output. A different example will be given for each. In either case the design automation system requires two basics files to operate.
Network (File): The network file is the 'wiring diagram' of the design. It represents how the array is to be 'wired'. More specifically, it is the manner in which the hardware macros are interconnected. The syntax of the network file is specified by a hardware design language (HDL).
Pattern (File): The pattern file represents the stimuli or sequence of signals used to exercise the design specified by the network file. The pattern file ultimately becomes the functional portion of the final test tape used to screen production devices.
The logic simulator operates on the network and pattern files and predicts the logic output as a function of the pattern file.

TL/U/5725.11
The simulator has two modes of operation. The first mode is used to verify the logical integrity of the design. The second mode considers capacitive circuit loading and anticipated wire lengths. The result of the second mode is the
performance that can be expected after the circuit has been placed and routed.

The basic form of a network file is as follows.

The macro call syntax for the following circuit fragment is as specified.

TL/U/5725-12

If the designer were using the alphanumeric text mode of data entry, each unique macro and macro type would be specified in the above manner until the entire network had been specified.

In the workstation mode of schematic capture the designer would call and name each desired macro, then graphically interconnect each macro in the required fashion. The workstation would then 'compile' the schematic into the network file.

The design of a four-bit latch with TRI-STATE output is presented.

### 11.0 ALTERNATIVE INTERFACES

Flexibility in the design automation system allows a variety of user/vendor interfaces. Options include:

- User supplies schematic, timing diagrams and parametric specifications. National Semiconductor implements the array.
- User 'captures' the design at his facility or at a National Semiconductor technology center. National Semiconductor supports a wide range of communication protocols for interfacing to industrial (mainframe) or personal computers. These are available with or without error control and communication rates of 300 to 9600 baud.
- User follows basic array development flow specified in Figure 6.
- User generates logic simulator compatible files from his workstation. Completes the array using National Semiconductor's design automation system.
- User generates compatible design files and logic verification in his/her simulator, then interfaces to design automation system at either fault grading, performance estimation, or 'place and route'.
- User supplies completed design files from National Semiconductor's alternate source, effectively entering design automation system just prior to digitizing.
- User provides all design files necessary for mask generation, essentially a 'customer owned tooling' (COT) approach.

## Introduction

The new microCMOS technologies are also being used to provide functional-specific standard products. These LSI/ VLSI circuits are of relatively large complexity and represent additional uses for the advanced CMOS processes.
A special group of LSI/VLSI circuitry exists within the popular MM54/74HC microCMOS logic family. These products make use of the product designation MM54/74HC9XX. An example of this 900 series is the MM74HC942-a high performance, low power, Bell 103 compatible single-chip modem. This product combines both digital and linear circuitry to bring the benefits of system level integration to modem and systems designers.

When considering a new design, it is important to keep in mind the wide range of standard products that are available. In addition to memories and microprocessors, the products in this section also enjoy high volume usage and can provide cost savings as well as reduce the complexity and amount of semi-custom or custom circuitry required to implement a new system.

National Semiconductor

## MM5368 CMOS Óscillator Divider Circuit

## General Description

The MM5368 is a CMOS integrated circuit generating 50 or $60 \mathrm{~Hz}, 10 \mathrm{~Hz}$, and 1 Hz outputs from a 32 kHz crystal ( $32,768 \mathrm{~Hz}$ ). For the 60 Hz selected output the input time base is divided by 546.133 , for the 50 Hz mode it is divided by 655.36 . The $50 / 60 \mathrm{~Hz}$ output is then divided by 5 or 6 to obtain a 10 Hz output which is further divided to obtain a 1 Hz output. The $50 / 60 \mathrm{~Hz}$ select input can be floated for a counter reset.

## Features

- $50 / 60 \mathrm{~Hz}$ output
- 1 Hz output
- 10 Hz output
- Low power dissipation
- Fully static operation
- Counter reset
- $3 \mathrm{~V}-15 \mathrm{~V}$ supply range
- On-chip oscillator - tuning and load capacitors are the only required external components besides the crystal. (For operation below 5 V it may be necessary to use an $\sim 1 \mathrm{M} \Omega$ pullup on the oscillator output to insure start-up.)

| Logical " 0 " (1/L) | $V_{\text {DD }}=15 \mathrm{~V}, \mathrm{~V}_{\text {IN }} \leq 0.1 \mathrm{~V}_{\text {DD }}$ |  |  | 1 | mA |

## Functional Description

(Figure 1)

The MM5368 initially divides the input time base by 256. From the resulting frequency ( 128 Hz for 32 kHz crystal) 8 clock periods are dropped or eliminated during 60 Hz operation and 28 clock periods are eliminated during 50 Hz operation. This frequency is then divided by 2 to obtain a 50 or 60 Hz output. This output is not periodic from cycle to cycle; however, the waveform repeats itself every second. Straight divide by 5 or 6 and 10 are used to obtain the 10 Hz output and the 1 Hz outputs.

The 60 Hz mode is obtained by tying pin 7 to VDD. The 60 Hz output waveform can be seen in Figure 3. The 10 Hz and 1 Hz outputs have an approximate $50 \%$ duty
cycle. In the 50 Hz mode the $50 / 60$ select input is tied to $\mathrm{V}_{\mathrm{SS}}$. The 50 Hz output waveform can be seen in Figure 3. The 10 Hz output has an approximate $40 \%$ duty cycle and the 1 Hz output has an approximate $50 \%$ duty cycle.

For the $50 / 60 \mathrm{~Hz}$ select input floating, the counter chain is held reset, except for the initial toggle flip-flop which is needed for the reset function. A reset may also occur when the input is switched (Figure 4). To insure the floating state, current sourced from the input must be limited to $1.0 \mu \mathrm{~A}$ and current sunk by the input must be limited to $1.0 \mu \mathrm{~A}$ for $\mathrm{V}_{\mathrm{DD}}=3 \mathrm{~V}$.

## MM5369 Series 17 Stage Oscillator/Divider

## General Description

The MM5369 is a CMOS integrated circuit with 17 binary divider stages that can be used to generate a precise reference from commonly available high frequency quartz crystals. An internal pulse is generated by mask programming the combinations of stages 1 through 4, 16 and 17 to set or reset the individual stages. The MM5369 is advanced one count on the positive transition of each clock pulse. Two buffered outputs are available: the crystal frequency for tuning purposes and the 17th stage output. The MM5369 is available in an 8 -lead dual-in-line epoxy package.

## Features

- Crystal oscillator
- Two buffered outputs

Output 1 crystal frequency
Output 2 full division

- High speed ( 4 MHz at $V_{D D}=10 \mathrm{~V}$ )
- Wide supply range 3-15V
- Low power
- Fully static operation
- 8 lead dual-in-line package
- Low current

## Options

| Logical "0" |  |  |  | 1.0 | V |

Note: For 3.58 MHz operation, $\mathrm{V}_{\mathrm{DD}}$ must be $\geq 10 \mathrm{~V}$.

## Functional Description

A connection diagram for the MM5369 is shown in Figure 1 and a block diagram is shown in Figure 2.

## TIME BASE

A precision time base is provided by the interconnection of a $3,579,545 \mathrm{~Hz}$ quartz crystal and the RC network shown in Figure 3 together with the CMOS inverter/ amplifier provided between the OSC IN and the OSC OUT terminals. Resistor R1 is necessary to bias the inverter for class A amplifier operation. Capacitors C1 and C2 in series provide the parallel load capacitance required for precise tuning of the quartz crystal.

The network shown provides $>100 \mathrm{ppm}$ tuning range when used with standard crystals trimmed for $\mathrm{C}_{\mathrm{L}}=$ 12 pF . Tuning to better than $\pm 2 \mathrm{ppm}$ is easily obtainable.

## DIVIDER

A pulse is generated when divider stages 1 through 4, 16 and 17 are in the correct state. By mask options, this pulse is used to set or reset individual stages of the counter. Figure 4 shows the relationship between the duty cycle and the programmed modulus.

## OUTPUTS

The Tuner Output is a buffered output at the crystal oscillator frequency. This output is provided so that the

- crystal frequency can be obtained without disturbing the crystal oscillator. The Divide Output is the input frequency divided by the mask programmed number. Both outputs are push-pull outputs.

## MM53107 Series 17-Stage Oscillator/Divider

## General Description

The MM53107 is a low threshold voltage CMOS integrated circuit with 17 binary divider stages that can be used to generate a precise reference from a 2.097152 MHz quartz crystal. An internal pulse is generated by the combinations of stages $1-4,16$ and 17 to set or reset the individual stages. The MM53107 is advanced one count on the positive transition of each clock pulse. One buffered output is available: the 17th stage 60 Hz output. The MM53107 is available in an 8 -lead dual-in-line epoxy package.

## Features

m. Input frequency-2.097152 MHz

- Output frequency-60Hz
- Crystal oscillator
- High speed ( 2 MHz at $\mathrm{V}_{\mathrm{DD}}=2.5 \mathrm{~V}$ )
- Wide supply range $2.5 \mathrm{~V}-6 \mathrm{~V}$
- Low power ( 0.5 mW @ $2 \mathrm{MHz} / 2.5 \mathrm{~V}$ )
- Fully static operation
- 8-lead dual-in-line package

## Functional Description

A connection diagram for the MM53107 is shown in Figure 2 and a block diagram is shown in Figure 1.

## TIME BASE

$A$ "precision time base is provided by the interconnection of a $2,097,152 \mathrm{~Hz}$ quartz crystal and the RC network shown in Figure 3 together with the CMOS inverter/ amplifier provided between the Osc In and the Osc Out terminals. Resistor R1 is necessary to bias the inverter for class A amplifier operation. Capacitors C1 and C2 in series provide the parallel load capacitance required for precise tuning of the quartz crystal.

The network shown provides $>100 \mathrm{ppm}$ tuning range when used with standard crystals trimmed for $C_{L}=$ 12 pF . Tuning to better than $\pm 2 \mathrm{ppm}$ is easily obtainable.

## DIVIDER

A pulse is generated when divider stages 1-4, 16 and 17 are in the correct state. This pulse is used to set or reset individual stages of the counter, the modulus of the counter is 34,952 to provide 60 Hz .

## OUTPUT

The Divide Output is the input frequency divided by 34,952 . The output is a push-pull output.

National Semiconductor
MM58167A Microprocessor Real Time Clock

General Description

The MM58167A is a low threshold metal gate CMOS circuit that functions as a real time clock in bus oriented microprocessor systems. The device includes an addressable real time counter, 56 bits of RAM, and two interrupt outputs. A POWER DOWN input allows the chip to be disabled from the rest of the system for standby low power operation. The time base is a $32,768 \mathrm{~Hz}$ crystal oscillator.

## Features

- Microprocessor compatible (8-bit data bus)
- Milliseconds through month counters
- 56 bits of RAM with comparator to compare the real time counter to the RAM data
- 2 INTERRUPT OUTPUTS with 8 possible interrupt signals
■ $\overline{\text { POWER }} \overline{\text { DOWN input that disables all inputs and out. }}$ puts except for one of the interrupts
- Status bit to indicate rollover during a read
b $32,768 \mathrm{~Hz}$ crystal oscillator
■ Four-year calendar (no leap year)
- 24 -hour clock

## Functional Description

## Real Time Counter

The real time counter is divided into 4 -bit digits with 2 digits being accessed during any read or write cycle. Each digit represents a BCD number and is defined in Table I. Any unused bits are held at a logical zero during a read and ignored during a write. An unused bit is any bit not necessary to provide a full BCD number. For example tens of hours cannot legally exceed the number 2 , thus only 2 bits are necessary to define the tens of hours. The other 2 bits in the tens of hours digit are unused. The unused bits are designated in Table las dashes.

The addressable portion of the counter is from milliseconds to months. The counter itself is a ripple counter. The ripple delay is less than $60 \mu \mathrm{~s}$ above 4.0 V and $300 \mu \mathrm{~s}$ at 2.0 V .

## RAM

56 bits of RAM are contained on-chip. These can be used for any necessary power down storage or as an alarm latch for comparison to the real time counter. The data in the RAM can be compared to the real time counter on a digit basis. The only digits that are not compared are the unit ten thousandths of seconds and tens of days of the week (these are unused in the real time counter). If the two most significant bits of any RAM digit are ones, then this RAM location will always compare.

The RAM is formatted the same as the real time counter, 4 bits per digit, 14 digits, however there are no unused bits. The unused bits in the real time counter will compare only to zeros in the RAM.

## Interrupts and Comparator

There are two interrupt outputs. The first and most flexible is the INTERRUPT OUTPUT (a true high signal). This output can be programmed to provide 8 different output signals. They are: $10 \mathrm{~Hz}, 1 \mathrm{~Hz}$, once per minute, once per hour, once a day, once a week, once a month, and when a RAM/real time counter comparison occurs. To enable the output a one is written into the interrupt control register at the bit location corresponding to the desired output frequency (Figure 1). Once one or more bits have been set in the interrupt control register, the corresponding counter's rollover to its reset state will clock the interrupt status register and cause the interrupt output to go high. To reset the interrupt and to identify which frequency caused the interrupt, the interrupt status register is read. Reading this register places the contents of the status register on the data bus. The interrupting frequency will be identified by a one in the respective bit position. Removing the read will reset the interrupt.

The second interrupt is the STANDBY INTERRUPT (open drain output, active low). This interrupt occurs when enabled and when a RAM/real time counter comparison occurs. The STANDBY INTERRUPT is enabled by writing a one on the D0 line at address $16_{H}$ or disabled by writing a zero on the DO line. This interrupt is not triggered by the edge of the compare signal, but rather by the level. Thus if the compare is enabled when the STANDBY INTERRUPT is enabled, the interrupt will turn on immediately.

[^21]Functional Description (Continued)
table il. AdDress codes and functions

## Functional Description (Continued)

The comparator is a cascaded exclusive NOR. Its output is latched $61 \mu$ s after the rising edge of the 1 kHz clock signal (input to the ten thousandths of seconds counter). This allows the counter to ripple through before looking at the comparator. For operation at less than 4.0 V , the thousandths of seconds counter should not be included in a compare because of the possibility of having a ripple delay greater than $61 \mu \mathrm{~s}$. (For output timing see Interrupt Timing.)

## Power Down Mode

The POWER DOWN input is essentially a second chip select. It disables all inputs and outputs except for the STANDBY INTERRUPT. When this input is at a logical zero, the device will not respond to any external signals. It will, however, maintain timekeeping and turn on the STANDBY INTERRUPT if programmed to do so. (The programming must be done before the POWER DOWN input goes to a logical zero.) When switching $V_{D D}$ to the standby or power down mode, the POWER DOWN input should go to a logical zero at least $1 \mu \mathrm{~s}$ before $\mathrm{V}_{\mathrm{DD}}$ is switched. When switching $V_{D D}$ all other inputs must remain between $V_{S S}-0.3 \mathrm{~V}$ and $\mathrm{V}_{\mathrm{DD}}+0.3 \mathrm{~V}$. When restoring $V_{D D}$ to the normal operating mode, it is necessary to insure that all other inputs are at valid levels before switching the POWER DOWN input back to a logical one. These precautions are necessary to insure that no data is lost or altered when changing to or from the power down mode.

## Counter and RAM Resets; GO Command

The counters and RAM can be reset by writing all 1's(FF) at address $12_{\mathrm{H}}$ or $13_{\mathrm{H}}$ respectively.
A write pulse at address $15_{H}$ will reset the thousandths, hundredths, tenths, units, and tens of seconds counters. This GO command is used for precise starting of the clock. The data on the data bus is ignored during the write. If the seconds counter is at a value greater than 39 when the GO is issued, the minute counter will increment; otherwise the minute counter is unaffected. This command is not necessary to start the clock, but merely a convenient way to start precisely at a given minute.

## Status Bit

The status bit is provided to inform the user that the clock is in the process of rolling over when a counter is read. The status bit is set if this 1 kHz clock occurs during or after any counter read. This tells the user that the clock is rippling through the real time counter. Because the clock is
rippling, invalid data may be read from the counter. If the status bit is set following a counter read, the counter should be reread.

The status bit appears on D0 when address $14_{H}$ is read. All the other data lines will be zero. The bit is set when a logical one appears. This bit should be read every time a counter read or after a series of counter reads are done. The trailing edge of the read at address $14_{\mathrm{H}}$ will reset the status bit.

## Oscillator

The oscillator used is the standard Pierce parallel resonant oscillator. Externally, 2 capacitors, a $20 \mathrm{M} \Omega$ resistor and the crystal are required. The $20 \mathrm{M} \Omega$ resistor is connected between OSC IN and OSC OUT to bias the internal inverter in the linear region. For micropower crystals a resistor in series with the oscillator output may be necessary to insure the crystal is not overdriven. This resistor should be approximately $200 \mathrm{k} \Omega$. The capacitor values should be typically $20 \mathrm{pF}-25 \mathrm{pF}$. The crystal frequency is $32,768 \mathrm{~Hz}$.
The oscillator input can be externally driven, if desired. In this case the output should be left floating and the input levels should be within 0.3 V of the supplies.
A ground line or ground plane between pins 9 and 10 may be necessary to prevent interference of the oscillator by the A4 address.

## Control Lines

The $\overline{\text { READ }}, \overline{\text { WRITE, and CHIP SELECT }}$ signals are active low inputs. The READY signal is an open drain output. At the start of each read or write cycle the $\overline{R E A D Y}$ line (open drain) will pull low and will remain low until valid data from a chip read appears on the bus or data on the bus is latched in during a write. $\overline{\text { READ }}$ and WRITE must be accompanied by a CHIP SELECT (see Figures 3 and 4 for read and write cycle timing).
During a read or write, address bits must not change while chip select and control strobes are low.

## Test Mode

The test mode is merely a mode for production testing. It allows the counters to count at a higher than normal rate. In this mode the 32 kHz oscillator input is connected directly to the ten thousandths of seconds counter. The chip select and write lines must be low and the address must be held at $1 \mathrm{~F}_{\mathrm{H}}$.

Standby Interrupt Typical Characteristics

FIGURE 2. Typical Supply Current vs Supply Voltage During Power Down
Interrupt Timing $-40^{\circ} \mathrm{C} \leq \mathrm{T}_{\mathrm{A}} \leq 85^{\circ} \mathrm{C}, 4.5 \mathrm{~V} \leq \mathrm{V}_{\mathrm{DD}} \leq 5.5 \mathrm{~V}, \mathrm{~V}_{\mathrm{SS}}=0 \mathrm{~V}$

| Parameter |  | Min | Max | Units |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{t}_{\text {INTON }}$ | Status Register Clock to INTERRUPT OUTPUT (Pin 13) High (Note 1) |  | 5 | $\mu \mathrm{S}$ |
| $\mathrm{t}_{\text {SBYON }}$ | Compare Valid to STANDBY INTERRUPT (Pin 14) Low (Note 1) |  | 5 | $\mu \mathrm{S}$ |
| ${ }^{\text {I intoff }}$ | Trailing Edge of Status Register Read to INTERRUPT OUTPUT Low |  | 5 | $\mu \mathrm{S}$ |
| $t_{\text {SBYOFF }}$ | Trailing Edge of Write Cycle ( $\mathrm{DO}=0$; Address $=16_{\mathrm{H}}$ ) to $\overline{\text { STANDBY }}$ <br> INTERRUPT Off (High Impedance State) |  | 5 | $\mu \mathrm{S}$ |

Note 1: The status register clocks are: the corresponding counter's rollover to its reset state or the compare becoming valid. The compare becomes valid $61 \mu \mathrm{~s}$ after the $1 / 10,000$ of a second counter is clocked, if the real time counter data matches the RAM data.

Read Cycle Timing $-40^{\circ} \mathrm{C} \leq \mathrm{T}_{\mathrm{A}} \leq 85^{\circ} \mathrm{C}, 4.5 \mathrm{~V} \leq \mathrm{V}_{\mathrm{DD}} \leq 5.5 \mathrm{~V}, \mathrm{~V}_{\mathrm{SS}}=0 \mathrm{~V}$

|  | Parameter | Min | Max | Units |
| :---: | :---: | :---: | :---: | :---: |
| $t_{\text {AR }}$ | Address Bus Valid to Read Strobe | 100 |  | ns |
| $t_{\text {cSR }}$ | Chip Select to Read Strobe | 0 |  | ns |
| $t_{\text {RRY }}$ | Read Strobe to Ready Strobe |  | 150 | ns |
| $\mathrm{t}_{\mathrm{RYD}}$ | Ready Strobe to Data Valid |  | 800 | ns |
| $t_{\text {AD }}$ | Address Bus Valid to Data Valid |  | 1050 | ns |
| $t_{\text {RH }}$ | Data Hold Time From Trailing Edge of Read Strobe | 0 |  | ns |
| $t_{H Z}$ | Trailing Edge of Read Strobe to TRI-STATE Mode |  | 250 | ns |
| $t_{\text {RYH }}$ | Read Hold Time after Ready Strobe | 0 |  | ns |
| $t_{\text {RA }}$ | Address Bus Hold Time from Trailing Edge of Read Strobe | 50 |  | ns |
| $t_{\text {RYDV }}$ | Rising Edge of Ready to Data Valid |  | 100 | ns |

Write Cycle Timing $-40^{\circ} \mathrm{C} \leq \mathrm{T}_{\mathrm{A}} \leq 85^{\circ} \mathrm{C}, 4.5 \mathrm{~V} \leq \mathrm{V}_{\mathrm{DD}} \leq 5.5 \mathrm{~V}, \mathrm{~V}_{\mathrm{SS}}=0 \mathrm{~V}$

Note 3: If data changes while $\overline{\mathrm{CS}}$ and $\overline{\mathrm{WR}}$ are low, then they must remain coincident for 1050 ns after the data change to ensure a valid write.
Data bus loading is 100 pF .
Ready output loading is 50 pF and $\mathbf{3} \mathbf{k} \Omega$ pull-up.
Input and output AC timing levels:
Logical one $=2.0 \mathrm{~V}$
Logical zero $=0.8 \mathrm{~V}$

## Read and Write Cycle Timing Diagrams

## MM58174A Microprocessor-Compatible Real-Time Clock

## General Description

The MM58174A is a low-threshold metal-gate CMOS circuit that functions as a real-time clock and calendar in bus-oriented microprocessor systems. The device includes an interrupt timer which may be programmed to one of three times. Time-keeping is maintained down to 2.2V to allow low power standby battery operation. The timebase is generated from a 32768 Hz crystal-controlled oscillator.

## Features

- Microprocessor compatible
- Tenths of seconds, seconds, tens of seconds, minutes, tens of minutes, day of week, days, tens of days, months, tens of months, independent registers
- Automatic leap year calculation
- internal pull-ups to safeguard data

■ Protection for read during data changing

- Independent interrupt system with open drain output
- TTL compatible
- Low power standby operation ( $2.2 \mathrm{~V}, 10 \mu \mathrm{~A}$ )
- Low cost internally biased oscillator
- Low cost 16 -pin dual-in-line package
- Available for commercial and military temperature ranges

## Applications

- Point-of-sale terminals
- Word processors
- Teller terminals
- Event recorders
- Microprocessor-controlled instrumentation
- Microprocessor time clock
- TVIVCR reprogramming
- Intelligent telephone

## Functional Description

The MM58174 is a microprocessor bus-oriented real-time clock. The circuit includes addressable real-time counters for tenths of seconds through months and a write only register for leap year calculation. The counters are arranged as bytes of four bits each. When addressed a byte will appear on the data I/O bus so that each word can be accessed independently. If any byte does not contain four bits (e.g. days of the week uses only 3 bits), the unused bits will be unrecognized during a write operation and tied to $V_{S S}$ during a read operation.

The addressable reset latch causes the pre-scaler, tenths of seconds, seconds, and tens of seconds to be held in a reset condition. If a register is updated during a read operation the I/O data is prevented from updating and a subsequent read will return the illegal b.c.d. code '1111'. The interrupt timer may be programmed for intervals of 0.5 second, 5 seconds, or 60 seconds and may be coded as a single or repeated operation. The open drain interrupt output is pulled to $V_{S S}$ when the timer times out and reading the interrupt register provides the internal selected information.

## Circuit Description

The block diagram shown in Figure 1 shows the structure of the CMOS clock chip. A 16 -pin DIL package is used.

## Crystal Oscillator

This consists of a CMOS inverter/amplifier with on-chip bias resistor and capacitors. A single 6-36 pF trimmer is all that is required to fine tune the crystal (see Figure 2). However, for improved stability, some crystals may require a capacitor of typical value 20 pF to be added between pin 14 and ground. The output of the oscillator is blocked by the start/stop F/F.

## Non-Integer Divider

This counter divides the incoming $32,768 \mathrm{~Hz}$ frequency by $15 / 16$ down to $30,720 \mathrm{~Hz}$.

## Fixed Divider (512)

This is a standard 9-stage binary ripple counter. Output frequency is 60 Hz . This counter is reset to zero by start/ stop F/F.

## Fixed Divider (6)

This is a 3 -stage Johnson counter with a 10 Hz output signal. This counter is reset to zero state by the start/stop F/F.

## Synchronization Stage

Both 10 Hz and $32,768 \mathrm{~Hz}$ clocks are fed into this section. It is used to generate a pulse of $15.25 \mu \mathrm{~s}$ width on the rising edge of each 10 Hz pulse.
This pulse is used to increment all the seconds, minutes, hours, days, months, and year counter and also to set the data changed F/F.

## Data Changed F/F

This is set by the rising edge of each 10 Hz pulse to indicate that the clock value has changed since the last read operation. It is reset by any clock read command.

## Connection Diagram

Order Number MM58174AN
See NS Package N16E
The flip-flop sets all data bus bits to a " 1 " during RD time indicating that a register has been updated. This transient condition may occur at the end of the Read Data strobe. Hence, invalid data may still be read from the clock, if the strobe width was less than $3 \mu \mathrm{~s}$.

The possibility may be overcome by implementing a further read of the tenths of seconds register at the end of every series of reads (starting with a read at the tenths of seconds register) and checking for unchanged data.

## Seconds Counters

There are three counters for Seconds:
a) tenths of seconds
b) units of seconds
c) tens of seconds

The outputs of all three counters can be separately multiplexed on to the command 4-bit output bus. Table 1 shows the address decoding for each counter. All three counters are reset to zero by the start/stop F/F.

## Minutes Counters

There are two Minutes counters:
a) units of minutes
b) tens of minutes

Both counters are parallel loaded with data from the 4 -bit input bus when addressed by the microprocessor and a Write Data Strobe pulse given. Similarly, the output of both counters can be read separately onto the common 4 -bit output bus (Table 1).

## Hours Counters

There are two Hours counters which will count in a 24 hour mode:
a) units of hours
b) tens of hours

Both counters have identical parallel load and read multiplex features to the Minutes counters.

## Seven Day Counter

There is a 7 -state counter which increments every 24 hours. It will have identical parallel load and read multiplex capabilities to the Minutes and Hours counters. The counter counts cyclically from 1-7.

Figure 2. Crystal Oscillator

## Days Counter

There are two Days counters:
a) units of days
b) tens of days

The Days counters will count up to $28,29,30$, or 31 days depending on the state of the Months counters and the Years Status Register. Days counters have parallel load and read multiplex capabilities.

## Months Counters

There are two Months counters:
a) units of months
b) tens of months

The Months counters have parallel load and read multiplex capabilities.

## Years Status Register
