## A Corporate Dedication to Quality and Reliability

National Semiconductor is an industry leader in the manufacture of high quality, high reliability integrated circuits. We have been the leading proponent of driving down IC defects and extending product lifetimes. From raw material through product design, manufacturing and shipping, our quality and reliability is second to none.
We are proud of our success . . . it sets a standard for others to achieve. Yet, our quest for perfection is ongoing so that you, our customer, can continue to rely on National Semiconductor Corporation to produce high quality products for your design systems.

Charles E. Sporck
President, Chief Executive Officer National Semiconductor Corporation

## Wir fühlen uns zu Qualität und Zuverlässigkeit verpflichtet

National Semiconductor Corporation ist führend bei der Herstellung von integrierten Schaltungen hoher Qualität und hoher Zuverlässigkeit. National Semiconductor war schon immer Vorreiter, wenn es galt, die Zahl von IC Ausfällen zu verringern und die Lebensdauern von Produkten zu verbessern. Vom Rohmaterial über Entwurf und Herstellung bis zur Auslieferung, die Qualität und die Zuverlässigkeit der Produkte von National Semiconductor sind unübertroffen.
Wir sind stolz auf unseren Erfolg, der Standards setzt, die für andere erstrebenswert sind. Auch ihre Ansprüche steigen ständig. Sie als unser Kunde können sich auch weiterhin auf National Semiconductor verlassen.

## La Qualité et La Fiabilité: <br> Une Vocation Commune Chez National Semiconductor Corporation

National Semiconductor Corporation est un des leaders industriels qui fabrique des circuits intégrés d'une très grande qualité et d'une fiabilité exceptionelle. National a été le premier à vouloir faire chuter le nombre de circuits intégrés défectueux et a augmenter la durée de vie des produits. Depuis les matières premières, en passant par la conception du produit sa fabrication et son expédition, partout la qualité et la fiabilité chez National sont sans équivalents.
Nous sommes fiers de notre succès et le standard ainsi défini devrait devenir l'objectif à atteindre par les autres sociétés. Et nous continuons à vouloir faire progresser notre recherche de la perfection; il en résulte que vous, qui êtes notre client, pouvez toujours faire confiance à National Semiconductor Corporation, en produisànt des systèmes d'une très grande qualité standard.

## Un Impegno Societario di Qualità e Affidabilità

National Semiconductor Corporation è un'industria al vertice nella costruzione di circuiti integrati di altà qualità ed affidabilità. National è stata il principale promotore per l'abbattimento della difettosità dei circuiti integrati e per l'allungamento della vita dei prodotti. Dal materiale grezzo attraverso tutte le fasi di progettazione, costruzione e spedizione, la qualità e affidabilità National non è seconda a nessuno.

Noi siamo orgogliosi del nostro successo che fissa per gli altri un traguardo da raggiungere. Il nostro desiderio di perfezione è d'altra parte illimitato e pertanto tu, nostro cliente, puoi continuare ad affidarti a National Semiconductor Corporation per la produzione dei tuoi sistemi con elevati livelli di qualità.

Charles E. Sporck
President, Chief Executive Officer
National Semiconductor Corporation

## LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

NationalSemiconductor Corporation 2900 Semiconductor Drive, P.O. Box 58090, Santa Clara, California 95052-8090 (408) 721-5000 TWX (910) 339-9240
National does not assume any responsibility for use of any circuitry described, no circuit patent licenses are implied, and National reserves the right, at any time without notice, to change said circuitry or specifications.

## Product Status Definitions

Definition of Terms

| Data Sheet Identification | Product Status | Definition |
| :--- | :--- | :--- |
| Advance Information | Formative or <br> In Design | This data sheet contains the design specifications for product <br> development. Specifications may change in any manner without notice. |
| Proliminary | First <br> Production | This data sheet contains preliminary data, and supplementary data will <br> be published at a later date. National Semiconductor Corporation <br> reserves the right to make changes at any time without notice in order <br> to improve design and supply the best possible product. |
| No <br> Identification <br> Noted | Full <br> This data sheet contains final specifications. National Semiconductor <br> Corporation reserves the right to make changes at any time without <br> notice in order to improve design and supply the best possible product. |  |

National Semiconductor Corporation reserves the right to make changes without further notice to any products herein to improve reliability, function or design. National does not assume any liability arising out of the application or use of any product or circuit described herein; neither does it convey any license under its patent rights, nor the rights of others.

## Guide to Bipolar Logic Device Families

Since the introduction of the first saturating logic bipolar integrated circuit family (DM54/DM74), there have been many developments in the process and manufacturing technologies as well as circuit design techniques which have produced new generations (families) of bipolar logic devices. Each generation had advantages and disadvantages over the previous generations. Today National provides seven bipolar logic families.
TTL
(DM54/DM74)
Low Power TTL
Low Power Schottky
Advanced Low Power Schottky Schottky
Advanced Schottky
(DM54LS/DM74LS)
(DM54ALS/DM74ALS)
(DM54S/DM74S)
FAST
(DM54AS/DM74AS)

## TTL LOGIC (DM54/DM74) and (54xx)

TTL logic was the first saturating logic integrated circuit family introduced, thus setting the standard for all the future families. It offers a combination of speed, power consumption, output source and sink capabilities suitable for most applications. This family offers the greatest variety of logic functions. The basic gate (see Figure 1) features a multipleemitter input configuration for fast switching speeds, active pull-up output to provide a low driving source impedance which also improves noise margin and device speed. Typical device power dissipation is 10 mW per gate and the typical propagation delay is 10 ns when driving a 15 $\mathrm{pF} / 400 \Omega$ load.

## LOW POWER TTL (DM54L)

The low power family has essentially the same circuit configuration as the TTL devices. The resistor values, however, are increased by nearly tenfold, which results in tremendous reduction of power dissipation to less than $1 / 10$ of the TTL family. Because of this reduction of power, the device speed

is sacrificed. The propagation delays are increased threefold. These devices have a typical power dissipation of 1 mW per gate and typical propagation delay of 33 ns , making this family ideal for applications where power consumption and heat dissipation are the critical parameters.

## LOW POWER SCHOTTKY (DM54LS/DM74LS and 54LS)

The low power Schottky family features a combined fivefold reduction in current and power when compared to the TTL family. Gold doping commonly used in the TTL devices reduces switching times at the expense of current gain. The LS process overcomes this limitation by using a surface barrier diode (Schottky diode) in the baker clamp configuration between the base and collector junction of the transistor. In this way, the transistor is never fully saturated and recovers quickly when base drive is interrupted. Using shallower diffusion and soft-saturating Schottky diode clamped transistors, higher current gains and faster turn-on times are obtained. The National LS circuits and a majority of the former Fairchild LS circuits do not use the multi-emitter inputs. They use diode-transistor inputs which are faster and give increased input breakdown voltage; the input threshold is $\sim 0.1 \mathrm{~V}$ lower than TTL. A few of the former Fairchild LS circuits use the traditional emitter inputs and thus have input breakdown ratings of 5.5 V . These circuits are the open-collector gate types 'LS03, 'LS05, 'LS22 and 'LS136; flip-flop types 'LS74, 'LS109, 'LS112 and 'LS113; and the clock inputs of the 'LS490. Another commonly used input is the vertical substrate PNP transistor. In addition to fast switching, it exhibits very high impedance at both the high and low input states, and the transistor's current gain ( $\beta$ ) significantly reduces input loading and provides better output performance. The output structure is also modified with a Darlington transistor pair to increase speed and improve drive capability. An active pull-down transistor (Q3) is incorporated to

TL/F/5534-7
FIGURE 2. DM54L00
yield a symmetrical transfer characteristic (squaring network). This family achieves circuit performance exceeding the standard TTL family at fractions of its power consumption. The typical device power dissipation is 2 mW per gate and typical propagation delay is 10 ns while driving a $15 \mathrm{pF} /$ $2 \mathrm{k} \Omega$ load.

## SCHOTTKY (DM54S/DM74S)

This family features the high switching speed of unsaturated bipolar emitter-coupled logic, but consumes more power than standard TTL devices. To achieve this high speed, the Schottky barrier diode is incorporated as a clamp to divert the excess base current and to prevent the transistor from reaching deep saturation. The Schottky gate input and internal circuitry resemble the standard TTL gate except the resistor values are about one-half the TTL value. The output section has a Darlington transistor pair for pull-up and an active pull-down squaring network. This family has power dissipation of 20 mW per gate and propagation delays three times as fast as TTL devices with the average time of 3 ns while driving $15 \mathrm{pF} / 280 \Omega$ load.

## ADVANCED LOW POWER SCHOTTKY (DM54ALS/DM74ALS)

The advanced low power Schottky family is one of the most advanced TTL families. It delivers twice the data handling efficiency and still provides up to $50 \%$ reduction in power consumption compared to the LS family. This is possible because of a new fabrication process where components are isolated by a selectively grown thick-oxide rather than the P-N junction used in conventional processes. This refined process, coupled with improved circuit design techniques, yields smaller component geometries, shallower diffusions, and lower junction capacitances. This enables the devices to have increased $\mathrm{f}_{\mathrm{T}}$ in excess of 5 GHz and improved switching speeds by a factor of two, while offering much lower operating currents.

TL/F/5534-3
FIGURE 3. DM54LS00/DM74LS00

In addition to the pin-to-pin compatibility of the ALS family, a large number of MSI and LSI functions are introduced in the high density 24 -pin 300 mil DIP. These devices offer the designers greater cost effectiveness with the advantages of reduced component count, reduced circuit board real-estate, increased functional capabilities per device and improved speed-power perfomance.
The basic ALS gate schematic is quite similar to the LS gate. It consists of either the PNP transistor or the diode inputs, Darlington transistor pair pull-up and active pulldown (squaring network) at the output. Since the shallower diffusions and thinner oxides will cause ALS devices to be more susceptible to damage from electro-static discharge, additional protection via a base-emitter shorted transistor is included at the input for rapid discharge of high voltage static electricity. Furthermore, the inputs and outputs are clamped by Schottky diodes to prevent them from swinging excessively below ground level. A buried $\mathrm{N}^{+}$guard ring around all input and output structures prevents crosstalk. The ALS family has a typical power dissipation of 1 mW per gate and typical propagation delay time of 4 ns into a $50 \mathrm{pF} / 2 \mathrm{k} \Omega$ load.

## ADVANCED SCHOTTKY (DM54AS/DM74AS)

This family of devices is designed to meet the needs of the system designers who require the ultimate in speed. Utilizing Schottky barrier diode clamped transistors with shallower diffusions and advanced oxide-isolation fabrication techniques, the AS family achieves the fastest propagation delay that bipolar technology can offer. The AS family has virtually the same circuit configuration as the ALS family. It has PNP transistor or diode inputs with electrostatic protection base-emitter shorted transistors. The output totem-pole consists of a Darlington pair transistor pull-up and an active

FIGURE 3a. 54/74LSOO
pull-down squaring network. The inputs and outputs are Schottky clamped to attenuate critical transmission line reflections. In addition, the circuit contains the "Miller Killer" network at the output section to improve output rise time and reduce power consumption during switching at high repetition rates. The AS family yields typical power dissipation of 7 mW per gate and propagation delay time of 1.5 ns when driving a $50 \mathrm{pF} / 2 \mathrm{k} \Omega$ load.

## FAST® TECHNOLOGY

FAST (Fairchild Advanced Schottky TTL) circuits are made with the advanced isoplanar II process, which produces transistors with very high, well-controlled switching speeds, extremely small parasitic capacitances and $\mathrm{f}_{\mathrm{T}}$ in excess of 5 GHz . Isoplanar is an established National process, used for years in the manufacture of bipolar memories. CMOS, subnanosecond ECL and ${ }^{3}$ LTM $^{T M}$ (Isoplanar Integrated Injection Logic) LSI devices.
In the isoplanar process, components are isolated by a selectively grown thick oxide rather than the $\mathrm{p}^{+}$isolation region used in the planar process. Since this oxide needs no separation from the base-collector regions, component and

TL/F/5534-4
FIGURE 4. DM54S00/DM74S00
chip sizes are substantially reduced. The base and emitter ends terminate in the oxide wall; masks can thus overlap the device area into the isolation oxide. This overlap feature eliminates the extremely close tolerances normally required for base and emitter masking, and the standard photolithographic processes can be used.

## SELECTING A FAMILY

Two factors shoud be considered when choosing a logic family for application, speed and power consumption. New logic families were created to improve the speed or lower the power consumption of the previous families. The following tables rate each family.

| Speed |  |  | Power Consumption |  |
| :---: | :---: | :---: | :---: | :---: |
| Fastest | AS/F | Low | L |  |
|  | S |  | ALS |  |

## ALS／AS IC Device Testing

Understanding the intent and practice of IC device testing is vital to insuring both the quality and proper usage of inte－ grated circuits．All National Semiconductor data sheets list the $A C$ and DC parameters with min and／or max limits， along with forcing functions．Understanding when a part fails the limit，and which forcing functions are really tighter， is critical when determining if an IC device is good or bad．
All of National＇s databook parameters are defined and guar－ anteed for＂worst－case testing．＂Input loading currents（fan－ in ）are tested at the input and $\mathrm{V}_{\mathrm{CC}}$ levels that most increase that loading，while the output drive capability（fan－out）is tested at the input and $V_{C C}$ levels that most decrease that capability．I ICC is tested with the input conditions and $V_{C C}$ level that yield the greatest ICC value，and $V_{\text {CLAMP }}$ is tested such that the negative voltage is maximized for the given clamp current．The fan－in and fan－out specs are contained in the $I_{I_{H}}, I_{O H}, I_{I L}$ and $I_{O L}$ values．To guarantee these fan－in and fan－out limits at 10 ，the $\mathrm{l}_{\text {OL }}$ must be at least 10 times the $I_{I L}$ and the $I_{O H}$ must be at least 10 times the $I_{I H}$ ．Be aware that the fan－in and fan－out specifications are valid only within a given device family．The standard input loading and output drives are shown in Table I．
Notice that the $\mathrm{I}_{\mathrm{OL}}$ is at least 10 times the $\mathrm{I}_{I L}$ and that the $\mathrm{l}_{\mathrm{OH}}$ is greater than 10 times the $\mathrm{I}_{\mathrm{IH}}$ ．Also notice that these are＂standard＂drive and load currents for single sink out－ puts and inputs．Certain devices may have multiple load in－ puts where the input line goes to several input structures and has，say， 2 or 3 times the normal $l_{I L}$ and $I_{I H}$ loading．

Certain other devices will have＂triple sink＂outputs that can drive 3 times the standard $\mathrm{I}_{\mathrm{OL}}$ and $\mathrm{I}_{\mathrm{OH}}$ currents．These de－ vices are generally bus drivers，or drivers intended to drive highly capacitive loads．Finally，there are certain devices that have PNP inputs that reduce the I IL loading to typically $-200 \mu \mathrm{~A}$ ，thus allowing an increased DC fan－in of 20 ．One must therefore be careful when interfacing many different types of devices，even in the same family，and not simply go the＂fan－out of 10＂rule．
When dealing with any kind of device specification，it is im－ portant to note that there exists a pair of test conditions that define that test：the forcing function and the limit．Forcing functions appear under the column labeled＂Conditions＂ and define the external operating constraints placed upon the device tested．The actual test limit defines how well the device responds to these constraints．For example，take the parameter $\mathrm{V}_{\mathrm{OH}(\mathrm{min})}$ for the DM74LSO0．It is tested at $\mathrm{V}_{\mathrm{CC}(\text { min })}=4.75 \mathrm{~V}$ commercial，using an $\mathrm{l}_{\mathrm{OH}}=-400 \mu \mathrm{~A}$ ．If we required an $\mathrm{I}_{\mathrm{OH}}=-800 \mu \mathrm{~A}$ ，this would be a＂tighter＂ test，as the output voltage drops with increased $\mathrm{I}_{\mathrm{OH}}$ ．Hence， a device that would pass the $-800 \mu \mathrm{~A} \mathrm{I}_{\mathrm{OH}}$ would also pass the $-400 \mu \mathrm{~A} \mathrm{l}_{\mathrm{OH}}$ ，but not necessarily the other way around． Futhermore，$V_{O H}$ tracks with $V_{C C}$ ，which is why $V_{C C(m i n)}$ is the worst－case testing，and not $\mathrm{V}_{\mathrm{CC}(\text { max })}$ ．Finally，forcing in－ puts to threshold represents the most difficult testing be－ cause this puts those inputs as close as possible to the actual switching point and guarantees that the device will meet the $\mathrm{V}_{\mathrm{IH}} / \mathrm{V}_{\mathrm{IL}}$ spec．

TABLE I．Fan－In／Fan－Out

Tables II and III show the "direction" of the looser/tighter testing for most common DC parameters. Notice that one can tighten either the forcing function or the limit, or both. Tightening either one is sufficient to insure a tighter test. Also notice the difference between max and min limits. For los (double-ended limits), even though -20 mA is more positive than -100 mA , and is mathematically the max limit,
the magnitude of the number is the determining factor when deciding which is the max limit. The negative sign simply implies the direction that the current is going, with a negative current leaving the device, and a positive current entering the device. Table Il shows the direction of tighter forcing functions, while Table III shows the direction of tighter limits.

TABLE II. Looser/Tighter Forcing Functions Example: DM74ALS00

| Condition | Test | Looser | Nominal | Tighter | Units |
| :--- | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{I}_{\mathrm{IK}}$ | $\mathrm{V}_{\mathrm{IK}}$ | -17 | -18 | -19 | mA |
| $\mathrm{I}_{\mathrm{OH}}$ | $\mathrm{V}_{\mathrm{OH}}$ | -350 | -400 | -450 | $\mu \mathrm{~A}$ |
| $\mathrm{I}_{\mathrm{OL}}$ | $\mathrm{V}_{\mathrm{OL}}$ | 7 | 8 | 9 | mA |
| $\mathrm{~V}_{\mathrm{I}}$ | $\mathrm{I}_{\mathrm{I}}$ | 6.5 | 7 | 7.5 | V |
| $\mathrm{~V}_{\mathrm{IH}}$ | $\mathrm{I}_{\mathrm{IH}}$ | 2.6 | 2.7 | 2.8 | V |
| $\mathrm{~V}_{\mathrm{IL}}$ | $\mathrm{I}_{\mathrm{IL}}$ | 0.5 | 0.4 | 0.3 | V |
| $\mathrm{~V}_{\mathrm{O}}$ | 3 | 2.25 | 2 | V |  |
| $\mathrm{~V}_{\mathrm{CC}}$ | $\mathrm{I}_{\mathrm{OS}}$ | 3 | 5.5 | 6.0 | V |

TABLE III. Looser/Tighter Test Limits Example: DM74ALS00

| Parameter | Looser | Nominal | Tighter | Units |
| :--- | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\mathrm{IH}(\min )}$ | 2.1 | 2.0 | 1.9 | V |
| $\mathrm{~V}_{\mathrm{IL}(\max )}$ | 0.7 | 0.8 | 0.9 | V |
| $\mathrm{~V}_{\mathrm{IK}(\max )}$ | -1.6 | -1.5 | -1.4 | V |
| $\mathrm{~V}_{\mathrm{OH}(\min )}$ | 2.6 | 2.7 | 2.8 | V |
| $\mathrm{~V}_{\mathrm{OL}(\max )}$ | 0.6 | 0.5 | 0.4 | V |
| $\mathrm{I}_{(\text {min })}$ | 125 | 100 | 75 | $\mu \mathrm{~A}$ |
| $\mathrm{I}_{\mathrm{IH}(\max )}$ | 25 | 20 | 15 | $\mu \mathrm{~A}$ |
| $\mathrm{IIL}_{\text {(max })}$ | -125 | -100 | -75 | $\mu \mathrm{~A}$ |
| $\mathrm{I}_{\mathrm{OS}(\max )}$ | -120 | -112 | -100 | mA |
| $\mathrm{I}_{\mathrm{OS}(\min )}$ | -25 | -30 | -35 | mA |
| $\mathrm{I}_{\mathrm{CCH}(\max )}$ | 1.0 | 0.85 | 0.7 | mA |
| $\mathrm{I}_{\mathrm{CCL}(\max )}$ | 3.5 | 3 | 2.5 | mA |

Following are the test set-ups that are used to test the DC parametrics. In each case, the gate connection, equivalent circuit schematic and resultant voltage/current plot are shown.
The indicated graphs are typical of LS products and are similiar to other bipolar logic families. The schematics shown are for single inversion devices and represent generalized circuits.

## OUTPUT VOLTAGE LOW LEVEL (VoL)

Both inputs are connected to logic " 1 " values (assuming an inverting gate) and forced at the $\mathrm{V}_{1 \mathrm{H}}$ specs. $\mathrm{V}_{\mathrm{CC}}$ minimum is used, and $\mathrm{I}_{\mathrm{OL}}$ is forced on the output. The resulting $\mathrm{V}_{\mathrm{OL}}$ is

TL/F/10621-3

TL/F/10621-5
measured. For typical LS products, the military and commercial test points are indicated on the $V_{O L}$ vs loL graph. In each case, the device must not exceed the $V_{\text {OL }}$ spec when the lol current is being forced.

## OUTPUT VOLTAGE HIGH LEVEL (VOH)

One input is tied high (any value above 2.0 V ) and the other input is forced at the $\mathrm{V}_{\mathrm{IL}}$ threshold (assuming a single inversion gate). The minimum $V_{C C}$ value is used. Each input is tested independently and the $\mathrm{I}_{\mathrm{OH}}$ current is forced. The resulting $\mathrm{V}_{\mathrm{OH}}$ is measured. The $\mathrm{VOH}_{\mathrm{OH}} \mathrm{vs} \mathrm{lOH}_{\mathrm{OH}}$ graph shows the military and commercial $\mathrm{V}_{\mathrm{OH}} / \mathrm{I}_{\mathrm{OH}}$ test points for standard LS products.

## INPUT CURRENT HIGH LEVEL ( $I_{H}$ )

$I_{I H}$ tests the input leakage in the high state. For MET, diode, and PNP input, the test set-up consists of all inputs except the one under test tied high (greater than $\mathrm{V}_{\mathrm{IH}}$ ). The remaining input has the $\mathrm{V}_{\mathrm{IH}}$ value forced upon it, and the resultant $\mathrm{I}_{\mathbb{H}}$ is measured. This test checks for emitter-to-collector inverse transistor action for MET inputs, and reverse bias leakage for diode and PNP inputs.
For MET inputs, there is also an additional set-up for $\mathrm{I}_{\mathrm{I}}$ testing that checks for emitter-to-emitter transistor action. This is done with all the other inputs tied to ground.

## MAXIMUM INPUT CURRENT ( 1 )

$I_{1}$ or $B V_{I N}$ testing is the same as the emitter-to-collector leakage test ( $l_{H}$ ) and guarantees that the input will not pass more than the specified current at the stated specification ( $100 \mu \mathrm{~A}$ at 7 V for LS).

TL/F/10621-7

TL/F/10621-9

## INPUT CURRENT LOW LEVEL ( $\mathrm{I}_{\mathrm{L}}$ )

One input at a time is tested with the other inputs tied to a solid " 1 " value. $\mathrm{V}_{\mathrm{CC}}$ is set to the maximum value and the $V_{I L}$ value is forced. $I_{L L}$ is then measured.

$$
\begin{aligned}
& I_{I L}=\frac{\left[V_{C C}-\left(V_{I L}+V_{B E}\right)\right]}{R 1} \text { Standard Inputs } \\
& I_{I L}=\frac{\left[V_{C C}-\left(V_{I L}+V_{S H}\right)\right]}{R 1} \text { Diode Inputs } \\
& I_{I L}=\frac{\left[V_{C C}-\left(V_{I L}+V_{B E}\right)\right]}{R 1 \times \beta} \text { PNP Inputs }
\end{aligned}
$$

$I_{I L}$ is intended to measure the value of the base pull-up resistor on the input, and to guarantee the maximum input load an IC presents.

TL/F/10621-10

TL/F/10621-11

## OUTPUT SHORT CIRCUIT CURRENT (los)

los is measured with $\mathrm{V}_{\mathrm{CC}(\max )}$ and the V forced on the output while it is in the high state. The resultant current is measured. The purpose of this is to check the los resistor that forms the Darlington's collector pull-up. This parameter is important as it reflects both the maximum current the device will draw and the maximum drive it will provide when it is switching from low to high.
Caution must be taken when measuring TTL, LS and S outputs as the power dissipated on the die will be substantial. los shorts should not be maintained in excess of one second or damage to the device may result.

TL/F/10621-13

LOGIC "0"

TL/F/10621-15

TL/F/10621-17

## SUPPLY CURRENT HIGH LEVEL (Іссн) AND SUPPLY CURRENT LOW LEVEL (Iccl)

Both $I_{C C H}$ and $I_{C C L}$ are tested using the $V_{C C}$ maximum value. The inputs are set to the values necessary to achieve the output in the desired state. All outputs are left open, neither sourcing nor sinking current. The goal of this test is to guarantee the maximum quiescent operating power that the device will draw.

TL/F/10621-16

TL/F/10621-18

INPUT CLAMP VOLTAGE (VIC OR VIK)
$V_{\text {CLAMP }}\left(V_{\text {IK }}\right)$ is measured with all but one input tied high and the $\mathbb{I}_{K}$ current forced on the remaining input. $V_{C C}$ is set to the minimum and the $\mathrm{V}_{\mathrm{IK}}$ voltage is measured.

OUTPUT TRI-STATE CURRENT HIGH LEVEL (lozh) AND OUTPUT TRI-STATE CURRENT LOW LEVEL (IOZL)
TRI-STATE ${ }^{\text {® }}$ I $_{\text {SINK }}$ and ISOURCE are measured with the output control input tied to the appropriate threshold value (usually $\mathrm{V}_{\mathrm{IL}}=0.8 \mathrm{~V}$ ) and with $\mathrm{V}_{\mathrm{CC}(\max )}$. This is to insure that

the output will have the greatest drive capability and the TRI-STATE control can effectively "turn off" the output under these conditions.
TRI-STATE ISINK: Output is set in the high state and then TRI-STATE mode. $\mathrm{V}_{\text {OZL }}=0.4 \mathrm{~V}$ is then applied. The current drawn out of the device is then measured.

TRI-STATE ISOurce: Output is set in the low state and then TRI-STATE mode. $\mathrm{V}_{\text {OZH }}=2.7 \mathrm{~V}$ is then applied. The current drawn into the device is then measured.

TL/F/10621-23

## HIGH LEVEL OUTPUT CURRENT (OPEN-COLLECTOR DEVICES ONLY)

$I_{\text {CEX }}$ is tested with the output in the high state. $V_{C C}$ is set to 5.0 V and the specified voltage ( 5.5 V for LS ) is applied to the output. The inputs are at the threshold values $(0.8 \mathrm{~V}$ and 2.0 V , depending upon the logic to put output in the high state) and the resulting ICEX leakage current is measured.

## AC SWITCHING CHARACTERISTICS

The AC switching characteristics are generally measured in units of time (commonly in nanoseconds), and define how long it takes for the signal to propagate from the input to the output. The definitions used in determining the pass/fail status of each limit are not the same for AC as they are for DC. The distinction lies in the fact that for DC operation there exists one characteristic V-I curve on which the device must operate. Devices are good if they operate on the correct side of the limit, and bad if they operate on the wrong side of the limit. When dealing with certain AC parameters ( $f_{\text {max }}, \mathrm{t}_{\text {SET-UP, }} \mathrm{t}_{\text {hold }}, \mathrm{t}_{\text {RELEASE, }} \mathrm{t}_{\text {PW }}$ ), the device can, and usually does, operate on both sides of the databook limit. The limit really implies a boundary that all devices are guaranteed to exceed. Depending upon the parameter, the device will either operate at all values above and some below the limit, or it will operate at all values below and some above the limit. In each case, the device is only guaranteed to operate for all values on one side of the limit. Although the device will also operate beyond the limit, it is not guaranteed to. Furthermore, device operation beyond the limit is not considered a failure. For instance, take the f MAX parameter with a min limit of 25 MHz . All devices are guaranteed to operate at all frequencies below 25 MHz and will operate in excess of 25 MHz , although this is not guaranteed. Now, take the example of tSET-UP with a minimum limit of 25 ns . All of the devices are guaranteed to operate with a set-up time of 25 ns and longer, and will operate with set-up times below 25 ns , although this is not guaranteed either. Be aware that both of these specifications are listed in the minimum column in the databook, but the interpretation of what is failing differs significantly.
Propagation delays (called prop delays and denoted by the symbols $\mathrm{t}_{\mathrm{PHL}}$ and $\mathrm{t}_{\mathrm{PLH}}$ ) are specified as maximum limits, and guarantee the maximum time one must wait to insure that the correct data has appeared at the device's output. Each propagation delay is specified from one input to one output only.
Input set-up and hold times (including treLEASE) specify how long one input must be stable at a particular logic level prior to an action occurring at another input. For example, take the DM54/74LS74 positive-edge-triggered D flip-flop. The "set-up 1" specification defines how long a logic " 1 " must be present and stable at the DATA input prior to the positive edge of the CLOCK to insure that the device will recognize that data as a " 1 ". There also exists a "hold 1" specification which specifies how long a logic " 1 " must be held after the active edge of CLOCK for the device to recognize that logic " 1 ". Both the set-up and hold times must always be met or the device will not necessarily bring in the proper data. Set-up times are generally' positive, while hold
times may be either positive or negative, usually negative. The meaning of a negative hold time is that the data may be removed from the input prior to the active edge of CLOCK, and the CLOCK will still bring in the desired data. Set-up and hold times are specified as minimum values, since this defines the minimum time data must be stable prior to any change at the CLOCK input. Removing the data sooner than the minimum time may cause improper action on the part of the device.
$t_{\text {RELEASE }}$ is specified on devices where there is an input that must be set inactive prior to the active edge of CLOCK. Such inputs are usually overriding inputs like CLEAR and PRESET. With CLEAR active, it will prevent the device from switching on the CLOCK signal. $t_{\text {RELEASE }}$ is defined as the time it takes for the CLEAR input to "release" the device for clocking action, and is specified as a minimum. This represents the maximum delay required between CLEAR going inactive and the active edge of CLOCK to insure proper device operation.
All devices that have a CLOCK input also have a specification that defines the maximum speed that the CLOCK can be driven, called $\mathrm{f}_{\text {MAX }}$. This specification is defined as a minimum specification and states that all of the devices will
be able to operate at frequencies up to 25 MHz . For the DM54/74LS74 with an $\mathrm{f}_{\text {MAX }}$ of 25 MHz , all of the devices are guaranteed to operate at all clock frequencies, up to and including 25 MHz . Although no devices are guaranteed to operate above $f_{\text {MAX }}$ (only below it), most devices will operate beyond the maximum specification. The minimum limit does not state that the device will not operate below $f_{\text {MAX }}$ or that any devices that do are bad, but rather that all the devices will operate up to the limit.
Table IV shows the direction of the tighter testing for the more common AC parameters. All prop dealys (those AC parameters that have the symbols $t_{\text {PLH }}$ or $t_{\text {PHL }}$ ) have simple $\mathrm{min} / \mathrm{max}$ limits. The device is guaranteed to operate within the bounds of the $\mathrm{min} / \mathrm{max}$ limits, and any operation outside these limits denotes a device failure. $\mathrm{t}_{\text {SET-UP, }} \mathrm{t}_{\text {HOLD }} \mathrm{f}_{\text {MAX }}$, and treLEASE parameters have limits that denote guaranteed operation boundaries (i.e., the device is guaranteed to operate up to the boundary) but no guarantee is made concerning the device operation (or lack of it) beyond the boundary.
For detailed information on the AC waveforms, please see the test waveforms in this section.

TABLE IV. Looser/Tighter AC Test Limits Example: DM74ALS74A

| Test | From | Looser | Nominal | Tighter | Units |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{f}_{\max (\text { min }}$ |  | 33 | 34 | 35 | MHz |
| $t_{\text {PLH (max) }}$ | CLK | 17 | 16 | 15 | ns |
|  | PRE, CLR | 14 | 13 | 12 | ns |

## Designing with TTL

## National Semiconductor

 Application Note 363 Walt Sirovy54/74 series TTL has been used for more than a decade with excellent results, and continues to be a standard choice for design engineers because of the wide performance range and system optimization possible from the different families available. 54/74 logic comes in 8 different speed/power families (standard TTL, LS, S, ALS, AS, L, and F) that allow a design engineer to select device performance to suit his needs. Understanding the differences and the general limitations of all these families will go a long way toward insuring that a system will operate as intended with the minimum of corrections and redesigning.

## FAMILY COMPATIBILITY: Intermixing Logic Types in One Design

Family interchangeability is a beneficial characteristic of the different TTL families and provides the designer with the ability to customize specific areas of his design in order to accomplish the task of achieving both high performance and the lowest power consumption possible. However, interchangeability is not simply a matter of replacing, say, an SOO for an LSOO to improve the speed and replacing an LS00 for an S00 for power savings. One must also look at the DC and AC characteristics to insure that the replacement device will be compatible with the existing circuit. The DC problems include input loading and compatible output drive capabilities. The AC problems include insuring that the new device speeds will be acceptable to the rest of the system. The different logic families also generate different amounts of noise and have different noise immunity. Finally, measure points for the AC parameters of the different families, although very similar, do vary some, and this will require attention.

## SUPPLY RAILS: Why Not to Exceed the Specs

All bipolar logic (both junction and oxide isolated) is made up of selectively located regions of differently doped materials that form transistors, resistors, and diodes. Because of this, certain overall requirements are necessary to insure that the IC will be able to perform its task without interference from its environment. The first characteristic of bipolar devices is that the two power rails ( $V_{C C}$ and ground) represent the two voltage extremes that should be used in any system. Certain exceptions exist, primarily inputs and opencollector outputs that are pulled up to higher voltages than $\mathrm{V}_{\mathrm{CC}}$. However, while it is occasionally permissible to exceed the $\mathrm{V}_{\mathrm{CC}}$ specification, it is never permissible to drive any input or output more than 0.5 V below the ground reference. This limitation is due to the method used to electrically isolate the many circuit elements that are present on a bipolar IC. Oxide isolated devices use an oxide layer surrounding the various transistor and resistor tanks to provide an insulating barrier, while the original junction isolated devices use reverse biased PN junctions to provide that barrier. In both cases, the circuit is built on a P-type substrate that uses reverse biased PN junctions to separate the different circuit elements. The ground pin is electrically connected to the substrate and must be the most negative voltage on the device. When an input or output pin is taken below ground, the normally reverse biased isolation regions between the elements become forward biased and electrically connect
these elements together, thus eliminating the integrity of the circuit. This may or may not result in actual damage to the device depending upon the magnitude of the violating signal and the specifics of the device being violated. This holds true for both junction and oxide isolated logic. Oxide isolated logic may provide more margin before failing (thereby "working" in some marginal designs), but it is nevertheless subject to the same kind of limitations as junction isolated logic.

## IMPROPER GROUNDING: Noise Immunity, Floating Grounds

Bipolar logic uses the ground rail as the signal reference. Consequently, any modulation on the ground line will be directly added to the signal voltage. The logic " 0 " input noise margin is guaranteed as the difference between the $V_{O L}$ and $V_{\text {IL }}$ specification, and the logical " 1 " input noise margin is guaranteed as the difference between the $\mathrm{V}_{\mathrm{OH}}$ and $V_{I H}$ specification. This noise margin is intended to be protection against a reasonable amount of noise present. insufficient grounding techniques can cause significant $I_{R}$ and $I_{L}$ drops on the ground line between two ICs and result in a "floating" ground line. This is due to the large currents that are present on ground and $\mathrm{V}_{\mathrm{CC}}$ during high speed switching and means that the two devices are not using the same reference point. Any voltage drop in the ground line is added to the signal and ends up consuming some of the noise margin. Eventually, the mismatch caused by the floating ground will exceed the total noise margin and cause erroneous data to propagate through the system. The solutions to this problem are many and varied, but all of them revolve around improving the system grounding and include such ideas as providing separate signal and power grounds.

## $V_{C C}$ NOISE AND DECOUPLING: Providing Clean Power

The $V_{C C}$ power rail is also susceptible to both $I_{R}$ and $I_{L}$ voltage drops. The problems that arise from the $V_{C C}$ line are not the same as the problems that arise from the ground line. Since the $V_{O H}$ level tracks the $V_{C C}$ almost exactly, any voltage loss on the $\mathrm{V}_{\mathrm{CC}}$ line is directly transferred to the $\mathrm{V}_{\mathrm{OH}}$ level. However, the noise margin for the logic high state is typically 700 mV for commercial and 500 mV for military product, versus 400 mV and 300 mV for commercial and military product, respectively, for the logic low level. The main consequences of a drooping $V_{C C}$ line now become $\mathrm{I}_{\mathrm{OL}} / \mathrm{I}_{\mathrm{OH}}$ drive capability, and the AC performance in critical applications. Although bipolar devices are only guaranteed to operate over a given $\mathrm{V}_{\mathrm{CC}}$ range ( $5 \mathrm{~V} \pm 10 \%$ ), these devices typically function to $\mathrm{V}_{\mathrm{CC}}$ values as low as 4 V . Be aware that if the device does indeed function down to 4 V , the $A C$ and $D C$ characteristics will be compromised, some quite severely.
Designing in a good power distribution system will insure that all the devices in the circuit will perform the same, regardless of their physical location. Properly decoupling the $\mathrm{V}_{\mathrm{CC}}$ against both high and low frequency noise will help eliminate any problems with individual device operation. High frequency noise ( 100 MHz and above) comes primarily from two sources, while low frequency noise (less than 25 MHz ) results from primarily one source.

## SOURCES OF HIGH FREQUENCY NOISE ON THE VCC LINE

1) High frequency noise results from the device rapidly switching logic levels. The bulk of the switching current from a low to high transitions shows up in Icc current surges, while the bulk of the switching current from a high to low transition shows up in ground current surges.
2) Noise is transmitted through the changing magnetic fields that result from the changing electric fields in a switching line and are picked up on adjacent signal paths.
Note that the frequency causing the noise is not the signal's frequency, but the frequency of the signal's slew rate. For instance, in an SOO that is switching $O V$ to 3 V at 1 MHz , the slew rate of the output is typically about $1 \mathrm{~ns} / \mathrm{V}$, which is a frequency of around 160 MHz . The faster the slew rate, the higher the frequency, until one has an ideal square wave with infinite frequency. It is this frequency component that gives rise to the strong magnetic fields associated with switching bipolar devices.

## SOURCES OF LOW FREQUENCY NOISE ON THE VCC LINE

1) Low frequency noise results from the change in the I ICC current demand as devices change state. For instance, gates, flip-flops, and registers will draw different ICC currents, depending upon the state of the outputs.
The most commonly used method for countering these noise problems is to decouple the $V_{C C}$ line. With this approach, capacitors are used to stabilize the $V_{C C}$ line and filter out the unwanted frequency components. A small value capacitor (i.e., $0.1 \mu \mathrm{~F}$ ) is used near the device to insure that the transient currents arising from device switching and magnetic coupling are minimized. A large value capacitor (i.e., $50 \mu \mathrm{~F}$ to $100 \mu \mathrm{~F}$ ) is used on the board in general to accommodate the continually changing I CC requirements of the total $\mathrm{V}_{\mathrm{CC}}$ bus line. The following table shows a rough "rule of thumb" approach to determining how many capacitors to use for a given number if ICs. Be aware that the table is not a hard and fast rule, and that you must always evaluate your particular application to insure that there is sufficient $\mathrm{V}_{\mathrm{CC}}$ decoupling. When using these guidelines, be sure that the devices are located near each other and near the capacitor. If the capacitor is too far away, $I_{R}$ and $I_{L}$ drops will diminish the capacitor's effect. All capacitors (especially the $0.01 \mu \mathrm{Fs}$ ) must be high frequency RF capacitors. Disk ceramics are acceptable for this application. Keep in mind that, in synchronous systems, since a majority of the devices will be switching at once, alter your power distribution system accordingly.

## Device Family

AS, S, ALS, LS, H
TTL, L

## Number of Capacitors <br> 1 Cap per 1 device <br> 1 Cap per 2 devices

## TYING ALL UNUSED INPUTS TO A SOLID LOGIC LEVEL

Unused inputs on TTL devices float at threshold, anywhere from 1.1 V to 1.5 V , depending upon the device and its family. While this usually simulates a "high", many application problems can be traced to open inputs. Inputs floating at threshold are very susceptible to induced noise (transmitted from other lines) and can easily switch the state of the device. A good design rule is to tie unused inputs to a solid logic level. Inputs are usually tied to $\mathrm{V}_{\mathrm{CC}}$ through a $1 \mathrm{k} \Omega$ to $5 \mathrm{k} \Omega$ resistor, since tying them to ground means supplying the $I_{I L}$ current instead of the $I_{I H}$ current. $I_{I L}$ is several orders of magnitude greater than $\mathrm{I}_{\mathrm{IH}}$. The resistor is recommended
to protect the input against $V_{C C}$ voltage surges and to protect the system against the possibility of the input shorting directly to ground. A single 1 k resistor can handle up to 10 inputs.

## TERMINATIONS: Why Terminate a Transmission Line?

Whenever signals change voltage levels, a wavefront is created that propagates according to the characteristics of the transmission line being used. If the overall length of the signal path is short compared with the signal's wavelength ( 1 /frequency), then none of the complications of transmission lines are present. However, if the length of the signal path is long in comparison, then the wavefront will be significantly affected by the geometry and composition of that transmission line.
Fortunately, when dealing with a single board layout, the distances are usually short enough that one need not worry about the difficulties of terminating or impedance matching the line. However, if one is driving between boards or over long distances, he must be aware of the characteristics involved. When dealing with transmission lines it is necessary to know the impedance of the line. Every time the signal wavefront encounters a discontinuity (a point where the impedance changes, whether from a branch, junction or because of a change of environment), the opportunity for reflections and standing waves is present. These waves can easily cause the loss of the signal's integrity, having the ability to build voltages that are large enough to destroy an IC. Proper line termination will insure that the signal propagates down the line and is totally absorbed at the receiving end, thus preventing these waves from occurring.
Listed below is a guideline to the types of transmission lines to use when sending signals over various distances.
$0^{\prime \prime}$ to $12^{\prime \prime}$ Single wire conductor OK. Use point-to-point routing and avoid parallel routing if possible. Ground plane recommended, but not mandatory. Space conductors as far apart as possible to reduce line to line capacitance.
$12^{\prime \prime}$ to $6^{\prime}$ Dense ground plane required with wire routed as closely as possible. Twisted-pair lines or coaxial cable mandatory for clock lines and recommended for all sensitive control lines.
Over 6' Use fully terminated transmission lines. Avoid the use of radially distributed lines and avoid sharp bends in the line. Be aware that transmission lines have complex impedances and are not simply resistive in nature.

## BUS DRIVERS: On Board vs Off Board

Many of the TRI-STATE ${ }^{\circledR}$ buffers and flip-flops are intended to connect directly to the system bus and must be able to drive heavily capacitive loads. Keeping this in mind, all of National's LS TRI-STATE devices have "triple-sink" capability; that is, the $\mathrm{I}_{\mathrm{OL}}$ and $\mathrm{I}_{\mathrm{OH}}$ drive currents have been tripled. However, these devices are intended to drive single board buses. Driving off the board with these devices can easily lead to serious problems.
When using standard logic bus drivers on a single board, be aware that many of the octal and bus oriented devices have PNP inputs to reduce DC loading. PNP inputs on $54 \mathrm{~S} / 74 \mathrm{~S}$ devices tend to be more capacitive than the corresponding diode or emitter inputs, and as such, compromise the AC loading of the bus. Careful attention must be given to both DC and AC loading when driving heavily loaded buses. PNP
inputs on LS/AS/ALS operate at significantly lower currents and do not significantly increase capacitive load.
It is strongly recommended that any time a bus line leaves a board, interface bus drivers be used. These devices (see National's 1986 Interface/Databook) are specifically designed to impedance match different kinds of transmission lines and have the necessary current drive to handle the job. Using an ordinary logic device will usually yield poor results. If one must drive a transmission line with a logic device, there are some guidelines that should be followed to minimize the problems that can result.

1) Take care to properly terminate the bus. Be aware that every time a signal passes through a different impedance, an interface is created and that any impedance mismatch will result in reflections.
2) Never drive off the board with a bistable element like a flip-flop or a latch. This is because those devices are very susceptible to reflected waves changing their state. By buffering the output of the latch with another device, the reflected wave can affect the output of the buffer, but not the latch. This means that when the wave finally dies out, the latch will still have the proper data and the buffer will "snap back" to the proper output.
3) Be sure to carry an adequate ground plan with the signals and to shield the bus. Carrying a good ground plan (use multiple ground lines spaced around the connector if possible) will reduce the problem of floating ground, and the shielding will help protect the signal lines for induced noise. Using twisted-pair transmission lines for critical signals helps to eliminate the capacitive coupling that can degrade signals, or even cause false signals.
4) It is best to buffer any clock or control lines that depend upon fast, clean switching. Buffering at both the sending and receiving end will go a long way toward insuring that the clock can accomplish its goals.
5) Use the devices with Schmitt inputs to add to the noise margin of the receiving device. This will help increase the noise rejection of the system. Decouple each receiver separately, connecting the capacitor directly between ground and $\mathrm{V}_{\mathrm{CC}}$. Make sure that the device ground is tied directly to the bus ground.
6) If using open-collector devices to drive the bus, add a pull-up resistor on the input to the receiving device if the loL current of the driving device can handle it. A resistance in the $300 \Omega$ range will significantly improve the signal's rise time.

## AC LOADING: What Do AC Loads Look Like, and Why?

The standard AC load for all of the logic families, except ALS and AS, is built around a diode chain to ground and a pull-up resistor to $V_{C C}$ with added capacitance. This load is designed to look like the standard logic circuit input structure, and to simulate the appearance of switching in an actual application. For ALS and AS, the load is built around a resistor to ground and added capacitance. This is primarily for the requirements of high speed device testing. There also exists a set of standardized military AC loads that were
designed to approximate the input structure, while using no switches for the TRI-STATE parameters. Please see waveforms in this section. In the final analysis of these loads, it must be kept in mind that they represent a standard that can be used to determine the quality of an IC. No load will be able to predict exactly how a cievice will perform in a circuit or the speeds that a device can achieve in a good test jig with the spec load, as compared to the speeds that a device will produce in an application.

## OPEN-COLLECTOR DEVICES: What They Are, How to Use Them

Open-collector devices are totem pole outputs where the upper output (usually a Darlington transistor) is left out of the circuit. As such, these devices have no active logic high drive and cannot be used to drive a line high. The advantage to open-collector devices is that a number of outputs can be directly tied together. If one were to tie two complete totem pole outputs together, then at some time one output would be driving high while the other output was driving low. The result is that one device will be dumping excessive current directly into the other device. The resulting power dissipation in both devices can easily degrade the lifetime of the device. Since open-collector devices only have active drive in one state, if two connected devices drive to opposite states, the low state will always predominate and there will be no degradation to either device. Open-collector specifications are obvious by the lack of a $\mathrm{V}_{\mathrm{OH}}$ specification. The only $\mathrm{VOH}_{\mathrm{OH}} / \mathrm{l}_{\mathrm{OH}}$ specification is the leakage limits, and these are specified at $\mathrm{V}_{\mathrm{OH}}=5.5 \mathrm{~V}$.
When dealing with open-collector devices, it must be noted that each output requires a resistive pull-up, usually tied to $V_{C C}$. (By using high voltage outputs, one can tie the resistor pull-up to a voltage higher than $\mathrm{V}_{\mathrm{C}}$.) Designers often try to get away with tying the output to an input and relying on the $I_{I L}$ current to pull up the output. This is unwise, as it is just like leaving inputs floating: the input is very susceptible to noise and can easily give false signals. Shown below are two equations that can be used to determine the $\mathrm{min} / \mathrm{max}$ range of the pull-up resistor.

$$
\begin{aligned}
& R_{M A X}=\frac{\left(V_{C C(M I N)}-V_{O H}\right)}{\left(N 1 \cdot I_{O H}+N_{2} \cdot I_{I H}\right)} \\
& R_{M I N}=\frac{\left(V_{C C(M I N)}-V_{O L}\right)}{\left(I_{\mathrm{OL}}-N_{2} \cdot I_{I L}\right)}
\end{aligned}
$$

where: $\mathrm{N} 1=$ the number of open-collector devices tied together,
$\mathrm{N} 2=$ the number of inputs being driven on the line. If the maximum resistance is exceeded, then it is possible for the total leakage currents from all of the inputs and outputs to pull the $\mathrm{V}_{\mathrm{OH}}$ level below the spec value. Likewise, if the $\mathrm{R}_{\text {MIN }}$ value is exceeded, then the driving device may not be able to pull down the signal line to a solid $\mathrm{V}_{\mathrm{OL}}$. Either of these two cases can easily result in false logic levels being propagated through the system.

# Designer's Encyclopedia of Bipolar One-Shots 

## INTRODUCTION

National Semiconductor manufacturers a broad variety of industrial bipolar monostable multivibrators (one-shots) in TTL and LS-TTL technologies to meet the stringent needs of systems designers for applications in the areas of pulse generation, pulse shaping, time delay, demodulation, and edge detection of waveforms. Features of the various device types include single and dual monostable parts, retriggerable and non-retriggerable devices, direct clearing input, and DC or pulse-triggered inputs. Furthermore, to provide the designer with complete flexibility in controlling the pulse width, some devices also have Schmitt trigger input, and/or contain internal timing components for added design convenience.

## DESCRIPTION

One-shots are versatile devices in digital circuit design. They are actually quite easy to use and are best suited for applications to generate or to modify short timings ranging from several tens of nanoseconds to a few microseconds. However, difficulties are constantly being experienced by design and test engineers, and basically fall into the categories of either pulse width problems or triggering difficulties.
The purpose of this note is to present an overall view of what one-shots are, how they work, and how to use them properly. It is intended to give the reader comprehensive information which will serve as a designer's guide to bipolar one-shots.
Nearly all malfunctions and failures on one-shots are caused by misuse or misunderstanding of their fundamental operating rules, characteristic design equations, param-

National Semiconductor
Application Note 372
Kern Wong

eters, or more frequently by poor circuit layout, improper bypassing, and improper triggering signal.
In the following sections all bipolar one-shots manufactured by National Semiconductor are presented with features tables and design charts for comparisons. Operating rules are outlined for devices in general and for specific device types. Notes on unique differences per device and on special operating considerations are detailed. Finally, truth tables and connection diagrams are included for reference.

## DEFINITION

A one-shot integrated circuit is a device that, when triggered, produces an output pulse width that is independent of the input pulse width, and can be programmed by an external Resistor-Capacitor network. The output pulse width will be a function of the RC time constant. There are various one-shots manufactured by National Semiconductor that have diverse features, although, all one-shots have the basic property of producing a programmable output pulse width. All National one-shots have True and Complementary outputs, and both positive and negative edge-triggered inputs.

## OPERATING RULES

In all cases, R and C represented by the timing equations are the external resistor and capacitor, called REXT and $\mathrm{C}_{\mathrm{EXT}}$, respectively, in the data book. All the foregoing timing equations use $C$ in $p F, R$ in $K \Omega$, and yield $t_{W}$ in nanoseconds. For those one-shots that are not retriggerable, there is a duty cycle specification associated with them that

[^0]defines the maximum trigger frequency as a function of the external resistor, REXT.
In all cases, an external (or internal) timing resistor ( $\mathrm{R}_{\mathrm{EXT}}$ ) connects from $\mathrm{V}_{\mathrm{CC}}$ or another voltage source to the " $\mathrm{R}_{\mathrm{EXT}}$ / $\mathrm{C}_{\text {EXT' }}$ pin, and an external timing capacitor ( $\mathrm{C}_{E X T}$ ) connects between the " $\mathrm{R}_{\text {EXT }} / \mathrm{C}_{E X T}$ ", and " $\mathrm{C}_{\text {EXT }}$ " pins are required for proper operation. There are no other elements needed to program the output pulse width, though the value of the timing capacitor may vary from 0.0 to any necessary value.
When connecting the $\mathrm{R}_{\text {EXT }}$ and $\mathrm{C}_{\text {EXT }}$ timing elements, care must be taken to put these components absolutely as close to the device pins as possible, electrically and physically. Any distance between the timing components and the device will cause time-out errors in the resulting pulse width, because the series impedance (both resistive and inductive) will result in a voltage difference between the capacitor and the one-shot. Since the one-shot is designed to discharge the capacitor to a specific fixed voltage, the series voltage will "fool" the one-shot into releasing the capacitor before the capacitor is fully discharged. This will result in a pulse width that appears much shorter than the programmed value. We have encountered users who have been frustrated by pulse width problems and had difficulty to perform correlations with commercial test equipment. The nature of such problems are usually related to the improper layout of the DUT adapter boards. (See Figure 6 for a PC layout of an AC test adapter board.) It has been demonstrated that lead length greater than 3 cm from the timing component to the device pins can cause pulse width problems on some devices.
For precise timing, precision resistors with good temperature coefficient should be used. Similarly, the timing capacitor must have low leakage, good dielectric absorption characteristics, and a low temperature coefficient for stability. Please consult manufacturers to obtain the proper type of component for the application.
For small time constants, high-grade mica glass, polystyrene, polypropylene, or polycarbonate capacitor may be used. For large time constants, use a solid tantalum or special aluminum capacitor.
In general, if a small timing capacitor is used that has leakage approaching 100 nA or if the stray capacitance from either terminal to ground is greater than 50 pF , then the timing equations or design curves which predict the pulse width would not represent the programmed pulse width which the device generates.
When an electrolytic capacitor is used for $\mathrm{C}_{\text {EXT }}$, a switching diode is often suggested for standard TTL one-shots to prevent high inverse leakage current (Figure 1). In general, this switching diode is not required for LS-TTL devices; it is also not recommended with retriggerable applications.

TL/F/7508-1
FIGURE 1

It is never a good practice to leave any unused inputs of a logic integrated circuit "floating". This is particularly true for one-shots. Floating uncommitted inputs or attempts to establish a logic HIGH level in this manner will result in malfunction of some devices.
Operating one-shots with values of the $R_{E X T}$ outside the recommended limits is at the risk of the user. For some devices it will lead to complete inoperation, while for other devices it may result in either output pulse widths different from those values predicted by design charts or equations, or with modes of operation and performance quite different from known standard characterizations.
To obtain variable pulse width by remote trimmiing, the following circuit is recommended (Figure 2). "RREMOTE" should be placed as close to the one-shot as possible.

FIGURE 2
$\mathrm{V}_{\mathrm{CC}}$ and ground wiring should conform to good high frequency standards and practices so that switching transients on the $V_{C C}$ and ground return leads do not cause interaction between one-shots. A $0.001 \mu \mathrm{~F}$ to $0.1 \mu \mathrm{~F}$ bypass capacitor (disk or monolithic type) from the $V_{C C}$ pin to ground is necessary on each device. Furthermore, the bypass capacitor shoud be located so as to provide as short an electrical path as possible between the $V_{C C}$ and ground pins. In severe cases of supply-line noise, decoupling in the form of a local power supply voltage regulator is necessary.
For retriggerable devices the retrigger pulse width is calculated as follows for positive-edge triggering:

FIGURE 3

$$
t_{R E T}=t_{W}+t_{P L H}=K \cdot\left(R_{E X T}\right)\left(C_{E X T}\right)+t_{P H L}
$$

(See tables for exact expressions for $K$ and $t_{w} ; K$ is unity on most HCMOS devices.)

## SPECIAL CONSIDERATIONS AND NOTES:

The 9601 is the single version of the dual 9602 one-shot. With the exception of an internal timing resistor, $\mathrm{R}_{\mathrm{INT}}$, the 'LS122 has performance characteristics virtually identical to the 'LS123. The design and characteristic curves for equivalent devices are not depicted individually, as they can be referenced from their parent device.
National's TTL-'123 dual retriggerable one-shot features a unique logic realization not implemented by other manufacturers. The "CLEAR" input does not trigger the device, a design tailored for applications where it is desired only to terminate or to reduce the timing pulse width.

The 'LS221, even though it has pin-outs identical to the 'LS123, is not functionally identical. It should be remembered that the 'LS221 is a non-retriggerable one-shot, while the 'LS123 is a retriggerable one. For the 'LS123 device, it is sometimes recommended to externally ground its " $\mathrm{C}_{\text {EXT }}$ " pin for improved system performance. The "C $\mathrm{C}_{E T}$ " pin on the 'LS221, however, is not an internal connection to the device ground. Hence, grounding this pin on the 'LS221 device will render the device inoperative.
Furthermore, if a polarized timing capacitor is used on the 'LS221, the positive side of the capacitor should be connected to the "CEXT" pin. For the 'LS123 part, it is the contrary, the negative terminal of the capacitor should be connected to the " CEXT " pin of the device (Figure 4).

FIGURE 6a. AC Test Adapter

The 'LS221 trigger on "CLEAR": This mode of trigger requires first the "B-Input" be set from a Low-to-High level while the "CLEAR" input is maintained at logic Low level. Then, with the "B" Input at logic High level, the "CLEAR" input, whose positive transition from LOW-to-HIGH will trigger an output pulse (" $A$ input" is LOW).

FIGURE 5

## AC Test Adapter Board

The compact PC layout below is a universal one-shot test adapter board. By wiring different jumpers, it can be configured to accept all one-shots made by National Semiconductor. The configuration shown below is dedicated for the '123 device. It has been used successfully for functional and pulse width testing on all the ' 123 families of one-shots on the MCT AC test system.

## Typical Output Pulse Width vs Timing Components

Timing equations listed in the features tables hold all combinations of $\mathrm{R}_{\text {EXT }}$ and $C_{E X T}$ for all cases of $\mathrm{C}_{\text {EXT }}>$ 1000 pF . For cases where the $\mathrm{C}_{\text {EXT }}<$ 1000 pF , use graphs shown below.

TL/F/7508-9

## Typical Output Pulse Width Variation vs Ambient Temperature

The graphs shown below demonstrate the typical shift in the device output pulse widths as a function of temperature. It should be noted that these graphs represent the temperature shift of the device after being corrected for any temperature shift in the timing components. Any shift in these components will result in a corresponding shift in the pulse width, as well as any shift due to the device itself.

74LS221

DM74LS123

TL/F/7508-10

## Typical Output Pulse Width Variation vs Supply Voltage

The following graphs show the dependence of the pulse width on $V_{\mathrm{CC}}$.
As with any IC applications, the device should be properly bypassed so that large transient switching currents can be easily supplied by the bypass capacitor. Capacitor values of $0.001 \mu \mathrm{~F}$ to $0.10 \mu \mathrm{~F}$ are generally used for the $V_{C C}$ bypass capacitor.

## Typical "K" Coefficient Variation vs Timing Capacitance

For certain one-shots, the " K " coefficient is not a constant, but varies as a function of the timing capacitor $\mathrm{C}_{\mathrm{EXT}}$ The graphs below detail this characteristic.

DM74LS221

TL/F/7508-12

## Typical Output Pulse Width vs Minimum Timing Resistance

The plots shown below demonstrate typical pulse widths and limiting values of the true output as a function of the external timing resistor, $\mathrm{R}_{\text {EXT }}$. This information should evaporate those years of mysterious notions and numerous concerns about operating one-shots with lower that recommended minimum $\mathrm{R}_{\text {EXT }}$ values.

## Applications

The following circuits are shown with generalized one-shot connection diagram.

## NOISE DISCRIMINATOR (Figure 8)

The time constant of the one-shot (O-S) can be adjusted so that an input pulse width narrower than that determined by the time constant will be rejected by the circuit. Output at $Q_{2}$

## Connection Diagrams (Continued)

54LS221 (J, W); 74L.S221 (N)

will follow the desired input pulse, with the leading edge delayed by the predetermined time constant. The output pulse width is also reduced by the amount of the time constant from $\mathrm{R}_{\mathrm{X}}$ and $\mathrm{C}_{\mathrm{X}}$.

FIGURE 8. Noise Discriminator

TL/F/7508-23
FIGURE 8. Noise Discriminator (Continued)

## FREQUENCY DISCRIMINATOR (Figure 9)

The circuit shown in Figure 9 can be used as a frequency-to-voltage converter. For a pulse train of varying frequency applied to the input, the one-shot will produce a pulse con-

stant width for each triggering transition on its input. The output pulse train is integrated by $R_{1}$ and $C_{1}$ to yield a waveform whose amplitude is proportional to the input frequency. (Retriggerable device required.)

TL/F/7508-25

TL/F/7508-24
FIGURE 9. Frequency Discriminator

## ENVELOPE DETECTOR (Figures 10a and 10b)

An envelope detector can be made by using the one-shot's retrigger mode. The time constant of the device is selected to be slightly longer than the period of each cycle within the input pulse burst. Two distinct DC levels are present at the output for the duration of the input pulse burst and for its

TL/F/7508-26

absence (see Figure 10a). The same circuit can also be employed for a specific frequency input as a Schmitt trigger to obviate input trigger problems associated with hysteresis and slow varying, noisy waveforms (see Figure 10b). (Retriggerable device required.)

TL/F/7508-27
FIGURE 10b. Schmitt Trigger

Two one-shots can be connected together to form a pulse generator capable of variable frequency and independent duty cycle control. The $\mathrm{R}_{\mathrm{X} 1}$ and $\mathrm{C}_{\mathrm{X} 1}$ of $\mathrm{O}-\mathrm{S} 1$ determine
the frequency developed at output $Q_{1}$. RX2 and $C_{X 2}$ of $\mathrm{O}-\mathrm{S} 2$ determine the output pulse width at $\mathrm{Q}_{2}$. (Retriggerable device required.)

FIGURE 11. Pulse Generator (Retriggerable Device Required)
Note: K is the multiplication factor dependent of the device. Arrow indicates edge-trigger mode.

## DELAYED PULSE GENERATOR WITH OVERRIDE TO

 TERMINATE OUTPUT PULSE (Figure 12)An input pulse of a particular width can be delayed with the circuit shown in Figure 12. Preselected values of $\mathrm{R}_{\mathrm{X} 1}$ and $\mathrm{C}_{\mathrm{X} 1}$ determine the delay time via $\mathrm{O}-\mathrm{S} 1$, while preselected
values of $\mathrm{R}_{\mathrm{X} 2}$ and $\mathrm{C}_{\mathrm{X} 2}$ determine the output pulse width through O-S2. The override input can additionally serve to modify the output pulse width.

FIGURE 12. Delayed Pulse Generator with Override to Terminate Output Pulse

MISSING PULSE DETECTOR (FIgure 13)
By setting the time constant of $O-S 1$ through $\mathrm{R}_{\mathrm{X} 1}$ and $\mathrm{C}_{\mathrm{X}}$ to be the least one full period of the incoming pulse period, the one-shot will be continuously retriggered as long as no missing pulse occurs. Hence, $\bar{Q}_{1}$ remains LOW until a pulse
is missing in the incoming pulse train, which then triggers $\mathrm{O}-\mathrm{S} 2$ and produces an indicating pulse at $\mathrm{Q}_{2}$. (Retriggerable device required.)

PULSE WIDTH DETECTOR (Figure 14)
The circuit of Figure 14 produces an output pulse at $\mathrm{V}_{\text {OUT }}$ if the pulse width at $\mathrm{V}_{\text {IN }}$ is wider than the predetermined pulse width set by $\mathrm{R}_{\mathrm{X}}$ and $\mathrm{C}_{\mathrm{X}}$.

TL/F/7508-35
FIGURE 14. Pulse Width Detector

TL/F/7508-36
FIGURE 14. Pulse Width Detector (Continued)

BAND PASS FILTER (Figure 15)
The band pass of the circuit is determined by the time constants of the two low-pass filters represented by O-S1 and O -S2. With the output at $\mathrm{Q}_{2}$ delayed by C , the D -flip flop
(D-FF) clocks HIGH only when the cutoff frequency of O-S2 has been exceeded. The output at $Q_{3}$ is gated with the delayed input pulse train at $Q_{4}$ to produce the desired output. (Retriggerable device required.)

TL/F/7508-37

FIGURE 15. Band Pass Filter (Retriggerable Device Required)

## FM DATA SEPARATOR (Figure 16)

The data separator shown in Figure 16 is a two-time constant separator that can be used on tape and disc drive memory storage systems. The clock and data pulses must fall within prespecified time windows. Both the clock and data windows are generated in this circuit. There are two data windows; the short window is used when the previous bit cell had a data pulse in it, while the long window is used when the previous bit cell had no data pulse.
If the data pulse initially falls into the data window, the -SEP DATA output returns to the NAND gate that generates the data window, to assure that the full data is allowed through before the window times out. The clock windows will take up the remainder of the bit cell time.
Assume all one-shots and flip-flops are reset initially and the + READ DATA has the data stream as indicated.

With $\mathrm{O}-\mathrm{S} 1$ and $\mathrm{O}-\mathrm{S} 2$ inactive, + CLK WINDOW is active. The first + READ DATA pulse will be gated through the second AND gate, which becomes -SEP CLK for triggering of the R-S FF and the one-shots. With the D-FF off, O-S1 will remain reset. The -SEP CLK pulse will trigger O-S2, whose output is sent to the OR gate, and its output becomes + DATA WINDOW to enable the first AND gate. The next pulse on + READ DATA wil be allowed through the first AND gate to become -SEP DATA. This pulse sets the R-S FF, whose HIGH output becomes the data to the D-FF. The D-FF is clocked on by O-S2 timing out and +CLK WINDOW becoming active. $\bar{Q}_{4}$ will hold $\mathrm{O}-\mathrm{S} 2$ reset and allow O-S1 to trigger on the next clock pulse.

FIGURE 16. FM Data Separator

The next clock pulse (the second bit cell) is ANDed with + CLK WINDOW and becomes the next -SEP CLK, which will reset the R-S FF and trigger O-S1. As O-S1 becomes active, the + DATA WINDOW becomes active, enabling the first AND gate. With no data bit in the second bit cell, the R-S FF will remain reset, enabling the D-FF to be clocked off when +DATA WINDOW falls. When the D-FF is clocked off, $Q_{4}$ will hold $\mathrm{O}-\mathrm{S} 1$ reset and allow O-S2 to be triggered.
The third clock pulse (bit cell 3) is ANDed with + CLK WINDOW and becomes -SEP CLK, which continues re-
setting the R-S FF and triggers $\mathrm{O}-\mathrm{S} 2$. When $\mathrm{O}-\mathrm{S} 2$ becomes active, +DATA WINDOW enables the first AND gate, allowing the data pulse in bit cell 3 to become -SEP DATA. This -SEP DATA will set the R-S FF, which enables the D-FF to be clocked on when + DATA WINDOW falls. When this happens, $Q_{4}$ will hold $O-S 2$ reset and allow $\mathrm{O}-\mathrm{S} 1$ to trigger. This procedure continues as long as there is clock and data pulse stream present on the +READ DATA line.

TL/F/7508-40
FIGURE 16. FM Data Separator (Continued)

## PHASE-LOCKED LOOP VCO (Figure 17)

The circuit shown in Figure 17 represents the VCO in the data separation part of a rotational memory storage system which generates the bit rate synchronous clocks for write data timing and for establishing the read data windows.
The op-amp that performs the phase-lock control operates by having its inverting input be driven by two sources that normally buck one another. One source is the one-shot, the other source is the phase detector flip-flop. When set, the one-shot, through an inverter, supplies a HIGH-level voltage to the summing node of the op-amp and the phase detector FF, also through an inverter, supplies a canceling LOW-level input.
It is only when the two sources are out of phase with each other, that is one HIGH and the other LOW, that a positiveor negative-going phase error will be applied to the op-amp to effect a change in the VCO frequency. Figure 17 illustrates the process of phase-error detection and correction when synchronizing to a data bit pattern. The rising edge of each pulse at DATA+PLO clocks the one-shot LOW and the phase detector FF HIGH. Since both outputs are still bucking each other, no change will be observed at the
phase-error summing node. When the one-shot times out, if this occurs after the 2 F clock has reset the phase detector FF to a LOW output, a positive pulse will be seen at the summing node until both the one-shot and the FF are reset. Any positive pulse will be reflected by a negative change in the op-amp output, which is integrated and reduces the positive control voltage at the VCO input in direct proportion to the duration of the phase-error pulse. A negative phase-error pulse occurs when the phase detector FF remains set longer than the one-shot.
Negative phase-error pulse causes the integrated control voltage to swing positive in direct proportion to the duration of the phase-error pulse. It is recommended that a clamping circuit be connected to the output of the op-amp to prevent the VCO control voltage from going negative or more positive than necessary. A back-to-back diode pair connected between the op-amp and the VCO is highly recommended, for it will present a high impedance to the VCO input during locked mode. This way, stable and smooth operation of the PLO circuit is assured.

## A FINAL NOTE

It is hoped that this brief note will clarify many pertinent and subtle points on the use and testing of one-shots. We invite your comments to this application note and solicit your constructive criticism to help us improve our service to you.

## ACKNOWLEDGEMENT

The author wishes to thank Stephen Wong, Bill Llewellyn, Walt Sirovy, Dennis Worden, Stephen Yuen, Weber Lau, Chris Henry and Michelle Fong for their help and guidance.

## Guide to ALS and AS

## INTRODUCTION

Since the introduction of the first bipolar Transistor-Transistor Logic (TTL) family (DM54/74), system designers have wanted more speed, less power consumption, or a combination of the two attributes. These requirements have spawned other logic families such as the DM54/74L (low power), DM54/74LS (low power Schottky), DM54/74S (Schottky), etc., in order to give the system designers some choice.
The most common way of comparing logic families is by using their speed-power products. Figure 1 displays a graphical representation of the logic families now available. The addition of the Advanced logic families broadens the spectrum of speed/power characteristics. This will allow the system designer to optimize his system's speed/power product by using performance budgeting. Performance budgeting is the intermixing of logic families to achieve the best speed/power product for a design. This is possible since bipolar logic families are designed to be fully compatible with each other. When the designer uses performance budgeting he is trading power consumption for speed. The designer identifies the speed critical paths and uses the fastest products to optimize the system's speed. For all other non-critical speed paths, the logic family with the best speed/power product should be used to optimize his system's power consumption. Since no other family offers the speed capability of AS and the low power of ALS, these families are the best choice when performance budgeting.

TL/F/9158-1

## FIGURE 1. Speed Power Product Comparison

Each of the logic families is a compromise between speed and power consumption. Since the speed/power product is approximately a constant, a decrease in the power consumption must be traded off in a slowing down of the device and vice versa. The power consumption of a device is the easiest to control. By simply increasing the resistive values in the circuit the power consumption can be decreased.
The device speed can be handled in a similar manner. The speed of a device is limited by the charge stored in the transistors of the circuits. The time to remove this charge is proportional to the capacitance of the transistor and the current supplied. In the early speed improvements, the current aspect of this relationship was involved. A simple decrease in the resistive values in the circuits was done. This did help the speed but it greatly increased the power consumption. The advent of the Schottky transistor helped increase the

National Semiconductor Application Note 476
Walt Sirovy

device speed. The Schottky transistor adds a Schottky clamp diode between the base and collector of the transistor. The Schottky clamp diode has a lower forward voltage (about 0.4 V ) than the base-collector junction diode (about 0.5 V ). When the transistor is turned on the base current drives the transistor toward saturation and the collector voltage drops. This causes the Schottky clamp diode to conduct and divert some of the base current from the base-collector junction of the transistor. This clamp diode prevents the transistor from going into deep saturation. This allows the transistor to recover quickly by decreasing the transistor storage time. The Schottky logic families (DM54/74S, DM54/74LS) used the Schottky transistor and low values of resistors to achieve their high speeds.
Now NSC has introduced the Advanced Low Power Schottky (ALS) and the Advanced Schottky (AS) logic families. These families use a reduced transistor size, advanced process technology, and innovative design techniques to achieve the improved device speeds. This article will discuss various aspects of the Advanced logic families including design goals, application goals, circuit design enhancements, family features, and some helpful application tips.

## ADVANCED LOGIC FAMILIES DESIGN GOALS

For the Advanced logic families our main design goal was to reduce the power consumption while improving the speed of the parts. We also set the requirement that the Advanced logic parts be pin for pin compatible with existing logic families to allow ease of system upgrading and interfacing with existing products.
The design goals for ALS family were to produce a complete logic family which would achieve one half the propagation delays of DM54/74LS at one half the power dissipation of DM54/74LS and improve the capability of the outputs to drive 50 to $100 \Omega$ lines.
For the AS family the design goal was to produce a complete logic family which would achieve one half the propagation delays of DM54/74S at one third the power dissipation of DM54/74S.
We set some goals for both Advanced logic families that were more application related because of our experience with other logic families. These goals were to improve the input characteristics and line driving capability, reduce internally generated supply current spikes, eliminate parasitic failure modes and decoding glitches, and provide better electro-static discharge protection.

## AN OVERVIEW OF THE ADVANCED LOGIC FAMILIES

The Advanced logic families (ALS \& AS) have included most of the functions now present in the DM54/74LS and DM54/74S families. Some additions have been made to the Advanced families over the DM54/74LS and S families in order to make the families more complete. Both of the Advanced families have added a better (more complete) selection of octal bus transceivers, transparent latches and Dtype flip-flops. A series of logic gate drivers ( 800 series) have been added to the ALS family. These devices have increased logic high and low current capabilities which allow the driving of high capacitive lines. These drivers have also been added to the AS family but have been designated the 1000 series. The ALS family has also added a series of gate
buffers ( 1000 series) which increase the fanout of these devices by increasing the logic low and high driving capabilities (but not as much as the 800 series).
The datasheets for the Advanced Logic devices have been improved in order to more accurately reflect application requirements and to reduce the need for special testing. The supply voltage range for the commercial products has been defined as $10 \%$ ( 4.5 V to 5.5 V ) instead of $5 \%$ as all other bipolar logic have done in the past. The high level output voltage specification has been changed to $\mathrm{V}_{\mathrm{CC}}-2$ to allow easier interfacing with CMOS parts which have $V_{C C}$ sensitive thresholds and to better reflect the actual operation of the parts. The output drive current ( $I_{0}$ ) is measured at a forcing voltage of 2.25 V instead of OV used by other logic families. This demonstrates that the Advanced logic families have sourcing capability through the threshold level of the next gate. The low level input current ( $l_{\mathrm{L}}$ ) specification has been reduced from - $400 \mu \mathrm{~A}$ used for DM54/74LS to - 100 $\mu \mathrm{A}$ for ALS. This indicates that ALS devices' ILL current is less of a dominant factor in the limiting of device fanout. Current sinking capability (IOL) for the AS family of TRI-STATE devices has been substantially increased (20 to 48 mA ) over the DM54/74S family to allow the connection of these parts to a heavily loaded bus. The dynamic characteristics (propagation delays, etc.) have been specified over the supply voltage and temperature range. Also the output load used to test the dynamic characteristics has been simplified to allow easier construction of hardware for automatic test equipment and still reflect in-circuit operation. These items should give the designer a higher confidence level of the product used in his systems. Table 1 shows a comparison between ALS/AS and LS/S product. Appendix A includes generic datasheets for ALS and AS family of products.

## CIRCUIT DESIGN ENHANCEMENTS

One of the design enhancements of the Advanced logic families is the improvement of the input threshold voltage. Figures 4 (ALS schematic) and 5 (AS schematic) are used for reference for the following discussion. The input threshold is determined by the following equation.

$$
V_{\text {threshold }}=V_{\mathrm{BE}(\mathrm{Q} 2)}+V_{\mathrm{BE}(\mathrm{Q} 3)}+V_{\mathrm{BE}(\mathrm{Q4)}}-\mathrm{V}_{\mathrm{BE}(\mathrm{Q} 1)}
$$

The typical VBE of these transistors is 0.7 V . Therefore the typical threshold voltage is 1.4 V . This optimizes the threshold point between the high and low level input voltages. This provides maximum noise immunity. Figure 2 demonstrates the threshold enhancement.

Another of the design enhancements is the use of a PNP transistor in the input circuitry. The use of the PNP transistor reduces the typical $I_{L L}$ of these circuits ( $-10 \mu \mathrm{~A}$ for ALS and $-50 \mu \mathrm{~A}$ for AS). When using a PNP transistor the equation for IIL becomes:

$$
\begin{aligned}
& I_{I L}=\frac{V_{C C}-V_{B E(Q 1)}-V_{I}}{R\left(h_{F E(Q 1)}+1\right)} \\
& \text { (2) }
\end{aligned}
$$

TL/F/9158-2
FIGURE 2. $V_{\text {IN }}$ vs $V_{\text {OUT }}$
Past logic families which used diodes or NPN transistors at the inputs had higher I/L since they lacked the gain ( $h_{\text {FE }}$ ) of the PNP transistor. The PNP transistor of the Advanced families effectively eliminates the $I_{\text {IL }}$ current from being a dominant limiting factor in device fanout. The fanout constraints are now primarily associated with AC loading.
The input clamping and electrostatic discharge protection methods have also been improved. Past circuits have used diodes to do the negative voltage clamping action. The Advanced logic circuits use a Schottky transistor with the base and the emitter shorted to ground. The forward resistance of the base-collector is less than the diodes used in previous logic families. This lower resistance allows higher currents to be absorbed. This has improved the electrostatic discharge resistance from less than 1000 V to 4000 V . This gives the Advanced logic families a non-sensitive rating for the MIL-M-38510 people.
The lower output characteristic has been improved by the addition of the transistor (Q9) for the AS parts and the diode (D3) for the ALS. These elements provide additional base drive for the lower output transistor (Q5) when the output transitions from a high to low state. Thus the transistor pair Q3 and Q5 acts as a darlington pair. The AS parts use a transistor instead of the diode because of the higher drive requirements. Figure 3 shows the Advance families output

Vo - OUTPUT VOLTAGE(V)

FIGURE 3. Low Logic Level V OUT vs IOUT

TL/F/9158-5
FIGURE 4. ALS00 Schematic

FIGURE 5. ASOO Schematic
characteristic compared to the old Schottky families. Note that the current sink capability of the AS family takes off at 1.5V while the DM54/74S family remains flat. The ALS graph shows a similar characteristic but the break point is 1.8 V .

The Advanced logic families include the output shaping circuit used in most modern bipolar logic families. This circuit consisting of transistor Q4, resistor R7 and resistor R8 helps to turn off the low output transistor Q5 during the low to high output transition. The diode D7 is used to help turn off the upper output transistor (Q7).

The AS circuits incorporate additional circuitry to reduce current supply spikes. During a low to high transition a supply current spike can be produced because the lower output transistor (Q5) remains temporarily on. This can increase the power consumed by the circuit especially at high frequencies. The lower output transistor remains on because of charge being coupled by this transistor's base-collector capacitance. The circuitry used to eliminate this problem is the addition of a transistor (Q9), two diodes (D8 \& D11), and two resistors (R9 \& R10). This circuit has been named the Miller killer. The diode (D8) is used as a capacitor to couple charge into the base of the transistor, Q9, during a low to high transition of the output. Thus Q9 turns on providing a means of turning off the lower output transistor (Q5). This circuitry is not required for most ALS devices due to the lower frequency of operation and smaller output structures.

## APPLICATION RELATED DESIGN IMPROVEMENTS

A major consideration in the layout of the Advanced logic families was their response to negative transients. The Advanced logic families have high transition rates which can generate large reflections ( -2.5 volts) when terminated into a high impedance. A method of limiting reflections is to use a clamp diode. All the Advanced logic devices include Schottky clamp diodes on both the inputs and outputs. These clamp diodes may have to handle peak currents of 30 to 60 mA . At these currents substrate junctions will become forward biased.
Figure 6 shows a cross sectional view of the area of an Advanced logic device where a negative transient may be a problem. A negative transient on an input or output tank (the structure in the center) will forward bias the substrate to N epi junction. This will form a parasitic NPN transistor between adjacent structures. If the adjacent structure is an input or output the only impact will be an increase in the leakage current. Since most of the devices have an active totem pole output design a logic state change does not happen. If the adjacent structure is a collector of an internal transistor the increase in the leakage current may cause a logic state change from a high logic state to a low logic state. This state change in a combinational logic part can propagate to the output and cause a glitch which can affect the system performance. If the adjacent transistor is part of a flip-flop a change in the logic state can happen. This can cause a sequential error in the system.

TL/F/9158-6
FIGURE 6. Parasitic Failures Modes

Figure 7 demonstrates the method we use to minimize this problem. A grounded $\mathrm{N}+$ guard ring around all input and output transistors is included. The guard ring increases the spacing between the two structures thus reducing the efficiency of the parasitic transistor. The grounded guard ring also acts as an energy well which collects the majority of the electrons injected by the parasitic transistor. An example of the amount of protection achieved can be demonstrated by looking at the ALS74. Without the guard ring this device will change state with only -5 mA input current. With a guard ring the device can withstand in excess of -35 mA input current with no change in logic state and only a few tenths of a volt degradation of the high state logic level.
Another problem associated with older logic families is decoding glitches. The old method of decoding is demonstrated in Figure 8. A decoding glitch occurs when the A and B inputs are at a high logic level and the select input transitions from a low to high logic level. The propagation delay from a high to a low logic level is faster for the inverting gate than the propagation delay from a low to high logic level is for the non-inverting gate. This causes both the SEL and the SEL' lines to be at a low logic level for a short time. If both these lines are at a low logic level at the same time the Y output will transition to a low logic level even if the $A$ and $B$ inputs are at a high logic level. With the circuit used for the Advanced logic families (Figure 9) the SEL' line cannot go to a low logic level until the SEL line goes to a high logic level since the SELECT and SEL lines are logically connected with a NAND gate.

## PROCESS DESCRIPTION

A major factor which allowed us to meet our design goals is the Advanced Schottky process. The Advanced Schottky process uses oxide isolation and ion implantation. This allows the physical size of the transistors to be reduced.
Figure 10 shows the size comparison between a junction isolated and oxide isolated transistors. The oxide isolated transistor is more than half the size of the junction isolated transistor. This reduction in size provides higher packing density and, most important, smaller active junction areas ( $2.5 \mu$ emitter width). The oxide isolated structure has much smaller capacitance due to the reduced geometries thus improving the speed/power performance ( 5 GHz FT ).
Figure 11 shows a cross sectional view comparison between the junction and oxide isolation processes. In the oxide isolated process the emitter of the transistor contacts the oxide isolation directly (walled emitter). This greatly reduces the side wall capacitance since the capacitance is inversely proportional to the dielectric constant and dielectric constant between silicon/oxide is much smaller than the dielectric constant between two sections of silicon.
lon implantation is a technique of introducing impurities by bombarding the host material with a beam of ions. This technique is superior to the deposition method used in previous processes because it is easier to control the amount of impurities introduced into the silicon. The deposition method relies on control of diffusion time, diffusion temperature, gasflow rate and surface cleaniness. Ion implantation relies on the control of only current and voltage of the machine.
Figure 12 is a lengthwise cross sectional view of the oxide isolated transistor. From this figure it can be seen that the limiting factor of the size of the transistor is the metal interconnects and the spacing between the metal.

## NOISE CONSIDERATIONS

When a digital system is being designed, the designer works with a perfect mathematical system. Once the designer starts to layout his design he enters the real world where everything is not perfect. There are pitfalls in the laying out circuits that will make a perfectly good logic circuit work incorrectly and unpredictably. One of the major considerations in the layout of a circuit is noise. Noise is extraneous currents and voltages introduced into or produced by the circuit. When slower circuits are used consideration of noise is not as important as it is for fast circuits such as the Advanced Logic families. This is true because the slower circuits take longer to respond to noise and characteristically noise is pulses of short duration. The Advanced Logic families have addressed noise produced by the device itself, as mentioned previously, so it will not be addressed here. Noise can be introduced by several methods: external to the system, cross talk between lines, power supply spikes and line reflections. Each of these problems will be examined and solutions presented.

## NOISE MARGIN

Each logic family has a certain amount of noise margin. Noise margin is the voltage amplitude of an extraneous signal that can be added to the input level of a logic circuit before change in the output logic voltage level could occur. Worst case noise margin is defined as the difference between the minimum high voltage $\left[\mathrm{V}_{\mathrm{OH}}(2.5 \mathrm{~V})\right]$ minus the maximum input high voltage $\left[\mathrm{V}_{\mathrm{IH}}(2 \mathrm{~V})\right]$ or the maximum input low voltage [ $\mathrm{V}_{\text {IL }}(0.8 \mathrm{~V})$ ] minus the maximum output low voltage $\left[\mathrm{V}_{\mathrm{OL}}(0.5 \mathrm{~V})\right]$ whichever is smaller. For the ALS and AS families these numbers turn out to be 0.5 and 0.3 volts respectively.

## POWER SUPPLY SPIKES

Power supply spikes can be introduced to the system externally or generated internally. As gates switch from one logic state to another, their current drain on the supply will change. The more gates that switch at the same time the greater the current drain on the supply will be. The speed of the changes is also a factor as will be demonstrated. These current changes produce voltage variations because of supply line resistance and inductance.
In most designs the supply lead inductance is the dominant factor. For a current change di in time dt with a lead inductance of $L$, the resulting noise voltage is defined as $V=$ L[di/dt]. For a octal ALS buffer the current change can be 10 mA , the transition time can be 3 ns , and for a 15 cm line on a printed circuit board the inductance can be $0.1 \mu \mathrm{H}$. This will give a noise pulse of 333 mV . With several circuits switching at the same time this could produce a problem.
The solution to the problem is to include several decoupling capacitors evenly distributed around the board. Ceramic disc capacitors of $0.01 \mu \mathrm{~F}$ are often used. If a $0.01 \mu \mathrm{~F}$ capacitor is used in the above example the noise pulse would be greatly reduced. For a capacitor C and a current change di in the time dt the voltage change is represented by $\mathrm{V}=$ [(di) (dt)]/C. This gives a noise pulse of 3 mV . Usually one capacitor for every five ICs is sufficient. If more high power ICs (buffers and line drivers) are used a one to one ratio of capacitor to ICs might be required. Since the transition time of AS devices is so fast, each IC should have a bypass capacitor. These capacitors are inexpensive and will greatly increase the reliability of your design.

## LINE REFLECTIONS

Line reflection is another source of noise. Line reflection is caused by a difference in the impedance of the transmission line and the resistance of the line load. Each transmission line has a characteristic impedance which is the initial resistance seen by a signal entering the line.
Lets consider a simple circuit which includes a voltage source, a switch, a transmission line and a resistive load. The characteristic impedance of the transmission line is $\mathrm{Z}_{0}$ and the resistive load is R. The resistive load, R, can be referred to as the terminating resistance. When the switch is closed the initial current flowing into the line will be $I=$ $\mathrm{V} / \mathrm{Z}_{\mathrm{o}}$. A current step of magnitude I and voltage step of V flows down the transmission line. The current required by the load at the end of the transmission line is V/R. If the characteristics impedance of the transmission line does not equal the load resistance a partial reflection of the signal will occur.
One can define a reflection coefficient (Rho) as the reflected voltage amplitude divided by the incident voltage amplitude. It can be mathematically shown that the Rho $=[R-$ $\left.Z_{0}\right] /\left[R+Z_{0}\right]$. If $R$ equals 0 (short circuit) the Rho equals -1 . If $R$ equals infinity (open circuit) the Rho equals 1 . If $R$ $=Z_{0}$ the Rho equals 0 which indicates that there will be no reflection. The magnitude of the voltage at the load resistance is initially $\mathrm{V}(1+R h o)$. If a reflection initially occurs, further reflections will occur until $I=V / R$. Possible waveforms are shown in Figure 13.

It can be shown that the duration of each reflection is equal to twice the time it takes for the signal to propagate down the transmission line. Generally, gates do not respond to a signal that is shorter than the propagation delay of device itself. A good rule of thumb to use to determine if a transmission line requires termination is if the time required for the signal to propagate down the transmission line is greater than one quarter of the propagation delay of the device the line should be terminated.
Lets calculated the maximum line length for some Advanced Logic family devices. Lets assume that the signal travels down the line at the speed of light ( $3 \times 10$ to the eight $\mathrm{m} / \mathrm{s}$ ). The maximum line length is the speed of light times one quarter the propagation delay of the device. The propagation delay of an ALS gate is about 4 ns . This would give a safe maximum length of the line of 0.3 m (about 1 ft ). The propagation delay of an AS gate is about 2 ns . This would give a safe maximum length of the line of 0.15 m (about 0.5 ft ).
Another method of termination of a transmission line is a series termination. It can be shown that the initial step received at an open circuit termination is twice the input step.

If we have a series resistor at the transmitter that is equal to the characteristic impedance of the line the reflection would be absorbed by the series resistance. This method requires a high impedance receiver but uses less power than the previous method.

## CROSS TALK

Cross talk is the coupling of a signal from one line to an adjacent line. It is caused by the mutual inductance and capacitance between signal lines. Long parallel lines are the most susceptible to this problem. To minimize the effects of cross talk, proper shielding, grounding and decoupling should be done. On lines which may be particularly sensitive to cross talk, the distance between these lines should be increased.
Use flat cable with alternate signal/ground wires, coaxial cable, signal lines (PCB track) above ground plane with the minimum distance between lines equal to the distance between ground plane and signal plane, or twisted pairs to minimize cross talk.

## Unused Inputs

Unused inputs which are left open circuited can be a source of noise. An open circuited input settles at the threshold voltage of that node. It can act as an antenna and accept a signal. To avoid this problem any unused input should be tied to a potential that will not cause a logic error. For example, unused inputs of AND gates, NAND gates, and active low presets and clears of flip-flops should be tied to a high potential. Unused inputs of NOR gates should be tied to ground. Unused inputs that are tied to a high potential can be connected directly to the supply voltage as long as the 5.5 V maximum is not exceeded. A better method is to connect unused inputs to a high potential through a resistor ( $1 \mathrm{k} \Omega$ or greater) to the supply voltage. This will give some protection in case this input is shorted to ground. Several inputs can be connected to this resistor.

## Open-Collector Outputs

All open collector outputs, whether used alone or in a wiredOR configuration, requires an external pull-up resistor. The resistor value is dependent upon the fanout of the OR tie and the number of devices in the OR tie. $\mathrm{R}(\mathrm{min})$ is determined so that if only one output is LOW the maximum allowable OR tie fanout is not surpassed. The R(max) value is calculated with all the OR tied outputs HIGH to sustain the necessary $\mathrm{V}_{\mathrm{OH}}$.

$$
\begin{aligned}
& N=\# \text { of wired-OR outputs } \\
& R_{(\text {min })}=\frac{V_{C C(\text { max })}-V_{O L}}{I_{O L}-M \times I_{I L}} \\
& R_{(\text {max })}=\frac{V_{C C(\min )}-V_{O H}}{N \times I_{O H}+M \times I_{I H}}
\end{aligned}
$$

$M=\#$ of inputs being driven
$\mathrm{I}_{\mathrm{IL}}=$ LOW level input current
$\mathrm{I}_{\mathrm{H}}=\mathrm{HIGH}$ level input current
$\mathrm{V}_{\mathrm{OL}}=$ output LOW voltage ( 0.5 V )
$\mathrm{V}_{\mathrm{OH}}=$ output HIGH voltage (2.5)
$\mathrm{I}_{\mathrm{OL}}=$ LOW level fanout current
$\mathrm{I}_{\mathrm{OH}}=\mathrm{I}_{\mathrm{CEX}}=$ output HIGH current
Example: Two ALS03 gate outputs driving three LS gates.

$$
\begin{aligned}
& R_{(\text {min })}=\frac{5.25 \mathrm{~V}-0.5 \mathrm{~V}}{8 \mathrm{~mA}-3 \times 0.4 \mathrm{~mA}}=698 \Omega \\
& R_{(\max )}=\frac{4.75 \mathrm{~V}-2.5 \mathrm{~V}}{2 \times 0.1 \mathrm{~mA}+3 \times 0.02 \mathrm{~mA}}=16 \mathrm{k} \Omega
\end{aligned}
$$

The R range for the pull-up is between 698 and $16 \mathrm{k} \Omega$. The lower resistor values will provide faster speeds while the higher resistances give lower power dissipation.

## SUMMARY

- Pin compatible with other 5V bipolar families
- Faster propagation delays
- Lower power consumption
- Better selection of octal bus transceivers, transparent latches, and D-type flip-flops
- Addition of series of line drivers
- Addition of series of buffers
- Dynamic characteristics specified over supply voltage and temperature range
- Improved input threshold voltage
- Improved ESD protection
- Better pin-to-pin isolation
- Elimination of decoding glitches

## ALS/AS Functional Index/Selection Guide

"Several methods are used to represent typical values. For propagation delay typical values, the average of the typical values of the two delays are used. $\left[\frac{t_{\text {PHLTTYP }}+t_{\text {PLH }}(T Y P)}{2}\right]$

For power dissipation, the average of the typical values of current for all states the outputs can achieve is used ( $\mathrm{ICCL}^{\prime}, \mathrm{I}_{\mathrm{CCH}}$, $\mathrm{I}_{\mathrm{CCz}}$.) This current value is multiplied by nominal supply voltage ( 5 V ), and in some cases divided by the number of gates, bits, etc. All other typical values are singular typicals.

## DC Operating Conditions and Characteristics

## GENERAL DEFINITIONS

i: Current is the flow of electric charge from one potential to another through a conductor. The unit of measure is the Ampere, or Amp, abbreviated A. One Amp is equal to the current flowing through one ohm of resistance when one volt is applied across that resistance. Common units found in the semiconductor industry are the milliampere, abbreviated mA , equal to 0.001 A and the microampere, abbreviated $\mu \mathrm{A}$, equal to 0.000001 A . Negative current is defined as current flowing out of a device terminal and positive current is defined as current flowing into a device terminal.
V: Voltage, or the electromotive force which causes current to flow through a conductor. One Ampere of current flowing through one ohm of resistance develops a potential difference of one volt across that resistance. The unit of measure is the Volt, abbreviated V , and a common unit is the millivolt, abbreviated mV , equal to 0.001 V .

## input Current parameters

। Maximum High Level Input Current: Current flowing into an input when that input has the maximum voltage specified for the family applied to it. This test is used to guarantee the minimum reverse breakdown voltage of the input structure.
$\mathbf{I}_{\mathbf{I H}}$ High Level Input Current: The current flowing into an input when that input has a high level voltage equal to the minimum high level output voltage specified for the family. This test is used to check the emitter-to-emitter leakage and the inverse transistor action of a multi-emitter transistor input, the input leakage of a diode, PNP transistor, or C-B short type of input, and to guarantee the fan-in specified for the family.
$I_{\text {IK }}$ Input Clamp Current: The current flowing out of an input when that input is pulled below ground. This test is used to guarantee the integrity of the input clamp diode. The input clamp diode is used to limit the voltage swings on the input by clamping the negative excursions to a level equal to one diode drop below ground. This serves to reduce ringing on an incoming signal. Pulling the input below ground for an extended length of time can cause parasitic transistor action to occur between adjacent tanks on the die which can cause erroneous data to occur on the outputs of the device. To prevent this, voltages on the inputs during operation (other than high speed ringing) should be limited to no more than 0.5 V below ground at all times.
IIL Low Level Input Current: The current flowing out of an input when a low level voltage equal to the maximum low level output voltage specified for the family is applied to the input. This test is used to check the input pullup resistor on an MET or a diode input and to guarantee the specified fanin of the family.
$l_{T}+$ Current at Positive-Going Threshold Point: The current flowing out of a transition-operated (Schmitt trigger) input when a voltage equal to the positive going threshold voltage is applied to the input.
$\mathrm{l}_{\mathbf{T}}$ - Current at Negative-Going Threshold Point: The current flowing out of a transition-operated (Schmitt trigger) input when a voltage equal to the negative going threshold voltage is applied to the input.

## OUTPUT CURRENT PARAMETERS

ICEX Output Leakage Current: The current flowing into an open collector output when input conditions have been applied that, according to the product specification, will cause the output to be in the logic high state. This test checks the reverse breakdown of the output transistor.
Io(off) Off-State Output Current: The current flowing into an output with input conditions applied that, according to the product specification, will cause the output switching element to be in the off state.
NOTE: This parameter is usually specified for open collector outputs intended to drive devices other than logic circuits, such as displays. Any leakage current applied to a display may cuase the display to be activated.

IOH High Level Output Current: The current flowing out of an output with input conditions applied that, according to the product specification, will establish a logic high level at the output. This test guarantees the current sourcing (drive) capability of the output and the fan-out specified for the family. IOL Low Level Output Current: The current flowing into an output with input conditions applied that, according to the product specification, will establish a logic low level at the output. This test guarantees the current sinking capability of the output and the fan-out specified for the family.
Ios Output Short-Circuit Current: The current out of an output when that output is shorted to ground, or another specified potential, with input conditions applied that, according to the product specification, will establish a logic high level at the output.
IOz High-Impedance State Output Current: These tests guarantee that the device will not excessively load a bus line when the device output is put into the TRI-STATE ${ }^{\circledR}$ mode.
$I_{\text {OZH }}$ (or $I_{\text {SINK }}$ ): The current flowing into an output with input conditions applied to the output control pin such that the output is in the high impedance state and input conditions applied to the other inputs that, according to the product specification, will establish a logic low level at the output.
IOZL(or ISOURCE): The current flowing out of an output with input conditions applied to the output control pin such that the output is in the high impedance state and input conditions applied to the other inputs that, according to the product specification, will establish a logic high level at the output.

## SUPPLY CURRENT PARAMETERS

$I_{\mathbf{C C H}}$ Supply Current (outputs in the high state): The current flowing into the $V_{C C}$ terminal of a device with input conditions applied that, according to the product specification, will establish a logic high level at the output(s).
ICCL Supply Current (outputs in the low state): The current flowing into the $\mathrm{V}_{\mathrm{CC}}$ terminal of a device with input conditions applied that, according to the product specification, will establish a logic low level at the output(s).

## DC Operating Conditions and Characteristics (Continued)

Iccz Supply Current (outputs in the high-impedance state): The current flowing into the $V_{C C}$ terminal of a device with input conditions applied that, according to the product specification, will establish a high impedance state at the output.

## INPUT VOLTAGE PARAMETERS

$B V_{I N}$ Input Breakdown Voltage: The maximum voltage that the device is guaranteed to be able to withstand without exceeding the maximum input current specification.
$V_{F}$ Input Forward Voltage: The voltage applied to the input of a device that causes the input structure to become forward biased; usually equal to the maximum output low voltage specified for the family.
$\mathbf{V}_{I H}$ High Level Input Voltage: The minimum positive voltage level that can be applied to an input terminal of a device and be recognized as a logic high level.
$\mathbf{V}_{\mathbf{I K}}$ Input Clamp Voltage: The input clamp voltage specification checks the quality of the input diode whose purpose is to damp out ringing. This is not intended to be an operating condition and if this voltage is allowed to persist for any length of time, parasitic transistor action will occur between adjacent geometry tanks and circuit performance will be degraded, in some cases to the point of failure.
$\mathbf{V}_{\text {IL }}$ Low Level Input Voltage: The maximum positive voltage level that can be applied to an input terminal of a device and be recognized as a logic low level.
$\mathbf{V}_{\mathbf{R}}$ Input Reverse Voltage: The voltage applied to an input of a device that causes the input structure to become reverse biased; usually equal to the minimum high level output voltage specified for the family.
$\mathbf{V}_{\mathrm{T}}+$ Positive-Going Threshold Voltage: The voltage level at a transition-operated (Schmitt trigger) input that causes operation of the logic element according to specification as the input voltage rises from a level below the negative-going threshold voltage, $\mathrm{V}_{\mathrm{T}}$ -
$\mathbf{V}_{\mathbf{T}}-$ Negative-Going Threshold Voltage: The voltage level at a transition-operated (Schmitt trigger) input that causes operation of the logic element according to specification as the input voltage falls from a level above the positive-going threshold voltage, $\mathrm{V}_{\mathrm{T}}+$.

## OUTPUT VOLTAGE PARAMETERS

$V_{O H}$ High Level Output Voltage: The voltage at an output terminal with input conditions applied that, according to the product specification, will establish a high level at the output.
Vol Low Level Output Voltage: The voltage at an output terminal with input conditions applied that, according to the product specification, will establish a low level at the output.
$V_{0}$ (off) Off-State Output Voltage: The voltage at an output terminal with input conditions applied that, according to the product specification, will cause the output switching element to be in the off state.
NOTE: This characteristic is usually specified only for outputs without internal pull-up elements intended for driving devices other than logic circuits.
$V_{0}(o n)$ On-State Output Voltage: The voltage at an output terminal with input conditions applied that, according to the product specification, will cause the output switching element to be in the on state.
NOTE: This characteristic is usually specified only for outputs without internal pull-up elements intended for driving devices other than logic circuits.

## AC Operating Conditions and Characteristics

## INPUT PARAMETERS

$\mathrm{f}_{\text {MAX }}$ Maximum Clock Frequency: The highest rate at which the clock input of a bistable circuit can be driven through its required sequence while maintaining stable transitions of logic levels at the output with input conditions established that should cause changes of output logic level in accordance with the specification. Unless otherwise specified, this test is performed with no restrictions on input rise and fall times or duty cycle.
NOTE: A minimum value is specified that is the highest frequency at which all devices are guaranteed to function correctly.
$t_{H}$ Hold Time: The interval during which a signal must be maintained at a given data input after an active transition at another given input.
NOTE: A minimum value is specified that is the smallest time interval above which all devices are guaranteed to function correctly.
tw Pulse Width: The time interval between specified voltage reference points on the leading and trailing edges of a pulse waveform.
NOTE: A minimum value is specified that is the smallest time interval at which correct operation of the logic element is guaranteed.
$t_{\text {REC }}$ Recovery Time: The time interval needed to switch a memory-type device from a write mode to a read mode and to obtain valid data signals at the output.
NOTE: A minimum value is specified that is the smallest time interval at which correct operation of the device is guaranteed.
$t_{\text {REL }}$ Release Time: The time interval between one control input going inactive and another input going active after which the inactive input no longer has any influence on the device operation.
NOTE: A minimum value is specified that is the smallest time interval at which correct operation of the logic element is guaranteed.
ts Set-Up Time: The time interval during which a stable signal must be maintained at a specified input terminal before an active transition at another specified input terminal.
NOTE: A minimum value is specified that is the smallest time interval at which correct operation of the logic element is guaranteed.
$t_{\mathbf{R}}$ Rise Time: The time interval between a specified lowlevel voltage and a specified high-level voltage on a waveform that is changing from a defined low level to a defined high level. Common defined levels are from $10 \%$ of the signal amplitude to $90 \%$ of the signal amplitude.
$t_{\mathbf{F}}$ Fall Time: The time interval between a specified high-level voltage and a specified low-level voltage on a waveform that is changing from a defined high level to a defined low level. Common defined levels are from $90 \%$ of the signal amplitude to $10 \%$ of the signal amplitude.

## OUTPUT PARAMETERS

$t_{\text {pzH }}$ Output Enable Time to a High Logic Level: The propagation delay time between the specified voltage reference points on the input and output waveforms with a TRISTATE output changing from a high impedance (off) state to the defined high state.
$t_{\text {pzL }}$ Output Enable Time to a Low Logic Level: The propagation delay time between the specified voltage reference points on the input and output waveforms with a TRI-STATE output changing from a high impedance (off) state to the defined low state.
$\mathbf{t}_{\text {PHZ }}$ Output Disable Time from a High Logic Level: The propagation delay time between the specified voltage reference points on the input and output waveforms with a TRISTATE output changing from the defined high state to the high impedance (off) state .
t plz Output Disable Time from a Low Logic Level: The propagation delay time between the specified voltage reference points on the input and output waveforms with a TRISTATE output changing from the defined low state to the high impedance (off) state.
$t_{\text {wout Out }}$ Out Pulse Width: The time interval between specified voltage reference points on the leading and trailing edges of an output waveform.
NOTE: This is usually only specified for monostable elements.
$t_{\text {plh }}$ Propagation Time, Low to High: The time between the specified voltage reference points on the input and output waveforms with the output changing from a low logic level to a high logic level.
$t_{\text {PHL }}$ Propagation Delay, High to Low: The time between the specified voltage reference points on the input and output waveforms with the output changing from a high logic level to a low logic level.
$\mathbf{t}_{\mathrm{TLH}}, \mathrm{t}_{\mathbf{r}}$ Transition Time, or Rise Time: The time interval between a specified low-level voltage and a specified highlevel voltage on a waveform that is changing from a defined low level to a defined high level. Common defined levels are from $10 \%$ of the signal amplitude to $90 \%$ of the signal amplitude, or from 0.6 V to 2.6 V .
$t_{\text {THL }}, t_{f}$ Transition Time, or Fall Time: The time interval between a specified high-level voltage and a specified lowlevel voltage on a waveform that is changing from a defined high level to a defined low level. Common defined levels are from $90 \%$ of the signal amplitude to $10 \%$ of the signal amplitude, or from 2.6 V to 0.6 V .
Note A: All AC Specifications are for one output switching at a time.

## EXPLANATION OF DEVICE FUNCTIONS

## Circuit Complexity

SSI: Small Scale Integration; the lowest level of complexity in integrated circuits.
MSI: Medium Scale Integration; small subsystems integrated into a single microcircuit.
LSI: Large Scale Integration; large subsystems or small systems integrated into a single microcircuit.

## FUNCTIONAL DESCRIPTIONS

Buffer: A logic gate with high output drive capability, or fanout. Buffers are used where a single circuit must drive a large number of loads.
Comparator: A logic circuit that will compare two separate input signals and produce an output based on that comparison. A simple comparator is the Exclusive-NOR gate, which produces a high level output only when its two inputs are identical.
Counter: A logic circuit that counts the number of input pulses it receives. Counters can be used for frequency division, counting, and sequencing digital operations. Common counter configurations are Binary, where the device counts from 0 to 15 and Decade, where the device counts from 0 to 9 .

## AC Operating Conditions and Characteristics (Continued)

Data Selector/Multiplexer: A logic circuit that will select one of several input signals and feed that signal onto a common bus line. It can be thought of as a multipole, multiposition switch with each switch pole representing one output and each switch position representing one input.
Decoder/Demultiplexer: A logic circuit that is the complement of the Data Selector/Multiplexer; that is, this circuit takes an input signal and feeds it to any one of several output lines depending on the information placed on its steering, or control, inputs.
Driver: Same as Buffer, above.
Flip-Flop: A logic circuit that is used to store information. A flip-flop is called "bistable" since it has two stable states.
Gate: The basic building block of all logic circuits; an element whose output is a Boolean function of its inputs. The basic functions are the AND, OR, and NOT. By combining these functions, NAND, NOR, and Exclusive-OR and Exclu-sive-NOR gates are built.
Latch: A bistable element that latches, or holds, data which is present at its input at the time the Enable input goes to its inactive state. When the Enable input is active, the data, present at the input, is passed directly to the output, similar to the operation of a gate.
One-Shot: Monostable multivibrator; a flip-flop that only has one stable state. When triggered by an input transient, it flips to its unstable state for a time period determined by an external R-C network connected to its timing inputs, and then returns to its stable state.
Shift Register: A series of flip-flops in which the data signal is shifted out of one flip-flop and into the succeeding flip-flop during an active transition on the clock input.
Transceiver: A logic circuit that can transmit data onto a bus line and receive data off of the bus line using the same terminal as an input and output. The direction of signal flow is determined by logic levels present at a Direction Control input.

## OTHER TERMS

Asynchronous: A mode of operation that does not require any specific timing relationship between different control inputs.
Open Collector: Output configuration that has no internal pullup. This configuration enables outputs that are connected together (wired-OR) to assume opposite states without incurring damage.
Schmitt Trigger: An input configuration that has a different threshold point depending on whether the input signal is rising or falling. This is especially useful in electrically noisy environments.
Synchronous: A mode of operation where specific timing requirements must be met between control inputs before an indicated action can occur.
Totem Pole: An output configuration that contains an internal pullup structure, usually a transistor pullup allowing higher output drive capability than is available with open collector outputs.

TRI-STATE: A registered trademark for a circuit configuration in which the device can be switched 'off' during which time the output presents a very high impedance to the bus it is connected to. This allows multiple outputs to be connected to a bus line while only one output drives the line, the other outputs being switched into their high impedance states.

## EXPLANATION OF FUNCTION TABLES

The following symbols are used in the function tables found in NSC data sheets:

H = high logic level (steady state)
$\mathrm{L} \quad=$ low logic level (steady state)
$\uparrow \quad=$ transition from low to high logic level
$\downarrow \quad=$ transition from high to low logic level
$\mathrm{X} \quad=$ irrelevant (any level, including transitions)
$Z \quad=$ off (high impedance) state of a TRI-STATE output
a...h $=$ the level of steady state inputs at inputs $A$ through H respectively
$Q_{0} \quad=$ the level of $Q$ before the indicated steady state input conditions were established
$\bar{Q}_{0} \quad=$ complement of $Q_{0}$ or level of $Q$ before the indicated steady state input conditons were established
$Q_{n} \quad=$ level of $Q$ before the most recent active transition indicated by $\uparrow$ or $\downarrow$
$\Omega \quad=$ one high level pulse
Ч = one low level pulse
toggle $=$ each output changes to the complement of its previous level on each active transition indicated by $\uparrow$ or $\downarrow$
If, in the input columns, a row contains only the symbols H , L , and/or X , this means the indicated output is valid whenever the input configuration is achieved regardless of the sequence in which it is achieved. The output persists so long as the input configuration is maintained.
If, in the input columns, a row contains H , L , and/or X together with $\uparrow$ and/or $\downarrow$, this means the output is valid whenever the input configuration is achieved but the transition(s) must occur following the achievement of the steady state levels. If the output is shown as a level ( $H, L, Q_{0}$, or $\bar{Q}_{0}$, it persists so long as the steady state input levels and the levels that terminate indicated transitions are maintained. Unless otherwise indicated, input transitions in the opposite direction to those shown have no effect on the output. If the output is shown as a pulse, $\Omega$ or $Ч$, the pulse follows the indicated input transition and persists for an interval dependent on the circuit.
Among the most complex function tables in this book are those of the shift registers. These embody most of the symbols used in any of the function tables, plus more. As an example, Figure 1 is the function table for a 4-bit bidirectional universal shift register, similar to the DM54LS194.
The first line of the table represents "asynchronous" clearing of the register and indicates that if CLEAR is low, all four outputs will be reset low regardless of the states of the other inputs. In the succeeding lines, CLEAR is inactive (high) and consequently has no effect.

## AC Operating Conditions and Characteristics (Continued)

The second line indicates that so long as the CLOCK input remains low (while CLEAR is high), no other input has any effect and the outputs maintain the levels they assumed before the steady-state combination of CLEAR high and CLOCK low was established. Since on all the other lines of the table only the rising edge of the CLOCK is shown to be active, the second line implicitly shows that no further change in the outputs will occur while the CLOCK remains high or on the high-to-low transition of the CLOCK.
The third line of the table represents "synchronous" parallel loading of the register and indicates that if S1 and S0 are both high, then regardless of the levels at the SERIAL inputs, the data present at $A$ will transfer to $Q A$, the data present at B will transfer to QB, and so forth, following a low-to-high transition on CLOCK.
The fourth and fifth lines represent the "synchronous" loading of high and low level data, respectively, from the SHIFT RIGHT SERIAL input and the shifting one bit to the right of previously entered data; data previously at QA is now at QB, data previously at QB and QC is now at QC and QD respec-
tively, and the data previously at QD has been shifted out of the register. This entry of data and shifting takes place on the low-to-high level transition of CLOCK when S1 is low and SO is high and as shown, the levels at the PARALLEL inputs, A through D, have no effect.
The sixth and seventh lines represent the "synchronous" loading of high and low level data respectively, from the SHIFT LEFT SERIAL input and the shifting one bit to the left of previously entered data; data previously at QD is now at QC, data previously at QC and QB is now at QB and QA respectively, and the data previously at QA has been shifted out of the register. This entry of serial data and shifting to the left takes place on the low-to-high level transition of CLOCK when S1 is high and S0 is low and as seen, the levels at the PARALLEL inputs, A through D, have no effect.
The last line indicates that so long as both MODE inputs are low, no other input has any effect and, as in the second line, the outputs maintain the levels they assumed before the steady state combination of CLEAR high and both MODE inputs low was established.

| Clear | Mode |  | Inputs |  |  |  |  |  |  | Outputs |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Clock | Serial |  | Parallel |  |  |  |  |  |  |  |
|  | S1 | So |  | Left | Right | A | B | C | D | $\mathbf{Q}_{\mathbf{A}}$ | $\mathbf{Q}_{B}$ | $Q_{C}$ | $\mathbf{Q}_{\mathrm{D}}$ |
| L | X | $x$ | X | X | $X$ | X | X | X | X | L | L | L | L |
| H | X | X | L | X | X | X | X | X | X | $Q_{A 0}$ | $\mathrm{Q}_{\mathrm{BO}}$ | $Q_{\text {co }}$ | $Q_{D 0}$ |
| H | H | H | $\uparrow$ | X | X | a | b | c | d | a | b | c | d |
| H | L | H | $\uparrow$ | X | H | X | X | X | X | H | $Q_{\text {An }}$ | $Q_{B n}$ | $Q_{C n}$ |

DM54ALS00A/DM74ALS00A
Quad 2-Input NAND Gate

## General Description

This device contains four independent gates, each of which performs the logic NAND function.

## Features

■ Switching specifications at 50 pF

- Switching specifications guaranteed over full temperature and $V_{C C}$ range

■ Advanced oxide-isolated, ion-implanted Schottky TTL process

- Functionally and pin for pin compatible with Schottky and low power Schottky TTL counterpart
- Improved AC performance over Schottky and low power Schottky counterparts

## Connection Diagram

Dual-In-Line Package

Order Number DM54ALS00AJ, DM74ALS00AM, DM74ALS00AN or DM74ALS00ASJ
See NS Package Number J14A, M14A, M14D or N14A

## DM74ALS01 Quad 2-Input <br> NAND Gate with Open-Collector Outputs

## General Description

This device contains four independent gates, each of which performs the logic NAND function. The open-collector outputs require external pull-up resistors for proper logical operation.

## Pull-Up Resistor Equations

$$
\begin{aligned}
& R_{\mathrm{MAX}}=\frac{V_{\mathrm{CC}}(\mathrm{Min})-V_{\mathrm{OH}}}{N_{1}\left(I_{\mathrm{OH}}\right)+N_{2}\left(I_{\mathrm{IH}}\right)} \\
& R_{\mathrm{MIN}}=\frac{V_{\mathrm{CC}}(\mathrm{Max})-V_{\mathrm{OL}}}{I_{\mathrm{OL}}-N_{3}\left(I_{I L}\right)}
\end{aligned}
$$

Where: $\quad N_{1}\left(l_{\mathrm{OH}}\right)=$ total maximum output high current for all outputs tied to pull-up resistor
$\mathrm{N}_{2}\left(l_{\mid H}\right)=$ total maximum input high current for all inputs tied to pull-up resistor
$N_{3}\left(l_{L}\right)=$ total maximum input low current for all inputs tied to pull-up resistor

## DM74ALS03B Quad 2-Input

## NAND Gate with Open Collector Outputs

## General Description

This device contains four independent gates, each of which performs the logic NAND function. The open-collector outputs require external pull-up resistors for proper logical operation.

## Pull-Up Resistor Equations

$$
\begin{aligned}
& R_{\mathrm{MAX}}=\frac{V_{C C}(\mathrm{Min})-V_{\mathrm{OH}}}{N_{1}\left(I_{O H}\right)+N_{2}\left(I_{\mathrm{IH}}\right)} \\
& \mathrm{R}_{\mathrm{MIN}}=\frac{V_{\mathrm{CC}}(\mathrm{Max})-V_{\mathrm{OL}}}{I_{\mathrm{OL}}-N_{3}\left(\mathrm{I}_{\mathrm{ILL}}\right)}
\end{aligned}
$$

Where: $\quad \mathrm{N}_{1}\left(\mathrm{I}_{\mathrm{OH}}\right)=$ total maximum output high current for all outputs tied to pull-up resistor
$\mathrm{N}_{2}\left(\mathrm{I}_{1 \mathrm{H}}\right)=$ total maximum input high current for all inputs tied to pull-up resistor
$N_{3}\left(l_{1 L}\right)=$ total maximum input low current for all inputs tied to pull-up resistor

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with Schottky and low power Schottky TTL counterpart
- Improved AC performance over Schottky and low power Schottky counterparts

## Connection Diagram

## DM74ALS09 Quad 2-Input AND Gate with Open Collector Outputs

## General Description

This device contains four independent gates, each of which performs the logic AND function. The open-collector outputs require external pull-up resistors for proper logical operation.

## Pull-Up Resistor Equations

$$
\begin{aligned}
& R_{\mathrm{MAX}}=\frac{V_{\mathrm{CC}}(\mathrm{Min})-V_{\mathrm{OH}}}{N_{1}\left(I_{\mathrm{OH}}\right)+N_{2}\left(I_{\mathrm{IH}}\right)} \\
& \mathrm{R}_{\mathrm{MIN}}=\frac{V_{\mathrm{CC}}(\mathrm{Max})-V_{\mathrm{OL}}}{I_{\mathrm{OL}}-N_{3}\left(\mathrm{I}_{\mathrm{IL}}\right)}
\end{aligned}
$$

Where: $\quad N_{1}\left(l_{\mathrm{OH}}\right)=$ total maximum output high current for all outputs tied to pull-up resistor
$\mathrm{N}_{2}\left(\mathrm{l}_{\mathrm{IH}}\right)=$ total maximum input high current for all inputs tied to pull-up resistor
$N_{3}\left(I_{I L}\right)=$ total maximum input low current for all inputs tied to pull-up resistor

## Features

m Switching specifications at 50 pF

- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with Schottky and low power Schottky TTL counterpart
- Improved AC performance over Schottky and low power Schottky counterparts

## DM74ALS13 Dual 4-Input <br> NAND Gate with Schmitt Trigger Inputs

## General Description

This device contains two independent gates, each of which performs the logic NAND function. Each input has hysteresis which increases the noise immunity and transforms a slowly changing input signal to a fast changing, jitter-free output.

## Features

- Switching specification at 50 pF

■ Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin-for-pin compatible with Schottky and Low Power Schottky TTL counterparts
- Improved AC performance over low power Schottky counterpart

## Connection Diagram

## Function Table

$\mathbf{Y}=\overline{\mathbf{A B C D}}$

| Inputs |  |  |  |  |

## DM74ALS15A Triple 3-Input <br> AND Gate with Open Collector Outputs

## General Description

This device contains three independent gates, each of which performs the logic AND function. The open-collector outputs require external pull-up resistors for proper logical operation.

## Pull-Up Resistor Equations

$$
\begin{aligned}
& R_{\text {MAX }}=\frac{V_{C C}(\text { Min })-V_{O H}}{N_{1}\left(l_{O H}\right)+N_{2}\left(l_{\mathrm{IH}}\right)} \\
& R_{\text {MIN }}=\frac{V_{C C}(\mathrm{Max})-V_{\mathrm{OL}}}{I_{O L}-N_{3}\left(\mathrm{IIL}^{2}\right.}
\end{aligned}
$$

Where: $\quad N_{1}\left(l_{\mathrm{OH}}\right)=$ total maximum output high current for all outputs tied to pull-up resistor
$\mathrm{N}_{2}\left(\mathrm{I}_{\mathrm{IH}}\right)=$ total maximum input high current for all inputs tied to pull-up resistor
$N_{3}\left(l_{1 L}\right)=$ total maximum input low current for all inputs tied to pull-up resistor

## Features

■ Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
m Functionally and pin for pin compatible with Schottky and low power Schottky TTL counterpart

- Improved AC performance over Schottky and low power Schottky counterparts

## DM74ALS22B

Dual 4-Input NAND Gate with Open Collector Outputs

## General Description

This device contains two independent gates, each of which performs the logic NAND function. The open-collector outputs require external pull-up resistors for proper logical operation.

## Pull-Up Resistor Equations

$$
\begin{aligned}
& R_{M A X}=\frac{V_{C C}(\mathrm{Min})-V_{\mathrm{OH}}}{N_{1}\left(I_{O H}\right)+N_{2}\left(I_{I H}\right)} \\
& R_{\mathrm{MIN}}=\frac{V_{\mathrm{CC}}(\mathrm{Max})-V_{\mathrm{OL}}}{I_{\mathrm{OL}}-N_{3}\left(I_{\mathrm{IL}}\right)}
\end{aligned}
$$

Where: $\quad N_{1}\left(l_{\mathrm{OH}}\right)=$ total maximum output high current for all outputs tied to pull-up resistor
$\mathrm{N}_{2}\left(\mathrm{I}_{\mathrm{IH}}\right)=$ total maximum input high current for all inputs tied to pull-up resistor
$\mathrm{N}_{3}\left(\mathrm{l}_{1 L}\right)=$ total maximum input low current for all inputs tied to pull-up resistor

## Features

- Switching specifications at 50 pF .
- Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with Schottky and low power Schottky TTL counterpart
- Improved AC performance over Schottky and low power Schottky counterparts

## Connection Diagram

## DM54ALS32/DM74ALS32

Quad 2-Input OR Gate

## General Description

This device contains four independent gates, each of which performs the logic OR function.

## Features

m Switching specifications at 50 pF

- Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range

포 Advanced oxide-isolated, ion-implanted Schottky TTL process

- Functionally and pin for pin compatible with Schottky and low power Schottky TTL counterpart
- Improved AC performance over Schottky and low power Schottky counterparts

## Connection Diagram

Dual-In-Line Package

Order Number DM54ALS32J, DM74ALS32M, DM74ALS32N or DM74ALS32SJ See NS Package Number J14A, M14A, M14D or N14A

## DM74ALS33A Quadruple 2-Input NOR Buffer with Open-Collector Outputs

## General Description

This device contains four independent gates, each of which performs the logic NOR function. The open-collector outputs require external pull-up resistors for proper logical operation.

## Pull-Up Resistor Equations

$$
\begin{aligned}
& R_{\mathrm{MAX}}=\frac{V_{\mathrm{CC}}(\mathrm{Min})-V_{\mathrm{OH}}}{N_{\mathrm{t}}\left(\mathrm{I}_{\mathrm{OH}}\right)+N_{2}\left(I_{\mathrm{IH}}\right)} \\
& \mathrm{R}_{\mathrm{MIN}}=\frac{V_{\mathrm{CC}}(\mathrm{Max})-V_{\mathrm{OL}}}{I_{\mathrm{OL}}-N_{3}\left(I_{\mathrm{IL}}\right)}
\end{aligned}
$$

Where: $\quad N_{1}\left(l_{\mathrm{OH}}\right)=$ total maximum output high current for all outputs tied to pull-up resistor
$\mathrm{N}_{2}\left(I_{\mathrm{IH}}\right)=$ total maximum input high current for all inputs tied to pull-up resistor
$\mathrm{N}_{3}\left(\mathrm{l}_{\mathrm{LL}}\right)=$ total maximum input low current for all inputs tied to pull-up resistor

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range
E Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with LS TTL counterpart
- Improved AC performance over LS33
- Improved line receiving characteristics

## DM54ALS74A/DM74ALS74A Dual D Positive-Edge-Triggered Flip-Flop with Preset and Clear

## General Description

The 'ALS74A contains two independent positive edge-triggered flip-flops. Each flip-flop has individual D , clock, clear and preset inputs, and also complementary Q and $\overline{\mathrm{Q}}$ outputs.
Information at input $D$ is transferred to the $Q$ output on the positive going edge of the clock pulse. Clock triggering occurs at a voltage level of the clock pulse and is not directly related to the transition time of the positive going pulse. When the clock input is at either the high or low level, the D input signal has no effect.
Asynchronous preset and clear inputs will set or clear Q output respectively upon the application of low level signal.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
n Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin-for-pin compatible with Schottky and LS TTL counterpart
- Improved AC performance over LS74 at approximately half the power

## Connection Diagram

## Dual-In-Line Package

TL/F/6109-1
Order Number DM54ALS74AJ, DM74ALS74AM, DM74ALS74AN or DM74ALS74ASJ
See NS Package Number J14A, M14A, M14D or N14A

## DM74ALS109A Dual J-K Positive-Edge-Triggered Flip-Flop with Preset and Clear

## General Description

The DM54ALS109A is a dual edge-triggered flip-flop. Each flip-flop has individual J, $\overline{\mathrm{K}}$, clock, clear and preset inputs, and also complementary Q and $\overline{\mathrm{Q}}$ outputs.
Information at input J or $\overline{\mathrm{K}}$ is transferred to the Q output on the positive going edge of the clock pulse. Clock triggering occurs at a voltage level of the clock pulse and is not directly related to the transition time of the positive going pulse. When the clock input is at either the high or low level, the J, $\overline{\mathrm{K}}$ input signal has no effect.
Asynchronous preset and clear inputs will set or clear Q output respectively upon the application of low level signal. The J-K design allows operation as a $D$ flip-flop by tying the $J$ and $\bar{K}$ inputs together.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
m Functionally and pin for pin compatible with Schottky and LS TTL counterpart
- Improved AC performance over LS109 at approximately half the power

## Connection Liagram

Note 2: The output conditions have been chosen to produce a current that closely approximates one half of the true short circuit output current, los.

Note 1: See Section 1 for test waveforms and output load.

## Logic Diagram

TL/F/6196-2

National Semiconductor

## DM54ALS125/DM74ALS125 Quad TRI-STATE ${ }^{\circledR}$ Buffer

## General Description

This device contains four independent gates each of which performs a non-inverting buffer function. The outputs have the TRI-STATE feature. The TRI-STATE circuitry contains a feature that maintains the buffer outputs in TRI-STATE (high impedance state) during power supply ramp-up or rampdown. This eliminates bus glitching problems that arise during power-up and power-down.

## Features

Advanced low power oxide-isolated ion-implanted Schottky TTL process

- Functional and pin compatible with the DM54/74LS counterpart
■ Switching response specified into $500 \Omega$ and 50 pF load
- Switching response specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ supply range
- PNP input design reduces input loading
- Low level drive current:
$54 \mathrm{ALS}=12 \mathrm{~mA}, 74 \mathrm{ALS}=24 \mathrm{~mA}$

## Functional Table

| Input |  |  |
| :---: | :---: | :---: |
| A | C | Output |
| L | L | L |
| H | L | H |
| X | H | $\mathrm{Hi}-Z$ |

H = High Logic Level
$\mathrm{L}=$ Low Logic Level
$X=$ Either Low or High Logic Level
$\mathrm{Hi}-\mathrm{Z}=$ TRI-STATE (Outputs are disabled)

[^13] product without notice.

## DM74ALS131

3 to 8 Line Decoder/Demultiplexer with Address Register

## General Description

The ALS131 is a three-line to eight-line decoder/demultiplexer with registers on the three address inputs. When the clock transitions from low to high, the address present at the select inputs ( $A, B$, and $C$ ) is stored in the latches. The output enable controls, G1 and $\overline{\mathrm{G}} 2$, control the state of the outputs independently of the select or clock inputs. All of the outputs are high unless G 1 is high and $\overline{\mathrm{G}} 2$ is low. The ALS131 is ideally suited for implementing glitch-free decoders in strobed (stored-address) applications in bus-oriented systems.

## Features

- Combines decoder and 3-bit address register
- Incorporates 2 enable inputs to simplify cascading
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
m Advanced oxide-isolated, ion-implanted Schottky TTL process

## DM74ALS132 Quad 2-Input NAND Gate with Schmitt Trigger Inputs

## General Description

This device contains four independent gates, each of which performs the logic NAND function. Each input has hysteresis which increases the noise immunity and transforms a slowly changing input signal to a fast changing, jitter-free output.

## Features

- Switching specification at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin-for-pin compatible with Schottky and Low Power Schottky TTL counterparts
- Improved AC performance over low power Schottky counterpart

## DM74ALS136 Quad 2-Input Exclusive-OR Gate with Open-Collector Outputs

## General Description

This device contains four independent gates, each of which performs the logic exclusive-OR function. The open-collector outputs require external pull-up resistors for proper logical operation.

## Pull-Up Resistor Equations

$$
\begin{aligned}
& R_{M A X}=\frac{V_{C C}(\mathrm{Min})-V_{\mathrm{OH}}}{N_{1}\left(I_{\mathrm{OH}}\right)+N_{2}\left(I_{\mathrm{IH}}\right)} \\
& R_{\mathrm{MiN}}=\frac{V_{\mathrm{CC}}(\mathrm{Max})-V_{\mathrm{OL}}}{I_{\mathrm{OL}}-N_{3}\left(I_{\mathrm{IL}}\right)}
\end{aligned}
$$

Where: $\quad N_{1}\left(I_{\mathrm{OH}}\right)=$ total maximum output high current for all outputs tied to pull-up resistor
$\mathrm{N}_{2}\left(\mathrm{I}_{\mathrm{H}}\right)=$ total maximum input high current for all inputs tied to pull-up resistor
$\mathrm{N}_{3}\left(\mathrm{l}_{\mathrm{IL}}\right)=$ total maximum input low current for all inputs tied to pull-up resistor

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with LS TTL counterpart
- Improved AC performance over Schottky and low power Schottky counterparts

## DM74ALS137 3 to 8 Line <br> Decoder/Demultiplexer with Address Latches

## General Description

The ALS137 is a three line to eight line decoder/demultiplexer with latches on the three address inputs. When the latch-enable input (GL) is low, the ALS137 acts as a decoder/demultiplexer. When $\overline{\mathrm{GL}}$ goes from low to high, the address present at the select inputs ( $\mathrm{A}, \mathrm{B}$, and C ) is stored in the latches. Further address changes are ignored as long as GL remains high. The output enable controls, G1 and G2, control the state of the outputs independently of the select or latch-enable inputs. All of the outputs are high unless G1 is high and $\overline{\mathrm{G} 2}$ is low. The ALS137 is ideally suited for implementing glitch-free decoders in strobed (stored-address) applications in bus-oriented systems.

## Features

- Combines decoder and 3-bit address latch
- Incorporates 3 enable inputs to simplify cascading

■ Low power dissipation ....................... 28 mW typ

- Switching specifications guaranteed over full temperature and $V_{C C}$ range
e Advanced oxide-isolated, ion-implanted Schottky TTL process

## Logic Diagram

## DM54ALS138/DM74ALS138 3 to 8 Line Decoder/Demultiplexer

## General Description

These Schottky-clamped circuits are designed to be used in high-performance memory-decoding or data-routing applications, requiring very short propagation delay times. In high-performance memory systems these decoders can be used to minimize the effects of system decoding. When used with high-speed memories, the delay times of these decoders are usually less than the typical access time of the memory. This means that the effective system delay introduced by the decoder is negligible.
The ALS138 decodes one-of-eight lines, based upon the conditions at the three binary select inputs and the three enable inputs. Two active-low and one active-high enable inputs reduce the need for external gates or inverters when expanding. A 24 -line decoder can be implemented with no external inverters, and 32 -line decoder requires only one inverter. An enable input can be used as a data input for demultiplexing applications.

This decoder/demultiplexer features fully buffered inputs, presenting only one normalized load to its driving circuit. All inputs are clamped with high-performance Schottky diodes to suppress line-ringing and simplify system design.

## Features

- Designed specifically for high speed: Memory decoders Data transmission systems
■ 3- to 8 -line decoder incorporates 3 enable inputs to simplify cascading and/or data reception
- Low power dissipation . . 23 mW typ

■ Switching specifications guaranteed over full temperature and $V_{C C}$ range

- Advanced oxide-isolated, ion-implanted Schottky TTL process

## DM54ALS151/DM74ALS151 1 of 8 Line Data Selector/Multiplexer

## General Description

This Data Selector/Multiplexer contains full on-chip decoding to select one-of-eight data sources as a result of a unique three-bit binary code at the Select inputs. Two complementary outputs provide both inverting and non-inverting buffer operation. A Strobe input is provided which, when at the high level, disables all data inputs and forces the $Y$ output to the low state and the W output to the high state. The Select input buffers incorporate internal overlap features to ensure that select input changes do not cause invalid output transients.

## Connection Diagram

TL/F/6203-1
Order Number DM54ALS151J, DM74ALS151M or DM74ALS151N
See NS Package Number J16A, M16A or N16A

## Features

- Advanced oxide-isolated, ion-implanted Schottky TTL process
■ Switching performance is guaranteed over full temperature and $V_{C C}$ supply range
- Pin and functional compatible with LS family counterpart
- Improved output transient handling capability

## DM54ALS153/DM74ALS153 Dual 1 of 4 Line Data Selector/Multiplexer

## General Description

This Data Selector/Multiplexer contains full on-chip decoding to select one-of-four data sources as a result of a unique two-bit binary code at the Select inputs. Each of the two Data Selector/Multiplexer circuits have their own separate Data and Strobe inputs and a non-inverting output buffer. The Select inputs A and B are common to both sections. The Strobe inputs, when at the high level, disable their associated data inputs and force the corresponding output to the low state. The Select input buffers incorporate internal overlap features to ensure that select input changes do not cause invalid output transients.

## Connection Diagram

Order Number DM54ALS153J, DM74ALS153M, DM74ALS153N or DM74ALS153SJ
See NS Package Number J16A, M16A, M16D or N16A

## Features

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Switching performance is guaranteed over full temperature and $V_{C C}$ supply range
- Pin and functional compatible with LS family counterpart
- Improved output transient handling capability

## Function Table

## Logic Diagram

## DM74ALS157/DM74ALS158 Quad 1 of 2 Line Data Selector/Multiplexer

## General Description

These data selectors/multiplexers contain inverters and drivers to supply full on-chip data selection to the four output gates. A separate strobe input is provided. A 4-bit word is selected from one of two sources and is routed to the four outputs. The ALS157 presents true data whereas the ALS158 presents inverted data to minimize propagation delay time.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with Schottky and low power Schottky TTL counterpart
- Improved AC performance over Schottky and low power Schottky counterparts
- Expand any data input point
- Multiplex dual data buses
- General four functions of two variables (one variable is common)

National Semiconductor

# DM54ALS/DM74ALS160B, 161B, 162B, 163B Synchronous Four-Bit Counter 

## General Description

These synchronous presettable counters feature an internal carry look ahead for application in high speed counting designs. The ALS160B and ALS162B are four-bit decade counters, while the ALS161B and ALS163B are four-bit binary counters. The ALS160B and ALS161B clear asynchronously, while the ALS162B and ALS163B clear synchronously. The carry output is decoded to prevent spikes during normal counting mode of operation. Synchronous operation is provided by having all flip-flops clocked simultaneously so that outputs change coincident with each other when so instructed by count enable inputs and internal gating. This mode of operation eliminates the output counting spikes which are normally associated with asynchronous (ripple clock) counters. A buffered clock input triggers the four flipflops on the rising (positive-going) edge of the clock input waveform.
These counters are fully programmable, that is, the outputs may be preset to either level. As presetting is synchronous, setting up a low level at the load input disables the counter and causes the outputs to agree with set up data after the next clock pulse regardless of the levels of enable input. Low to high transitions at the load input are perfectly acceptable regardless of the logic levels on the clock or enable inputs.
The ALS160B and ALS161B clear function is asynchronous. A low level at the clear input sets all four of the flip-flop outputs low regardless of the levels of clock, load or enable inputs. These two counters are provided with a clear on power-up feature. The ALS162B and ALS163B clear function is synchronous; and a low level at the clear input sets all four of the flip-flop outputs low after the next clock pulse, regardless of the levels of enable inputs. This synchronous clear allows the count length to be modified easily, as decoding the maximum count desired can be accomplished with one external NAND gate. The gate output is connected to the clear input to synchronously clear the counter to all low outputs. Low to high transitions at the clear input of the ALS162B and ALS163B are also permissible regardless of the levels of logic on the clock, enable or load inputs.
The carry look ahead circuitry provides for cascading counters for n bit synchronous application without additional gating. Instrumental in accomplishing this function are two count enable inputs ( P and T ) and a ripple carry output. Both count enable inputs must be high to count. The $T$ input is fed forward to enable the ripple carry output. The ripple carry output thus enabled will produce a high level output pulse with a duration approximately equal to the high level portion of QA output. This high level overflow ripple carry pulse can be used to enable successive cascaded stages. High to low level transitions at the enable P or T inputs of the ALS160B through ALS163B may occur regardless of the logic level on the clock.

The ALS160B through ALS163B feature a fully independent clock circuit. changes made to control inputs (enable P or T , or load) that will modify the operating mode will have no effect until clocking occurs. The function of the counter (whether enabled, disabled, loading or counting) will be dictated solely by the conditions meeting the stable set-up and hold times.

## Features

- Switching specifications at 50 pF

■ Switching specifications guaranteed over full temperature and $V_{C C}$ range

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin-for-pin compatible with Schottky and low power Schottky TTL counterpart
- Improved AC performance over Schottky and low power Schottky counterparts
- Synchronously programmable
- Internal look ahead for fast counting
- Carry output for n-bit cascading

■ Synchronous counting

- Load control line
- ESD inputs

| ${ }_{\text {tPHL }}$ | Propagation Delay Time High to Low Level Output | H | $\overline{\mathrm{Q}}_{\mathrm{H}}$ |  | 3 | 9 | 17 | 3 | 9 | 16 |  |

Note 1: All typical values are at $\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$.
Note 2: The output conditions have been chosen to produce a current that closely approximates one half of the true short-circuit output current, los.
Note 3: With the outputs open, CLK INH and CLK at 4.5 V , and a clock pulse applied to the $\mathrm{SH} / \overline{\mathrm{LD}}$ input, ICC is measured first with the parallel inputs at 4.5 V , then with the parallel inputs grounded.
Note 4: See Section 1 for test waveforms and output load.

## Timing Diagram

DM54ALS166/DM74ALS166 8-Bit Parallel Load Shift Registers

## ADVANCE INFORMATION

## General Description

These parallel-in or serial-in, serial-out shift registers feature gated clock inputs and an overriding clear input. All inputs are buffered to lower the drive requirements to one normalized load, and input clamping diodes minimize switching transients to simplify system design. The load mode is established by the shift/load input. When high, this input enables the serial data input and couples the eight flip-flops for serial shifting with each clock pulse. When low, the parallel (broadside) data inputs are enabled and synchronous loading occurs on the next clock pulse. During parallel loading, serial data flow is inhibited. Clocking is accomplished on the low-to-high level edge of the clock pulse through a 2 -input NOR gate, permitting one input to be used as a clock en-
able or clock inhibit function. Holding either of the clock inputs high inhibits clocking; holding either low enables the other clock input. This allows the system clock to be freerunning, and the register can be stopped on command with the other clock input. The clock inhibit input should be changed to the high level only while the clock input is high. A buffered, direct clear input overrides all other inputs, including the clock, and sets all flip-flops to zero.

## Features

■ Synchronous load

- Direct overriding clear
- Parallel-to-serial conversion

## DM74ALS168B, DM54ALS/DM74ALS169B Synchronous Four-Bit Up/Down Counters

## General Description

These synchronous presettable counters feature an internal carry look ahead for cascading in high speed counting applications. The ALS168B is a four-bit decade up/down counter and the ALS169B is a four-bit binary up/down counter. The carry output is decoded to prevent spikes during normal mode of counting operation. Synchronous operation is provided so that outputs change coincident with each other when so instructed by count enable inputs and internal gating. This mode of operation eliminates the output counting spikes which are normally associated with asynchronous (ripple clock) counters. A buffered clock input triggers the four flip-flops on the rising (positive going) edge of clock input waveform.
These counters are fully programmable; that is, the outputs may each be preset either high or low. The load input circuitry allows loading with carry-enable output of cascaded counters. As loading is synchronous, setting up a low level at the load input disables the counter and causes the outputs to agree with the data inputs after the next clock pulse. The carry look-ahead circuitry permits cascading counters for $n$-bit synchronous applications without additional gating. Both count enable inputs ( $\overline{\mathrm{P}}$ and $\overline{\mathrm{T}}$ ) must be low to count. The direction of the count is determined by the level of the up/down input. When the input is high, the counter counts up; when low, it counts down. Input T is fed forward to enable the carry outputs. The carry output thus enabled will produce a low level output pulse with a duration approximately equal to the high portion of the $Q_{A}$ output when counting up, and approximately equal to the low portion of the $Q_{A}$ when counting down. This low level overflow carry
pulse can be used to enable successively cascaded stages. Transitions at the enable $\overline{\mathrm{P}}$ or $\overline{\mathrm{T}}$ inputs are allowed regardless of the level of the clock input.
The control functions for these counters are fully synchronous. Changes at control inputs (enable $\overline{\mathrm{P}}$, enable $\overline{\mathrm{T}}$, load, up/down) which modify the operating mode have no effect until clocking occurs. The function of the counter (whether enabled, disabled, loading or counting) will be dictated solely by the conditions meeting the stable setup and hold times.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin-for-pin compatible with Schottky and low power Schottky TTL counterpart
- Improved AC performance over Schottky and low power Schottky counterparts
- Synchronously programmable
- Internal look ahead for fast counting
- Carry output for n-bit cascading
- Synchronous counting
- ESD inputs

| ${ }_{\text {tPLH }}$ | Propagation Delay Time Low to High Level Output |  | $U / \bar{D}$ (Note 2) | $\overline{\text { Ripple }}$ Carry | 5 | 21 | 5 | 19 | ns |
| $\mathrm{t}_{\mathrm{PHL}}$ | Propagation Delay Time High to Low Level Output |  | $\begin{gathered} \hline U / \bar{D} \\ \text { (Note 2) } \end{gathered}$ | $\overline{\text { Ripple }}$ Carry | 5 | 22 | 5 | 19 | ns |

Note 1: See Section 1 for test waveforms and output load.
Note 2: Propagation delay time from up/down to ripple carry must be measured with the counter at either a minimum or a maximum count. As the logic level of the up/down input is changed, the ripple carry output will follow. If the count is minimum ( 0 ), the ripple carry output transition will be in phase. If the count is maximum ( 9 for ALS168B or 15 for ALS169B), the ripple carry output will be out of phase.

## DM54ALS174/DM54ALS175/DM74ALS174/DM74ALS175 Hex/Quad D Flip-Flop with Clear

## General Description

These positive-edge-triggered flip-flops utilize TTL circuitry to implement D-type flip-flop logic. Both have an asynchronous clear input, and the quad (175) version features complementary outputs from each flip-flop.
Information at the D inputs meeting the setup time requirements is transferred to the Q outputs on the positive-going edge of the clock pulse. Clock triggering occurs at a particular voltage level and is not directly related to the transition time of the positive-going pulse. When the clock input is at either the high or low level, the D input signal has no effect at the output.

## Features

■ Advanced oxide-isolated ion-implanted Schottky TTL process
■ Pin and functional compatible with LS family counterpart

- Typical clock frequency maximum is 80 MHz

■ Switching performance guaranteed over full temperature and $V_{C C}$ supply range

- 54ALS174 contains six flip-flops with separate $D$ inputs and Q outputs
- 54ALS175 contains four flip-flops with separate D inputs and both Q and $\overline{\mathrm{Q}}$ outputs

## DM54ALS240A/DM74ALS240A/DM74ALS241A Octal TRI-STATE ${ }^{\circledR}$ Bus Driver

## General Description

These octal TRI-STATE bus drivers are designed to provide the designer with flexibility in implementing a bus interface with memory, microprocessor, or communication systems. The output TRI-STATE gating control is organized into two separate groups of four buffers. The ALS240A control inputs symmetrically enable the respective outputs when set logic low, while the ALS241A has complementary enable gating. The TRI-STATE circuitry contains a feature that maintains the buffer outputs in TRI-STATE (high impedance state) during power supply ramp-up or ramp-down. This eliminates bus glitching problems that arise during power-up and power-down.

## Features

- Advanced low power oxide-isolated ion-implanted Schottky TTL process
■ Functional and pin compatible with the DM54/74LS counterpart
- Improved switching performance with less power dissipation compared with the DM54/74LS counterpart
- Switching response specified into $500 \Omega$ and 50 pF load
n Switching response specifications guaranteed over full temperature and $V_{C C}$ supply range
- PNP input design reduces input loading
- Low level drive current:
$54 \mathrm{ALS}=12 \mathrm{~mA}, 74 \mathrm{ALS}=24 \mathrm{~mA}$

## DM74ALS242C/DM74ALS243A

## Quad TRI-STATE® Bidirectional Bus Driver

## General Description

These octal TRI-STATE ${ }^{\oplus}$ bus drivers are designed to provide the designer with flexibility in implementing a bus interface with memory, microprocessor, or communication systems. The ALS242C has inverting buffers, while the ALS243A has non-inverting buffers. The direction enable gating is configured with separate control over either buffer direction and the two control buffers are complementary. Connecting these control inputs to one common line implements single line direction control, while individual control can put both buffer directions into TRI-STATE simultaneously (disabled state) or put both buffer directions into the active state (data latch state). The TRI-STATE circuitry contains a feature that maintains the buffer outputs in TRISTATE (high impedance state) during power supply rampup or ramp-down. This eliminates bus glitching problems that arise during power-up and power-down.

## Features

■ Advanced low power oxide-isolated ion-implanted Schottky TTL process

- Functional and pin compatible with the 74LS counterpart
- Improved switching performance with less power dissipation compared with the 74LS counterpart
■ Switching response specified into $500 \Omega$ and 50 pF load
■ Switching response specifications guaranteed over full temperature and $V_{C C}$ supply range
- PNP input design reduces input loading
- Low level drive current: 74ALS $=24 \mathrm{~mA}$

## Connection Diagram

Order Number DM74ALS242CM, DM74ALS242CN, DM74ALS243AM or DM74ALS243AN See NS Package Number M14A or N14A

## Function Table

| Inputs |  | 'ALS242C | 'ALS243A |
| :---: | :---: | :---: | :---: |

## DM54ALS244A/DM74ALS244A Octal TRI-STATE ${ }^{\circledR}$ Bus Driver

## General Description

This octal TRI-STATE bus driver is designed to provide the designer with flexibility in implementing a bus interface with memory, microprocessor, or communication systems. The output TRI-STATE gating control is organized into two separate groups of four buffers, and both control inputs enable the respective outputs when set logic low. The TRI-STATE circuitry contains a feature that maintains the buffer outputs in TRI-STATE (high impedance state) during power supply ramp-up or ramp-down. This eliminates bus glitching problems that arise during power-up and power-down.

## Features

- Advanced low power oxide-isolated ion-implanted Schottky TTL process
■ Functional and pin compatible with the DM54/74LS counterpart
- Improved switching performance with less power dissipation compared with the DM54/74LS counterpart
- Switching response specified into $500 \Omega$ and 50 pF load
- Switching response specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ supply range
■ PNP input design reduces input loading
- Low level drive current:
$54 \mathrm{ALS}=12 \mathrm{~mA}, 74 \mathrm{ALS}=24 \mathrm{~mA}$

## Connection Diagram

## Logic Diagram

## DM54ALS245A/DM74ALS245A Octal TRI-STATE ${ }^{\circledR}$ Bus Transceiver

## General Description

This advanced low power Schottky device contains 8 pairs of TRI-STATE logic elements configured as octal bus transceivers. These circuits are designed for use in memory, microprocessor systems and in asynchronous bidirectional data buses. Two way communication between buses is controlled by the (DIR) input. Data transmits either from the A bus to the $B$ bus or from the $B$ bus to the $A$ bus. Both the driver and receiver outputs can be disabled via the ( $\bar{G}$ ) enable input which causes outputs to enter the high impedance mode so that the buses are effectively isolated.

## Features

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Non-inverting logic output
- Glitch free bus during power up and down
- TRI-STATE outputs independently controlled on A and B buses
- Low output impedance to drive terminated transmission lines to $133 \Omega$
- Switching response specified into $500 \Omega / 50 \mathrm{pF}$
- Specified to interface with CMOS at $\mathrm{V}_{\mathrm{OH}}=\mathrm{V}_{\mathrm{CC}}-2 \mathrm{~V}$
- PNP inputs to reduce input loading
- Switching specifications guaranteed over full temperature and $V_{C C}$ range

## DM54ALS251/DM74ALS251 TRI-STATE® 1 of 8 Line Data Selector/Multiplexer

## General Description

This Data Selector/Multiplexer contains full on-chip decoding to select one-of-eight data sources as a result of a unique three-bit binary code at the Select inputs. Two complementary outputs provide both inverting and non-inverting buffer operation. An Output Control input is provided which, when at the high level, places both outputs in the high impedance Off state. In order to prevent bus access conflicts, output disable times are shorter than output enable times. The Select input buffers incorporate internal overlap features to ensure that select input changes do not cause invalid output transients.

## Features

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Switching performance is guaranteed over full temperature and $V_{C C}$ supply range
- Pin and functional compatible with LS family counterpart
- Improved output transient handling capability

■ Output control circuitry incorporates power-up TRI-STATE feature

## DM54ALS253/DM74ALS253 TRI-STATE® Dual 1 of 4 Line Data Selector/Multiplexer

## General Description

This Data Selector/Multiplexer contains full on-chip decoding to select one-of-four data sources as a result of a unique two-bit binary code at the Select Inputs. Each of the two Data Selector/Multiplexer circuits have their own separate Data and Output Control inputs and a non-inverting TRISTATE output buffer. The Output Control inputs, when at the high level, place the corresponding output in the high impedance Off state. In order to prevent bus access conflicts, output disable times are shorter than output enable times. The Select input buffers incorporate internal overlap features to ensure that select input changes do not cause invalid output transients.

## Connection Diagram

## Features

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Switching performance is guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ supply range
- Pin and functional compatible with LS family counterpart
■ Improved output transient handling capability
- Output control circuitry incorporates power-up TRISTATE feature

## Function Table

| Select <br> Inputs | Data Inputs |  |  |  | Output <br> Control | Output |  |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| B | A | Co | C1 | C2 | C3 | G | Y |
| X | X | X | X | X | X | H | Z |
| L | L | L | X | X | X | L | L |
| L | L | H | X | X | X | L | H |
| L | H | X | L | X | X | L | L |
| L | H | X | H | X | X | L | H |
| H | L | X | X | L | X | L | L |
| H | L | X | X | H | X | L | H |
| H | H | X | X | X | L | L | L |
| H | H | X | X | X | H | L | H |

Address inputs $A$ and $B$ are common to both sections
$H=$ High Level, $L=$ Low Level, $X=$ Don't Care, $\mathbf{Z}=$ High Impedance

## Absolute Maximum Ratings

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for avallability and specificatlons.

## DM74ALS257/DM74ALS258 TRI-STATE® <br> Quad 1-of-2-Line Data Selector/Multiplexer

## General Description

These data selectors/multiplexers contain inverters and drivers to supply full on-chip data selection to the four TRISTATE outputs that can interface directly with data lines of bus-organized systems. A 4-bit word selected from one of two sources is routed to the four outputs. The ALS257 presents true data whereas the ALS258 presents inverted data to minimize propagation delay time.
This TRI-STATE output feature means that $n$-bit (paralleled) data selectors with up to 258 sources can be implemented for data buses. It also permits the use of standard TTL registers for data retention throughout the system.

## Features

■ Switching specifications at 50 pF

- Switching specifications guaranteed over full temperature and $V_{\mathrm{CC}}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with Schottky and low power Schottky TTL counterpart
- Improved AC performance over Schottky and low power Schottky counterparts
- TRI-STATE buffer-type outputs drive bus lines directly
- Expand any data input point
- Multiplex dual data buses
- General four functions of two variables (one variable is common)
- Source programmable counters

## Connection Diagram

## DM54ALS273/DM74ALS273 Octal D-Type Edge-Triggered Flip-Flop with Clear

## General Description

These monolithic, positive-edge-triggered flip-flops utilize TTL circuitry to implement D-type flip-flop logic with a direct clear input.
Information at the D inputs meeting the setup requirements is transferred to the Q outputs on the positive-going edge of the clock pulse. Clock triggering occurs at a particular voltage level and is not directly related to the transition time of the positive-going pulse. When the clock input is at either the high or low level, the $D$ input signal has no effect at the output.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Buffer-type outputs and improved AC offer significant advantage over 'LS273.
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin-for-pin compatible with 'LS273.

## Connection Diagram

## DM74ALS299

## TRI-STATE ${ }^{\circledR}$ 8-Bit Universal Shift/Storage Register

## Description

This eight-bit universal register features multiplexed inputs/ outputs to achieve full eight bit data handling in a single 20pin package. Two function-select inputs and two outputcontrol inputs can be used to choose the modes of operation listed in the function table.
Synchronous parallel loading is accomplished by taking both function-select lines, S0 and S1, high. This places the TRI-STATE outputs in a high-impedance state, which permits data that is applied on the input/output lines to be clocked into the register. Reading out of the register can be accomplished while the outputs are enabled in any mode. A direct overriding input is provided to clear the register whether the outputs are enabled or off.

## Features

- Multiplexed inputs/outputs provide improved bit density
- Four modes of operation:

Hold (Store) Shift Left
Shift Right Load Data

- TRI-STATE outputs drive bus lines directly
- Can be cascaded for N -bit word lengths
- Operates with outputs enabled or at high Z

## Connection Diagram

## Dual-In-Line Package

## DM74ALS352

## Dual 1 of 4 Line Data Selector/Multiplexer

## General Description

This Data Selector/Multiplexer contains full on-chip decoding to select one-of-four data sources as a result of a unique two-bit binary code at the Select inputs. Each of the two Data Selector/Multiplexer circuits have their own separate Data and Strobe inputs and an inverting output buffer. The Strobe inputs, when at the high level, disable their associated data inputs and force the corresponding output to the high state. The Select input buffers incorporate internal overlap features to ensure that select input changes do not cause invalid output transients.

## Features

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Switching performance is guaranteed over full temperature and $V_{C C}$ supply range
- Pin and functional compatible with the LS family counterpart
- Improved output transient handling capability

TRI-STATE ${ }^{\circledR}$ Dual 1 of 4 Line Data Selector/Multiplexer

## General Description

This Data Selector/Multiplexer contains full on-chip decoding to select one-of-four data sources as a result of a unique two-bit binary code at the Select inputs. Each of the two Data Selector/Multiplexer circuits have their own separate Data and Output Control inputs and an inverting TRI-STATE output buffer. The Output Control inputs, when at the high level, place the corresponding output in the high impedance Off state. In order to prevent bus access conflicts, output disable times are shorter than output enable times. The Select input buffers incorporate internal overlap features to ensure that select input changes do not cause invalid output transients.

## Features

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Switching performance is guaranteed over full temperature and $V_{C C}$ supply range
- Pin and functional compatible with LS family counterpart
- Improved output transient handling capability
- Output control circuitry incorporates power-up TRISTATE feature

## DM54ALS373/DM74ALS373

Octal D-Type TRI-STATE® Transparent Latch

## General Description

These 8-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight latches of the ALS373 are transparent D-type latches. While the enable $(G)$ is high the $Q$ outputs will follow the data ( $D$ ) inputs. When the enable is taken low the output will be latched at the level of the data that was set up.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high-impedance state. In the high-impedance
state the outputs neither load nor drive the bus lines significantly.
The output control does not affect the internal operation of the latches. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with LS TTL counterpart
- Improved AC performance over LS373 at approximately half the power
- TRI-STATE buffer-type outputs drive bus lines directly

## DM54ALS374/DM74ALS374 Octal TRI-STATE® D-Type Edge-Triggered Flip-Flop

## General Description

These 8 -bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, 1/O ports, bidirectional bus drivers, and working registers.
The eight flip-flops of the ALS374 are edge-triggered D-type flip-flops. On the positive transition of the clock, the Q outputs will be set to the logic states that were set up at the D inputs.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.

The output control does not affect the internal operation of the flip-flops. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
■ Functionally and pin-for-pin compatible with LS TTL counterpart
- Improved AC performance over LS374 at approximately half the power
- TRI-STATE buffer-type outputs drive bus lines directly

## DM74ALS465A/466A/467A/468A <br> Octal TRI-STATE ${ }^{\circledR}$ Bidirectional Bus Driver

## General Description

These octal TRI-STATE bus drivers are designed to provide the designer with flexibility in implementing a bus interface with memory, microprocessor, or communication systems. The output TRI-STATE gating control is organized into two separate groups of four buffers on the ALS467A and ALS468A, and one common gating control for all eight buffers on the ALS465A and ALS466A. All control inputs are active low enabling. The buffers on the ALS465A and ALS467A are non-inverting and the buffers on the ALS466A and ALS468A are inverting. The TRI-STATE circuitry contains a feature that maintains the buffer outputs in TRI-STATE (high impedance state) during power supply ramp-up or ramp-down. This eliminates bus glitching problems that arise during power-up and power-down.

## Features

E Advanced low power oxide-isolated ion-implanted Schottky TTL process

- Functional and pin compatible with the DM54/74LS counterpart and the DM71/81LS95, 96, 97, 98
- Improved switching performance with less power dissipation compared with the DM54/74LS counterpart
- Switching response specified into $500 \Omega$ and 50 pF load
- Switching response specifications guaranteed over full temperature and $V_{C C}$ supply range
- PNP input design reduces input loading

## National Semiconductor DM54/74ALS518/519/520/521/522 8-Bit Comparator

## General Description

These comparators perform an "equal to" comparison of two eight-bit words with provision for expansion or external enabling. The matching of the two 8 -bit input plus a logic LOW on the EN input produces the output $A=B$ on the ALS518 and 519 and the output $\overline{\mathrm{A}=\mathrm{B}}$ on the ALS520, 521 and 522. The ALS520 and 521 have totem pole outputs, while the ALS518, 519 and 522 have open collector outputs for wire AND cascading. Additionally, the ALS518, 520 and 522 are provided with $B$ input pull up termination resistors for analog or switch data.

## DM74ALS533

Octal D-Type Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These 8-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight inverting latches of the ALS533 are transparent D-type latches. While the enable $(G)$ is high the $Q$ outputs will follow the complement of the data ( $D$ ) inputs. When the enable is taken low the output will be latched at the complement of the level of the data that was set up.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic
levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.
The output control does not affect the internal operation of the latches. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

■ Switching specifications at 50 pF

- Switching specifications guaranteed over full temperature and $V_{\mathrm{CC}}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- TRI-STATE buffer-type outputs drive bus lines directly

## DM74ALS534 Octal D-Type Edge-Triggered Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These 8-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight flip-flops of the ALS534 are edge-triggered inverting D-type flip-flops. On the positive transition of the clock, the Q outputs will be set to the complement of the logic states that were set up at the D inputs.

A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.
The output control does not affect the internal operation of the flip-flops. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process

## DM74ALS540A Octal Inverting Buffer and Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

This octal buffer and line driver is designed to have the performance of the 'ALS240 series and, at the same time, offer a pinout with inputs and outputs on opposite sides of the package. This arrangement greatly enhances printed circuit board layout. The TRI-STATE control gate is a 2 -input NOR such that if either $\overline{\mathrm{G}} 1$ or $\overline{\mathrm{G}} 2$ is high, all eight outputs are in the high impedance state.

## Features

■ Advanced oxide-isolated, ion-implanted Schottky TTL process

- Switching performance is guaranteed over full temperature and $V_{C C}$ supply range
- Data flow-thru pinout (All inputs on opposite side from outputs)
- P-N-P inputs reduce DC loading

Connection Diagram

## DM74ALS541

## Octal Buffer and Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

This octal buffer and line driver is designed to have the performance of the 'ALS240 series and, at the same time, offer a pinout with inputs and outputs on opposite sides of the package. This arrangement greatly enhances circuit board layout. The TRI-STATE control gate is a 2 -input NOR such that if either G1 or G2 is high, all eight outputs are in the high impedance state.

Features
■ Advanced oxide-isolated ion-implanted Schottky TTL process

- Switching performance is guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ supply range
- Data flow-thru pinout (all inputs on opposite side from outputs)
- P-N-P Inputs reduce DC loading

## Connection Diagram

Function Table

| Input |  |  | Output <br> Y |
| :---: | :---: | :---: | :---: |
| $\overline{\mathbf{G} 1}$ | $\overline{\mathbf{G} 2}$ | $\mathbf{A}$ |  |

## DM74ALS563A Octal D-Type

Transparent Latch with TRI-STATE ${ }^{\circledR}$ Output

## General Description

These 8-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight inverting latches of the ALS563A are transparent D-type latches. While the enable ( $G$ ) is high the Q outputs will follow the data (D) inputs. When the enable is taken low the output will be latched at the complement of the level of the data that was set up.

A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.
The output control does not affect the internal operation of the latches. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

- Switching specifications at 50 pF

■ Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process

- TRI-STATE buffer-type outputs drive bus lines directly

## Connection Diagram

Function Table

## DM74ALS564A Octal D-Type <br> Edge-Triggered Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These 8 -bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight flip-flops of the ALS564A are edge-triggered inverting D-type flip-flops. On the positive transition of the clock, the $\bar{Q}$ outputs will be set to the complement of the logic states that were set up at the $D$ inputs.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic
levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.
The output control does not affect the internal operation of the flip-flops. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range

## DM74ALS573B Octal D-Type Transparent <br> Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These 8-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight latches of the ALS573B are transparent D-type latches. While the enable ( G ) is high the Q outputs will follow the data ( $D$ ) inputs. When the enable is taken low the output will be latched at the level of the data that was set up.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high-impedance state. In the high-impedance
state the outputs neither load nor drive the bus lines significantly.
The output control does not affect the internal operation of the latches. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally equivalent with LS373
- Improved AC performance over LS373 at approximately half the power
- TRI-STATE buffer-type outputs drive bus lines directly

## Connection Diagram

## DM74ALS580A Octal D-Type Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These 8-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight inverting latches of the ALS580A are transparent D-type latches. While the enable (G) is high the Q outputs will follow the complement of the data (D) inputs. When the enable is taken low the output will be latched at the complement of the level of the data that was set up.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic
levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.
The output control does not affect the internal operation of the latches. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

■ Switching specifications at 50 pF

- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- TRI-STATE buffer-type outputs drive bus lines directly

## Connection Diagram

Dual-In-Line Package

Order Number DM74ALS580AWM or DM74ALS580AN
See NS Package Number M20B or N20A

## Function Table

| Output <br> Control | Enable <br> G | D | Output <br> $\overline{\mathbf{Q}}$ |

## DM74ALS620A

## Octal TRI-STATE ${ }^{\circledR}$ Bus Transceiver

## General Description

This advanced low power Schottky device contains 8 pairs of TRI-STATE logic elements configured as an octal bus transceiver. It is designed for use in memory, microprocessor systems and in asynchronous bidirectional data buses. Data transmission from the $A$ bus to the $B$ bus or from the $B$ bus to the $A$ bus is selectively controlled by (GBA and GAB) the enable inputs. These inputs are also used to disable the devices so that the buses are effectively isolated.
The dual-enable configuration gives the ALS620A the capability to store data by simultaneous enabling of ḠBA and GAB. Each output reinforces its input in this transceiver configuration. Thus, when both control inputs are enabled and all other data sources to the two sets of bus lines are at high impedance, both sets of bus lines will remain at their last logic states.

## Features

■ Advanced oxide-isolated, ion-implanted Schottky TTL process

- TRI-STATE outputs on A and B buses
- Local bus-latch capability
- Switching specifications into $500 \Omega / 50 \mathrm{pF}$
- Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range
- Low output impedance to drive terminated transmission lines to $133 \Omega$

## DM74ALS640A Inverting Octal Bus Transceiver

## General Description

This inverting octal bus transceiver is designed for asynchronous two-way communication between data busses. This device transmits data from the A bus to the B bus or from the $B$ bus to the $A$ bus depending upon the level at the direction control (DIR) input. The enable input (G) can be used to disable the device so the busses are effectively isolated.

## Features

- Advanced Oxide-isolated lon-implanted Schottky TTL process
- Switching performance is guaranteed over full temperature and $V_{C C}$ supply range
- Switching performance specified at 50 pF
- PNP input design reduces input loading

National Semiconductor

## DM74ALS645A Octal Bus Transceivers

## General Description

These octal bus transceivers are designed for asynchronous two-way communication between data busses. These devices transmit data from the A bus to the B bus or from the $B$ bus to the $A$ bus depending upon the level at the direction control (DIR) input. The enable input (G) can be used to disable the device so the busses are effectively isolated.

## Features

- Advanced Oxide-isolated Ion-implanted Schottky TTL process
- Switching performance is guaranteed over full temperature and $V_{C C}$ supply range
- Switching performance specified at 50 pF
- PNP input design reduces input loading

## Connection and Logic Diagrams

## DM74ALS646

## Octal TRI-STATE® Bus Transceiver and Register

## General Description

This device incorporates an octal bus transceiver and an octal D-type register configured to enable multiplexed transmission of data from bus to bus or internal register to bus.
This bus transceiver features totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic level drive provides this device with the capability of being connected directly to and driving the bus lines in a bus-organized system without the need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The registers in the ALS646 are edge-triggered D-type flipflops. On the positive transition of the clock (CAB or CBA), the input bus data is stored into the appropriate register. The CAB input controls the transfer of data into the A register and the CBA input controls the B register.
The SAB and SBA control pins are provided to select whether real-time data or stored data is transferred. A low input level selects real-time data, and a high level selects stored data. The select controls have a "make before
break" contiguration to eliminate a glitch which would normally occur in a typical multiplexer during the transition between store and real-time data.
The enable $\bar{G}$ and direction control pins provide four modes of operation: real-time data transfer from bus $A$ to $B$, realtime data transfer from bus B to A, real-time bus A and/or B data transfer to internal storage, or internally stored data transfer to bus A or B.
When the enable $\bar{G}$ pin is low, the direction pin selects which bus receives data. When the enable $G$ pin is high, both buses become disabled yet their input function is still enabled.

## Features

(1) Switching specifications at 50 pF

- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- TRI-STATE buffer outputs drive bus lines directly
- Multiplexed real-time and stored data
- Independent registers for $A$ and $B$ buses

## Octal TRI-STATE® ${ }^{\circledR}$ Inverting Bus Transceiver

## General Description

This device incorporates an octal bus transceiver and an octal D-type register configured to enable multiplexed transmission of data from bus to bus or internal register to bus.
This bus transceiver features totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic level drive provides this device with the capability of being connected directly to and driving the bus lines in a bus-organized system without the need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The registers in the ALS648 are edge-triggered D-type flipflops. On the positive transition of the clock (CAB or CBA), the input bus data is stored into the appropriate register. The CAB input controls the transfer of data into the A register and the CBA input controls the B register.
The SAB and SBA control pins are provided to select whether real-time data or stored data is transferred. A low input level selects real-time data, and a high level selects stored data. The select controls have a "make before break" configuration to eliminate a glitch which would nor-
mally occur in a typical multiplexer during the transition between stored and real-time data.
The enable $\overline{\mathcal{G}}$ and direction control pins provide four modes of operation: real-time data transfer from bus $A$ to $B$, realtime data transfer from bus B to A, real-time bus A and/or B data transfer to internal storage, or internally stored data transfer to bus A or B.
When the enable $\bar{G}$ pin is low, the direction pin selects which bus receives data. When the enable $G$ pin is high, both buses became disabled yet their input function is still enabled.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- TRI-STATE buffer outputs drive bus lines directly
- Multiplexed real-time and stored data
- Independent registers for $A$ and $B$ buses

Octal TRI-STATE® Bus Transceiver and Register

## General Description

This device incorporates an octal transceiver and an octal D-type register configured to enable transmission of data from bus to bus or internal register to bus.
This bus transceiver features totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high level logic drive provide this device with the capability of being connected directly to and driving the bus lines in a bus organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The registers in the AS651 are edge-triggered D-type flipflops. On the positive transition of the clock (CAB or CBA), the input data is stored into the appropriate register. The $C A B$ input controls the transfer of data into the $A$ register and the CBA input controls the B register.
The SAB and SBA control pins are provided to select whether real-time data or stored data is transferred. A low input level selects real-time data and a high level selects
stored data. The select controls have a "make before break" configuration to eliminate a glitch which would normally occur in a typical multiplexer during the transition between stored and real-time data.
The enable (GAB and GBA) control pins provide four modes of operation: real-time data transfer from bus $A$ to $B$, realtime data transfer from bus $B$ to $A$, real-time bus $A$ and/or $B$ data transfer to internal storage, or internal stored data transfer to bus A and/or B.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- TRI-STATE buffer-type outputs drive bus lines directly
- Independent registers and enables for $A$ and $B$ buses
- Multiplexed real-time and stored data

| H | H | $\uparrow$ | $\uparrow$ | X(Note 4) | X | Input | Output | Store A in both Registers |
| L | L | $\uparrow$ | $\uparrow$ | X | X(Note 4) | Output | Input | Store B in both Registers |

Note 3: The data output functions may be enabled or disabled by various signals at the $\bar{G}$ and DIR inputs. Data input functions are always enabled, i.e., data at the bus pins will be stored on every low-to-high transition on the clock inputs.
Note 4: Select control = L; clocks can occur simultaneously
Select control $=\mathrm{H}$; clocks must be staggered in order to load both registers.
$H=$ High Logic Level, $L=$ Low Logic Level, $X=$ Don't Care (Either Low or High Logic Levels, including transitions), $H / L=$ Either Low or High Logic Level excluding transitions, $\uparrow=$ Positive-going edge of pulse.

## Logic Diagram

## DM74ALS689 8-Bit Comparator

## General Description

This comparator performs an "equal to" comparison of two eight-bit words with provision for expansion or external enabling. The matching of the two 8 -bit inputs plus a logic LOW on the EN input produces the output $A=B$. The ALS689 has an open collector output for wire AND cascading.

## Features

- Switching specifications at 50 pF

■ Switching specifications guaranteed over full temperature and $V_{C C}$ range

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with LS family TTL counterpart
- Improved output transient handling capability

## Connection Diagram

## Dual-In-Line Package

Order Number DM74ALS689WM or DM74ALS689N
See NS Package Number M20B or N20A

## Function Table

| Inputs |  | Output |
| :---: | :---: | :---: |
| $\overline{E N}$ | Data | $\overline{A=B}$ |
| $L$ | $A=B$ | $L$ |
| $L$ | $A \neq B$ | $H$ |
| $H$ | $X$ | $H$ |

$H=$ High Level, $L=$ Low Level, $X=$ Don't Care

Absolute Maximum Ratings

| Supply Voltage | 7 V |
| :--- | ---: |
| Input Voltage | 7 V |
| Off State Output Voltage | 7 V |
| Operating Free Air Temperature Range |  |
| DM74ALS | $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Typical $\theta_{J A}$ |  |
| N Package | $62.0^{\circ} \mathrm{C} / \mathrm{W}$ |
| M Package | $82.0^{\circ} \mathrm{C} / \mathrm{W}$ |

Note: The "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. The device should not be operated at these limits. The parametric values defined in the "Electrical Characteristics" table are not guaranteed at the absolute maximum ratings. The "Recommended Operating Conditions" table will define the conditions for actual device operation.

Recommended Operating Conditions

## DM74ALS811 Quad 2-Input Exclusive-NOR <br> Gate with Open-Collector Outputs

## General Description

This device contains four independent gates, each of which performs the logic exclusive-NOR function. The open-collector outputs require external pull-up resistors for proper logical operation.

## Pull-Up Resistor Equations

$$
\begin{aligned}
& \mathrm{R}_{\mathrm{MAX}}=\frac{\mathrm{V}_{\mathrm{CC}}(\mathrm{Min})-\mathrm{V}_{\mathrm{OH}}}{\mathrm{~N}_{1}\left(\mathrm{IOH}^{(O H}\right)+\mathrm{N}_{2}\left(\mathrm{I}_{\mathrm{H}}\right)} \\
& \mathrm{R}_{\mathrm{MIN}}=\frac{\mathrm{V}_{\mathrm{CC}}(\mathrm{Max})-\mathrm{V}_{\mathrm{OL}}}{\mathrm{I}_{\mathrm{OL}}-\mathrm{N}_{3}\left(\mathrm{IIL}^{2}\right.}
\end{aligned}
$$

Where: $\quad N_{1}\left(I_{\mathrm{OH}}\right)=$ total maximum output high current for all outputs tied to pull-up resistor
$\mathrm{N}_{2}\left(\mathrm{l}_{1 \mathrm{H}}\right)=$ total maximum input high current for all inputs tied to pull-up resistor
$N_{3}\left(l_{1}\right)=$ total maximum input low current for all inputs tied to pull-up resistor

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with Schottky and low power Schottky TTL counterpart
- Improved AC performance over Schottky and low power Schottky counterparts

Absolute Maximum Ratings

## DM74ALS873B <br> Dual 4-Bit D-Type Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

This dual 4-bit register features totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight latches of the ALS873B are transparent D-type latches. While the enable $(G)$ is high the $Q$ outputs will follow the data ( D ) inputs. When the enable is taken low the output will be latched at the level of the data that was set up.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic
levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.
The output control does not affect the internal operation of the latches. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- TRI-STATE buffer-type outputs drive bus lines directly
- Space saving 300 mil wide package

## DM74ALS874B Dual 4-Bit D-Type Edge-Triggered Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These dual 4-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight flip-flops of the ALS874B are edge-triggered D-type flip-flops. On the positive transition of the clock, the Q outputs will be set to the logic states that were set up at the $D$ inputs.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.

The output control does not affect the internal operation of the flip-flops. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

- Switching specifications at 50 pF

■ Switching specifications guaranteed over full temperature and $V_{C C}$ range

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- TRI-STATE buffer-type outputs drive bus lines directly
- Space saving 300 mil wide package
- Asynchronous clear

## DM74ALS880A <br> Dual 4-Bit D-Type Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These dual 4-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight inverting latches of the ALS880A are transparent D-type latches. While the enable ( $G$ ) is high the $\bar{Q}$ outputs will follow the complement of the data ( $D$ ) inputs. When the enable is taken low the output will be latched at the complement of the level of the data that was set up.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic
levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.
The output control does not affect the internal operation of the latches. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

## DM74ALS1000A

## Quadruple 2-Input NAND Buffer

## General Description

These devices contain four independent 2 -input buffer/drivers, each of which performs the logic NAND function. The 'ALS1000A is a buffer/driver version of the 'ALSOOA.

## Features

- Switching specifications at 50 pF

■ Switching specifications guaranteed over full temperature and $V_{C C}$ range

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Improved line receiving characteristics

## Connection Diagram

Order Number DM74ALS1000AM or DM74ALST000AN See NS Package Number M14A or N14A

## Function Table

$$
\mathbf{Y}=\overline{\mathbf{A B}}
$$

| Inputs |  | Output |
| :---: | :---: | :---: |
| A | B | Y |
| L | L | H |
| L | H | H |
| H | L | H |
| H | H | L |

$H=$ High Logic Level
L = Low Logic Level

## Absolute Maximum Ratings

| Supply Voltage | 7 V |
| :--- | ---: |
| Input Voitage | 7 V |
| Operating Free Air Temperature Range |  |
| DM74ALS | $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Typical $\theta$ JA |  |
| N Package | $83.0^{\circ} \mathrm{C} / \mathrm{W}$ |
| M Package | $114.0^{\circ} \mathrm{C} / \mathrm{W}$ |

Note: The "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. The device should not be operated at these limits. The parametric values defined in the "Electrical Characteristics" table are not guaranteed at the absolute maximum ratings. The "Recommended Operating Conditions" table will define the conditions for actual device operation.

## Recommended Operating Conditions

## DM74ALS1003A Quadruple 2-Input NAND Buffer with Open-Collector Outputs

## General Description

This device contains four independent 2 -input buffers, each of which performs the logic NAND function. The outputs require an external pull-up resistor for proper logical operation. The 'ALS1003A is a buffer version of the 'ALS03A.

## Pull-Up Resistor Equations

$$
\begin{aligned}
& \mathrm{P}_{\mathrm{MAX}}=\frac{\mathrm{V}_{\mathrm{CC}}(\mathrm{Min})-\mathrm{V}_{\mathrm{OH}}}{\mathrm{~N}_{1}\left(\mathrm{l}_{\mathrm{OH}}\right)+\mathrm{N}_{2}\left(\mathrm{I}_{\mathrm{H}}\right)} \\
& \mathrm{R}_{\mathrm{MIN}}=\frac{\mathrm{V}_{\mathrm{CC}}(\text { Max })-\mathrm{V}_{\mathrm{OL}}}{\mathrm{IOL}_{\mathrm{OL}}-\mathrm{N}_{3}(\mathrm{IIL})}
\end{aligned}
$$

## Features

■ Switching specifications at 50 pF

- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with LS TTL counterpart
- Improved line receiving characteristics

Where: $\quad \mathrm{N}_{1}(\mathrm{l} \mathrm{OH})=$ total maximum output high current for all outputs tied to pull-up resistor
$\mathrm{N}_{2}\left(\mathrm{l}_{\mathrm{I}}\right)=$ total maximum input high current for all inputs tied to pull-up resistor
$N_{3}\left(I_{1 L}\right)=$ total maximum input low current for all inputs tied to pull-up resistor

## DM74ALS1005

Hex Inverting Driver with Open Collector Outputs

## General Description

These devices contain six independent drivers, each of which performs the logic INVERT/Complement function. The outputs require external pull-up resistors for proper logical operation. The 'ALSt005 is a driver version of the 'ALS05A.

## Pull-Up Resistor Equations

$$
\begin{aligned}
& R_{M A X}=\frac{V_{C C}(\mathrm{Min})-V_{O H}}{N_{1}\left(l_{\mathrm{OH}}\right)+N_{2}\left(l_{\mathrm{IH}}\right)} \\
& R_{\mathrm{MIN}}=\frac{V_{\mathrm{CC}}(\mathrm{Max})-V_{\mathrm{OL}}}{I_{\mathrm{OL}}-N_{3}\left(l_{\mathrm{IL}}\right)}
\end{aligned}
$$

Where: $\quad N_{1}\left({ }_{\mathrm{OH}}\right)=$ total maximum output high current for all outputs tied to pull-up resistor
$\mathrm{N}_{2}\left(\mathrm{I}_{\mathrm{I}}\right)$ ) total maximum input high current for all inputs tied to pull-up resistor
$\mathrm{N}_{3}\left(\mathrm{l}_{\mathrm{L}}\right)=$ total maximum input low current for all inputs tied to pull-up resistor

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with Schottky and low power Schottky TTL counterpart
- Improved AC performance over Schottky and low power Schottky counterparts

## DM74ALS1008A

## Quadruple 2-Input AND Buffer

## General Description

These devices contain four independent 2-input buffers, each of which performs the logic AND function. The 'ALS1008A is a buffer version of the 'ALS08.

## Features

■ Switching specifications at 50 pF

- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Improved line receiving characteristics

## Connection Diagram

Function Table

| Inputs |  |  |

[^32]DM74ALS1032A

## Quadruple 2-Input OR Buffer

## General Description

These devices contain four independent buffers, each of which performs the logic OR function. The 'ALS1032A is a buffer version of the 'ALS32.

## Features

■ Switching specifications at 50 pF

- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Improved line receiving characteristics

## Connection Diagram

TL/F/6258-1
Order Number DM74ALS1032AM or DM74ALS1032AN
See NS Package Number M14A or N14A

## Function Table

| $\mathbf{Y}=\mathbf{A}+\mathbf{B}$ |  |  |
| :---: | :---: | :---: |
| Inputs |  | Output |
| $\mathbf{A}$ | $\mathbf{B}$ |  |
| L | L | L |
| H | X | H |
| X | H | H |

$L=$ Low Logic Level
$H=$ High Logic Level
$X=$ Either Low or High Logic Level

## Absolute Maximum Ratings

| Supply Voltage | 7 V |
| :--- | ---: |
| Input Voltage | 7 V |
| Operating Free Air Temperature Range |  |
| DM74ALS | $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Typical $\theta_{\mathrm{JA}}$ |  |
| N Package | $83.0^{\circ} \mathrm{C} / \mathrm{W}$ |
| M Package | $114.0^{\circ} \mathrm{C} / \mathrm{W}$ |

Note: The "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. The device should not be operated at these limits. The parametric values defined in the "Electrical Characteristics" table are not guaranteed at the absolute maximum ratings. The "Recommended Operating Conditions" table will define the conditions for actual device operation.

Recommended Operating Conditions

## DM74ALS1240A/DM74ALS1241A

## Octal TRI-STATE ${ }^{\circledR}$ Bus Driver

## General Description

These octal TRI-STATE bus drivers are designed to provide the designer with flexibility in implementing a bus interface with memory, microprocessor, or communication systems, and are low power dissipation versions of the 'ALS240 and 'ALS241. The output TRI-STATE gating control is organized into two separate groups of four buffers. The 'ALS1240 control inputs symmetrically enable the respective outputs when set logic low, while the 'ALS1241A has complementary enable gating. The TRI-STATE circuitry contains a feature that maintains the buffer outputs in TRI-STATE (high impedance state) during power supply ramp-up or ramp-down. This eliminates bus glitching problems that arise during power-up and power-down.

## Features

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Switching response specified into $500 \Omega$ and 50 pF load
- Switching response specifications guaranteed over full temperature and $V_{C C}$ supply range
- PNP input design reduces input loading
- Low power dissipation version of the DM54/74ALS240, 241
- Low level drive current: 74ALS $=16 \mathrm{~mA}$

## DM74ALS1242A/DM74ALS1243A

Quad Bidirectional Bus Driver

## General Description

These octal TRI-STATE ${ }^{\oplus}$ bus drivers are designed to provide the designer with flexibility in implementing a bus interface with memory, microprocessor, or communication systems, and are low power dissipation versions of the 'ALS242 and 'ALS243. The 'ALS1242 has inverting buffers, while the 'ALS1243A has non-inverting buffers. The direction enable gating is configured with separate control over either buffer direction and the two control buffers are complementary. Connecting these control inputs to one common line implements single line direction control, while individual control can put both buffer directions into TRI-STATE simultaneously (disabled state) or put both buffer directions into the active state (data latch state). The TRI-STATE circuitry contains a feature that maintains the buffer outputs in TRI-STATE (high impedance state) during power supply ramp-up or ramp-down. This eliminates bus glitching problems that arise during power-up and power-down.

## Features

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Switching response specified into $500 \Omega$ and 50 pF load
- Switching response specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ supply range
- PNP input design reduces input loading
- Low power dissipation version of the DM54/74ALS242, 243
■ Low level drive current: 74ALS $=16 \mathrm{~mA}$

## DM74ALS1244A

Octal TRI-STATE ${ }^{\circledR}$ Bus Driver

## General Description

This octal TRI-STATE bus driver is designed to provide the designer with flexibility in implementing a bus interface with memory, microprocessor, or communication systems, and is a low power dissipation version of the 'ALS244. The output TRI-STATE gating control is organized into two separate groups of four buffers, and both control inputs enable the respective outputs when set logic low. The TRI-STATE circuitry contains a feature that maintains the buffer outputs in TRI-STATE (high impedance state) during power supply ramp-up or ramp-down. This eliminates bus glitching problems that arise during power-up and power-down.

## Features

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Switching response specified into $500 \Omega$ and 50 pF load
- Switching response specifications guaranteed over full temperature and $V_{C C}$ supply range
- PNP input design reduces input loading
- Low power dissipation version of the DM54/ 74ALS244A
- Low level drive current: $54 \mathrm{ALS}=8 \mathrm{~mA}, 74 \mathrm{ALS}=16 \mathrm{~mA}$

## DM74ALS2541

## Octal Buffer and MOS Line Driver with

 TRI-STATE ${ }^{\circledR}$ Outputs
## General Description

These octal buffers and line drivers are designed to have the performance of the 'ALS240 series and, at the same time, offer a pinout with inputs and outputs on opposite sides of the package. This arrangement of input/outputs enhances printed circuit board layout. These drivers are designed to drive the capacitive inputs of MOS devices. The outputs have $25 \Omega$ resistors in series, thus external components are not required. The TRI-STATE control gate is a 2input NOR such that if either $\overline{\mathrm{G}} 1$ or $\overline{\mathrm{G}} 2$ is high, all eight outputs are in the high impedance state.

## Features

- Advanced oxide-isolated ion-implanted Schottky TTL process
- Switching performance is guaranteed over full temperature and $V_{C C}$ supply range
m Data Flow-Thru Pinout (All inputs on opposite side from outputs)
- P-N-P Inputs reduce DC loading
- Outputs have $25 \Omega$ series resistors thus no external resistors are required

## Connection Diagram

## DM74ALS5245

Octal TRI-STATE ${ }^{\circledR}$ Transceiver

## General Description

This octal bus transceiver is designed for asynchronous two-way communication between data buses. The inputs include hystersis which provides improved noise rejection. Data is transmitted either from the A bus to the B bus or from the $B$ bus to the $A$ bus depending on the logic level of the direction control (DIR) input. The device can be disabled via the enable input ( $\overline{\mathrm{G}}$ ) which causes the outputs to enter the high impedance mode so the buses are effectively isolated.

## Features

- Advanced oxide-isolated, ion implanted Schottky TTL process
■ Switching specification guaranteed over the full temperature and $\mathrm{V}_{\mathrm{CC}}$ range
- PNP inputs to reduce input loading
- Input Hystersis to improve noise margin

## Connection Diagram

TL/F/9175-1
Order Number DM74ALS5245WM or DM74ALS5245N

## DM74AS00 Quad 2-Input NAND Gate

## General Description

This device contains four independent gates, each of which performs the logic NAND function.

## Features

■ Switching specifications at 50 pF

- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with Schottky, low power Schottky, and advanced low power Schottky TTL counterpart
- Improved AC performance over Schottky, low power Schottky, and advanced low power Schottky counterparts

## Connection Diagram

Order Number DM74AS00M or DM74AS00N
See NS Package Number M14A or N14A

DM74AS04 Hex Inverter

## General Description

This device contains six independent gates, each of which performs the logic INVERT function.

## Features

■ Switching specifications at 50 pF

- Switching specifications guaranteed over full temperature and $V_{C C}$ range

Advanced oxide-isolated, ion-implanted Schottky TTL process

- Functionally and pin for pin compatible with Schottky and low power Schottky TTL counterpart
- Improved AC performance over Schottky and low power Schottky counterparts

## Connection Diagram

Order Number DM74AS04M, N See NS Package Number M14A or N14A

## Function Table

| $\mathbf{Y}=\overline{\mathbf{A}}$ |  |
| :---: | :---: |
| Input | Output |
| $\mathbf{A}$ | $\mathbf{Y}$ |

## General Description

This device contains two independent 4-input gates, each of which performs the logic AND function.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range

■ Advanced oxide-isolated, ion-implanted Schottky TTL process

- Functionally and pin for pin compatible with Schottky, low power Schottky, and advanced low power Schottky TTL counterpart
- Improved AC performance over Schottky, low power Schottky and advanced low power Schottky counterparts

## Connection Diagram

## DM74AS74 Dual D Positive-Edge-Triggered Flip-Flop with Preset and Clear

## General Description

The AS74 is a dual edge-triggered flip-flops. Each flip-flop has individual $D$, clock, clear and preset inputs, and also complementary Q and $\overline{\mathrm{Q}}$ outputs.
Information at input $D$ is transferred to the $Q$ output on the positive going edge of the clock pulse. Clock triggering occurs at a voltage level of the clock pulse and is not directly related to the transition time of the positive going pulse. When the clock input is at either the high or low level, the D input signal has no effect.
Asynchronous preset and clear inputs will set or clear $Q$ output respectively upon the application of low level signal.

Features

- Switching specifications at 50 pF

■ Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin-for-pin compatible with Schottky and LS TTL counterpart
- Improved AC performance over S74 at approximately half the power

## Connection Diagram

TL/F/6282-1
Order Number DM74AS74M, N See NS Package Number M14A or N14A

## Function Table

| Inputs |  |  |  | Outputs |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\overline{\text { PR }}$ | $\overline{\text { CLR }}$ | CLK | D | Q | $\overline{\mathbf{Q}}$ |
| L | H | X | X | H | L |
| H | L | X | X | L | H |
| L | L | X | X | $\mathrm{H}^{*}$ | $\mathrm{H}^{*}$ |
| H | H | $\uparrow$ | H | H | L |
| H | H | $\uparrow$ | L | L | H |
| H | H | L | X | $Q_{0}$ | $\overline{\mathrm{Q}}_{0}$ |

L = Low State, $H=$ High State, $X=$ Don't Care
$\uparrow=$ Positive Edge Transition
$Q_{0}=$ Previous Condition of $\mathbf{Q}$

* = This condition is nonstable; it will not persist when preset and clear inputs return to their inactive (high) level. The output levels in this condition are not guaranteed to meet the $\mathrm{V}_{\mathrm{OH}}$ specification.

## Absolute Maximum Ratings

| Supply Voltage | 7 V |
| :--- | ---: |
| Input Voltage | 7 V |
| Operating Free Air Temperature Range | $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Typical $\theta_{\text {JA }}$ |  |
| N Package | $76.0^{\circ} \mathrm{C} / \mathrm{W}$ |
| M Package | $107.0^{\circ} \mathrm{C} / \mathrm{W}$ |

Note: The "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. The device should not be operated at these limits. The parametric values defined in the "Electrical Characteristics" table are not guaranteed at the absolute maximum ratings. The "Recommended Operating Conditions" table will define the conditions for actual device operation.

Recommended Operating Conditions

| Symbol | Parameter |  | Min | Nom | Max | Units |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## DM74AS109 Dual J-K Positive-Edge-Triggered Flip-Flop with Preset and Clear

## General Description

The 'AS109 is a dual edge-triggered flip-flop. Each flip-flop has individual $J, \bar{K}$, clock, clear and preset inputs, and also complementary Q and $\overline{\mathrm{Q}}$ outputs.
Information at inputs $J$ and $\bar{K}$ meeting the setup time requirements are transferred to the $Q$ output on the positive going edge of the clock pulse. Clock triggering occurs at a voltage level of the clock pulse and is not directly related to the transition time of the positive going pulse. When the clock input is at either the high or low level, the $\mathrm{J}, \overline{\mathrm{K}}$ input signal has no effect.
Asynchronous preset and clear inputs will set or reset $Q$ output respectively upon the application of low level signal. The J- $\bar{K}$ design allows operation as a $D$ flip-flop by tying the J and $\overline{\mathrm{K}}$ inputs together.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with Schottky and LS TTL counterpart
- Improved AC performance over S109 at approximately half the power

## Logic Diagram

## DM74AS136 Quad 2-Input <br> Exclusive-OR Gate with Open-Collector Outputs

## General Description

This device contains four independent gates, each of which performs the logic exclusive-OR function. The open-collector outputs require external pull-up resistors for proper logical operation.

## Pull-Up Resistor Equations

$$
\begin{aligned}
& R_{\mathrm{MAX}}=\frac{V_{\mathrm{CC}}(\mathrm{Min})-V_{\mathrm{OH}}}{N_{1}\left(\mathrm{lOH}_{\mathrm{OH}}\right)+N_{2}\left(\mathrm{l}_{\mathrm{H}}\right)} \\
& \mathrm{R}_{\mathrm{MIN}}=\frac{\mathrm{V}_{\mathrm{CC}}(\mathrm{Max})-\mathrm{V}_{\mathrm{OL}}}{I_{\mathrm{OL}}-\mathrm{N}_{3}(\mathrm{llL})}
\end{aligned}
$$

Where: $\quad N_{1}\left(\mathrm{l}_{\mathrm{OH}}\right)=$ total maximum output high current for all outputs tied to pull-up resistor
$\mathrm{N}_{2}\left(\mathrm{I}_{\mathrm{H}}\right)=$ total maximum input high current for all inputs tied to pull-up resistor
$N_{3}\left(I_{1}\right)=$ total maximum input low current for all inputs tied to pull-up resistor

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with Schottky, low power Schottky, and advanced low power Schottky TTL counterparts
- Improved AC performance over Schottky, low power Schottky, and advanced low power Schottky counterparts
- Open collector outputs for wired AND cascading

PNP input design reduces input loading

## DM74AS157/DM74AS158 <br> Quad 1 of 2 Line Data Selector/Multiplexer

## General Description

These data selectors/multiplexers contain inverters and drivers to supply full on-chip data selection to the four output gates. A separate STROBE input is provided. A 4-bit word is selected from one of two sources and is routed to the four outputs. The AS157 presents true data whereas the AS158 presents inverted data to minimize propagation delay time.

## Features

■ Switching specifications at 50 pF

- Switching specifications guaranteed over full temperature and $V_{C C}$ range

■ Advanced oxide-isolated, ion-implanted Schottky TTL process

- Functionally and pin for pin compatible with Schottky, low power Schottky, and advanced low power Schottky TTL counterpart
- Improved AC performance over Schottky, low power Schottky, and advanced low power Schottky counterparts
- Expand any data input point
m Multiplex dual data buses
- General four functions of two variables (one variable is common)
m Source programmable counters

## Connection Diagram

## Function Table

| Inputs |  |  |  | Output Y |  |

Logic Diagrams

TL/F/6290-2

## General Description

These synchronous presettable counters feature an internal carry look ahead for application in high speed counting de－ signs．The AS160 and AS162 are four－bit decade counters， while the AS161 and AS163 are four－bit binary counters． The AS160 and AS161 clear asynchronously，while the AS162 and AS163 clear synchronously．The carry output is decoded to prevent spikes during normal counting mode of operation．Synchronous operation is provided by having all flip－flops clocked simultaneously so that outputs change co－ incident with each other when so instructed by count enable inputs and internal gating．This mode of operation elimi－ nates the output counting spikes which are normally associ－ ated with asynchronous（ripple clock）counters．A buffered clock input triggers the four flip－flops on the rising（positive－ going）edge of the clock input waveform．
These counters are fully programmable，that is，the outputs may each be preset to either level．As presetting is synchro－ nous，setting up a low level at the LOAD input disables the counter and causes the outputs to agree with set up data after the next clock pulse regardless of the levels of enable input．Low to high transitions at the $\overline{\text { LOAD }}$ input are perfectly acceptable regardless of the logic levels on the clock or enable inputs．

## General Description (Continued)

The AS160 and AS161 clear function is asynchronous. A low level at the clear input sets all four of the flip-flop outputs low regardless of the levels of clock, load or enable inputs. These two counters are provided with a clear on power-up feature. The AS162 and AS163 clear function is synchronous; and a low level at the clear input sets all four of the flip-flop outputs low after the next clock pulse, regardless of the levels of enable inputs. This synchronous clear allows the count length to be modified easily, as decoding the maximum count desired can be accomplished with one external NAND gate. The gate output is connected to the clear input to synchronously clear the counter to all low outputs. Low to high transitions at the clear input of the AS162 and AS163 are also permissible regardless of the levels of logic on the clock, enable or load inputs.
The carry look ahead circuitry provides for cascading counters for n bit synchronous application without additional gating. Instrumental in accomplishing this function are two
count-enable inputs ( $P$ and $T$ ) and a ripple carry output. Both count-enable inputs must be high to count. The T input is fed forward to enable the ripple carry output. The ripple carry output thus enabled will produce a high level output pulse with a duration approximately equal to the high level portion of QA output. This high level overflow ripple carry pulse can be used to enable successive cascaded stages. High to low level transitions at the enable $P$ or $T$ inputs of the AS160 through AS163, may occur regardless of the logic level on the clock.
The AS160 through SA163 feature a fully independent clock circuit. Changes made to control inputs (enable P or T, or load) that will modify the operating mode will have no effect until clocking occurs. The function of the counter (whether enabled, disabled, loading or counting) will be dictated solely by the conditions meeting the stable set-up and hold times.

## DM74AS168A/DM74AS169A Synchronous Four Bit Up/Down Counter

## General Description

These synchronous presettable counters feature an internal carry look ahead for cascading in high speed counting applications. The AS168 is a four-bit decade up/down counter and the AS169 is a four-bit binary up/down counter. The carry output is decoded to prevent spikes during normal mode of counting operation. Synchronous operation is provided so that outputs change coincident with each other when so instructed by count enable inputs and internal gating. This mode of operation eliminates the output counting spikes which are normally associated with asynchronous (ripple clock) counters. A buffered clock input triggers the four flip-flops on the rising (positive going) edge of clock input waveform.
These counters are fully programmable; that is, the outputs may each be preset either high or low. The load input circuitry allows loading with carry-enable output of cascaded counters. As loading is synchronous, setting up a low level at the load input disables the counter and causes the outputs to agree with the data inputs after the next clock pulse. The carry look-ahead circuitry permits cascading counters for $n$-bit synchronous applications without additional gating. Both count enable inputs ( $\overline{\mathrm{P}}$ and $\overline{\mathrm{T}}$ ) must be low to count. The direction of the count is determined by the level of the up/down input. When the input is high, the counter counts up; when low, it counts down. Input T is fed forward to enable the carry outputs. The carry output thus enabled will produce a low level output pulse with a duration approximately equal to the high portion of the QA output when counting up, and approximately equal to the low portion of
the QA output when counting down. This low level overflow carry pulse can be used to enable successively cascaded stages. Transitions at the enable $\overline{\mathrm{P}}$ or $\overline{\mathrm{T}}$ inputs are allowed regardless of the level of the clock input.
The control functions for these counters are fully synchronous. Changes at control inputs (enable $\overline{\mathrm{P}}$, enable $\overline{\mathrm{T}}$, load, up/down) which modify the operating mode have no effect until clocking occurs. The function of the counter (whether enabled, disabled, loading or counting) will be dictated solely by the conditions meeting the stable setup and hold times.

## Features

| ${ }^{\text {t }}$ HLL | Propagation Delay Time High to Low Level Output |  | En ${ }^{\text {T }}$ | RIPPLE Carry | 1.5 | 9 | ns |
| ${ }^{\text {PLLH }}$ | Propagation Delay Time Low to High Level Output |  | $U / \bar{D}$ (Note 2) | RIPPLE Carry | 2 | 12 | ns |
| ${ }_{\text {t }}^{\text {PHL }}$ | Propagation Delay Time High to Low Level Output |  | $\begin{gathered} U / \bar{D} \\ \text { (Note 2) } \end{gathered}$ | हIPPLE <br> Carry | 2 | 13 | ns |

Note 1: See Section 1 for test waveforms and output load.
Note 2: Propagation delay time from up/down to ripple carry must be measured with the counter at either a minimum or a maximum count. As the logic level of the up/down input is changed, the ripple carry output will follow. If the count is minimum ( 0 ), the ripple carry output transition will be in phase. If the count is maximum ( 9 for AS168A or 15 for AS169A), the ripple carry output will be out of phase.

## DM74AS174 Hex D Flip－Flop with Clear

## General Description

These positive－edge－triggered flip－flops utilize TTL circuitry to implement D－type flip－flop logic．This device has an asyn－ chronous clear input．
Information at the $D$ inputs meeting the setup time require－ ments is transferred to the Q outputs on the positive－going edge of the clock pulse．Clock triggering occurs at a particu－ lar voltage level and is not directly related to the transition time of the positive－going pulse．When the clock input is at either a high or low level，the $D$ input signal has no effect at the output．

## Features

－Advanced oxide－isolated，ion－implanted Schottky TTL process
－Pin and functional compatible with LS and Schottky family counterpart
－Switching performance guaranteed over full tempera－ ture and $V_{C C}$ supply range

## Connection Diagram

## Function Table

| Inputs |  |  | Output |
| :---: | :---: | :---: | :---: |
| CLEAR | Clock | D | Q |
| L | X | X | L |
| H | $\uparrow$ | H | H |
| H | $\uparrow$ | L | L |
| H | L | X | $Q_{0}$ |

$H=$ High Logic State
$\mathrm{L}=$ Low Logic State
$X=$ Either Low or High Logic State
$Q_{0}=$ The level of $Q$ before the indicated steady－state input conditions were established．
$\uparrow=$ Transition from Low Logic Level to High Logic Level

## DM74AS181B Arithmetic Logic <br> Unit/Function Generator

## General Description

These arithmetic logic units (ALU)/function generators perform 16 binary arithmetic operations on two 4-bit words, as shown in Tables I and II. These operations are selected by the four function-select lines (S0, S1, S2, S3) and include addition, subtraction, decrement, and straight transfer. When performing arithmetic manipulations, the internal carries must be enabled by applying a low-level voltage to the mode control input (M). A full carry look-ahead scheme is available in these devices for fast, simultaneous carry generation by means of two cascade-outputs ( P and G ) for the four bits in the package. When used in conjunction with the DM74AS182 full carry look-ahead circuits, high-speed arithmetic operations can be performed. The typical addition times shown in Table III illustrate how little time is required for addition of longer words, when full carry look-ahead is employed. The method of cascading AS182 circuits with these ALU's to provide multi-level full carry look-ahead is illustrated under typical applications data for the DM74AS182.
(Continued)

## Connection Diagram

TL/F/6295-1
Order Number DM74AS181BN, NT See NS Package Number N24A or N24C

## Features

- Arithmetic operating modes: Addition
Subtraction
Shift operand A one position
Magnitude comparison
Plus twelve other arithmetic operations
- Logic function modes:

EXCLUSIVE-OR
Comparator
AND, NAND, OR, NOR
Plus ten other logic operations
m Full look-ahead for high-speed operations on long words

- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Switching specifications at $500 \Omega / 50 \mathrm{pF}$
■ Advanced oxide-isolated, ion-implanted Schottky TTL process

## Absolute Maximum Ratings

## General Description (Continued)

If high speed is not important, a ripple-carry input $\left(C_{n}\right)$ and a ripple-carry output ( $\mathrm{C}_{n}+4$ ) are available. However, the rip-ple-carry delay has also been minimized so that arithmetic manipulations for small word lengths can be performed without external circuitry.
These circuits will accommodate active-high or active-low data, if the pin designations are interpreted as shown below.
Subtraction is accomplished by 1 's complement addition, where the 1 's complement of the subtrahend is generated internally. The resultant output is $\mathrm{A}-\mathrm{B}-1$, which requires an end-around or forced carry to provide A-B.
The AS181B can also be utilized as a comparator. The $\mathrm{A}=$ B output is internally decoded from the function outputs (FO, F1, F2, F3) so that when two words of equal magnitude are applied at the $A$ and $B$ inputs, it will assume a high level to indicate equality $(A=B)$. The $A L U$ should be in the subtract mode with $\mathrm{C}_{\mathrm{n}}=\mathrm{H}$ when performing this comparison. The $\mathrm{A}=\mathrm{B}$ output is open-collector so that it can be wire-AND connected to give a comparison for more than four bits. The carry output ( $\mathrm{C}_{n}+4$ ) can also be used to supply
relative magnitude information. Again, the ALU should be placed in the subtract mode by placing the function select inputs S3, S2, S1, S0 at L, H, H, L, respectively.
These circuits have been designed to not only incorporate all of the designer's requirements for arithmetic operations, but also to provide 16 possible functions of two Boolean variables without the use of external circuitry. These logic functions are selected by use of the four function-select inputs (S0, S1, S2, S3) with the mode-control input (M) at a high level to disable the internal carry. The 16 logic functions are detailed in Tables I and II and include exclusiveOR, NAND, AND, NOR, and OR functions.

## ALU SIGNAL DESIGNATIONS

The TTL S181 and AS181B can be used with the signal designations of either Figure 1 or Figure 2.
The logic functions and arithmetic operations obtained with signal designations as in Figure 1 are given in Table l; those obtained with the signal designations of Figure 2 are given in Table II.

TABLE III

| Number of Bits | Typical Addition Times Using AS181B \& AS882 | Package Count |  | Carry Method Between ALU's |
| :---: | :---: | :---: | :---: | :---: |
|  |  | Arithmetic/ Logic Units | Look Ahead Carry Generators |  |
| 1 to 4 | 5 ns | 1 | 0 | None |
| 5 to 8 | 10 ns | 2 | 0 | Ripple |
| 9 to 16 | 14 ns | 3 or 4 | 1 | Full Look-Ahead |
| 17 to 64 | 101 ns | 5 to 16 | 2 to 5 | Full Look-Ahead |

## Logic Diagram

TL/F/6295-4

## DM74AS182 Look-Ahead Carry Generator

## General Description

These circuits are high-speed, look-ahead carry generators, capable of anticipating a carry across four binary adders or groups of adders. They are cascadable to perform full lookahead across n-bit adders. Carry, generate-carry, and prop-agate-carry functions are provided as shown in the pin designation table.
When used in conjunction with the AS181B arithmetic logic unit, these generators provide high-speed carry look-ahead capability for any word length. Each AS182 generates the look-ahead (anticipated carry) across a group of four ALUs and, in addition, other carry look-ahead circuits may be employed to anticipate carry across sections of four lookahead packages up to $n$-bits. The method of cascading circuits to perform multi-level look-ahead is illustrated under typical application data.
Carry input and output of the ALUs are in their true form, and the carry propagate $(\bar{P})$ and carry generate $(\bar{G})$ are in negated form; therefore, the carry functions (inputs, outputs, generate, and propagate) of the look-ahead generators are implemented in the compatible forms for direct connection to the ALU. Reinterpretations of carry functions, as explained on the 181 data sheet are also applicable to and
compatible with the look-ahead generator. Positive logic equations for the AS182 are:
$\mathrm{C}_{\mathrm{n}+\mathrm{x}}=\mathrm{G} 0+\mathrm{PO} \mathrm{C}_{\mathrm{n}}$
$\mathrm{C}_{\mathrm{n}+\mathrm{y}}=\mathrm{G} 1+\mathrm{P} 1 \mathrm{G} 0+\mathrm{P} 1 \mathrm{P} 0 \mathrm{C}_{\mathrm{n}}$
$\mathrm{C}_{\mathrm{n}+\mathrm{z}}=\mathrm{G} 2+\mathrm{P} 2 \mathrm{G} 1+\mathrm{P} 2 \mathrm{P} 1 \mathrm{G} 0+\mathrm{P} 2 \mathrm{P} 1 \mathrm{P} 0 \mathrm{C}_{\mathrm{n}}$
$\overline{\mathrm{G}}=\overline{\mathrm{G} 3+\mathrm{P} 3 \bullet \mathrm{G} 2+\mathrm{P} 3 \cdot \mathrm{P} 2 \bullet \mathrm{G} 1+\mathrm{P} 3 \cdot \mathrm{P}^{\bullet} \bullet \mathrm{P}^{1} \bullet \mathrm{G0}}$
$\overline{\mathrm{P}}=\overline{\mathrm{P} 3 \mathrm{P} 2 \mathrm{P} 1 \mathrm{P0}}$

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- Offers carry functions in a compatible form for direct connection to the ALU
- Cascadable to perform look-ahead across n-bit adders
- PNP inputs reduce input loading
- Improved AC performance over Schottky at reduced power consumption

## DM74AS230/DM74AS231

TRI-STATE ${ }^{\circledR}$ Bus Driver/Receiver

## General Description

This family of Advanced Schottky TRI-STATE Bus circuits are designed to provide either bidirectional or unidirectional buffer interface in Memory, Microprocessor, and Communication Systems. The output characteristics of the circuits have low impedance sufficient to drive terminated transmission lines down to 133 ohms. The input characteristics of the circuits likewise have a high impedance so it will not significantly load the transmission line. The package contains eight TRI-STATE buffers organized with four buffers having a common TRI-STATE enable gate. The AS230 is organized as 4 bit buffers inverting and 4 bit buffers non inverting. The AS231 is organized as two 4 bit wide inverting buffers with separate complementary output control buffers.

## Features

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Improved switching performance over low power Schottky counterpart
- Functional and pin compatible with low power Schottky counterpart
- Switching response specified into $500 \Omega$ and 50 pF
- Low level drive current 74AS $=48 \mathrm{~mA}$
- Specified to interface with CMOS at $\mathrm{V}_{\mathrm{OH}}=\mathrm{V}_{\mathrm{CC}}-2 \mathrm{~V}$

## DM74AS240, 241, 242, 243, 244 TRI-STATE ${ }^{\circledR}$ Bus Driver/Receiver

## General Description

This family of Advance Schottky TRI-STATE Bus circuits are designed to provide either bidirectional or unidirectional buffer interface in Memory, Microprocessor, and Communication Systems. The output characteristics of the circuits have low impedance sufficient to drive terminated transmission lines down to 133 ohms. The input characteristics of the circuits likewise have a high impedance so it will not significantly load the transmission line. The package contains eight TRI-STATE buffers organized with four buffers having a common TRI-STATE enable gate. The AS240, 241 and 244 are eight wide in a 20 pin package, and may be used as a 4 wide bidirectional or eight wide unidirectional. The AS242 and 243 are organized four wide bidirectional in a 14 pin package. The buffer selection includes inverting and non-inverting, with enable or disable TRI-STATE control.

## Features

■ Advanced oxide-isolated, ion-implanted Schottky TTL process

- Improved switching performance with less power dissipation compared with Schottky counterpart
- Functional and pin compatible with 54/74LS and Schottky counterpart
- Switching response specified into 500 ohm and 50 pF

■ Specified to interface with CMOS at $\mathrm{V}_{\mathrm{OH}}=\mathrm{V}_{\mathrm{CC}}-2 \mathrm{~V}$

Note: The "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. The device should not be operated at these limits. The parametric values defined in the "Electrical Characteristics" table are not guaranteed at the absolute maximum ratings. The "Recommended Operating Conditions" table will define the conditions for actual device operation.

## DM74AS245

## Octal Bus Transceiver with TRI-STATE® Outputs

## General Description

This advanced Schottky device contains 8 pairs of TRISTATE logic elements configured as octal bus transceivers. These circuits are designed for use in memory, microprocessor systems and in asynchronous bidirectional data buses. Two way communication between buses is controlled by the (DIR) input. Data transmits either from the A bus to the $B$ bus or from the $B$ bus to the $A$ bus. Both the driver and receiver outputs can be disabled via the ( $\overline{\mathrm{G}}$ ) enable input which causes outputs to enter the high impedance mode so that the buses are effectively isolated.

## Features

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Non-inverting logic output
- TRI-STATE outputs independently controlled on A and B buses
- Low output impedance to drive terminated transmission lines to $133 \Omega$
- Switching response specified into $500 \Omega / 50 \mathrm{pF}$
- Specified to interface with CMOS at $\mathrm{V}_{\mathrm{OH}}=\mathrm{V}_{\mathrm{CC}}-2 \mathrm{~V}$
- PNP inputs reduce input loading

■ Switching specifications guaranteed over full temperature and $V_{C C}$ range

## Connection Diagram

Dual-In-Line Package

## DM74AS257/DM74AS258 TRI-STATE ${ }^{\circledR}$ Quad 1 of 2 Line Data Selector/Multiplexer

## General Description

These data selectors/multiplexers contain inverters and drivers to supply full on-chip data selection to the four TRI-STATE outputs that can interface directly with data lines of bus-organized systems. A 4-bit word selected from one of two sources is routed to the four outputs. The AS257 presents true data whereas the AS258 presents inverted data to minimize propagation delay time.
This TRI-STATE output feature means that n-bit (paralleled) data selectors with up to 300 sources can be implemented for data buses. It also permits the use of standard TTL registers for data retention throughout the system.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with Schottky, low power Schottky, and advanced low power Schottky TTL counterpart
- Improved AC performance over Schottky, low power Schottky, and advanced low power Schottky counterparts
- TRI-STATE buffer-type output drive bus lines directly
- Expand any data input point
- Multiplex dual data buses
- General four functions of two variables (one variable is common)
- Source programmable counters

## Connection Diagram

Order Number DM74AS257N or DM74AS258N
See NS Package Number N16A*

## DM74AS264 Look-Ahead Carry Generator

## General Description

This circuit is a high speed, look-ahead carry generator capable of anticipating a carry across four counters. It is cascadable to perform look-ahead across N -bit counters. Carry, generator-carry and propagate-carry output functions are provided as shown in the connection diagram.
This circuit can accommodate counters which have either low level carry pulse or high level carry pulse outputs, and can provide high speed carry look-ahead capability for any word length. Each AS264 generates the look-ahead (anticipated carry) across a group of four counters, and in addition, other carry look-ahead circuits may be employed to anticipate a carry across sections of four look-ahead packages up to N bits. This method of cascading circuits to perform multi-level look-ahead is illustrated under Typical Applications.

## Features

- Advanced oxide-isolated, ion implanted Schottky TTL process
- Switching specification at 50 pF
- Switching specifications guaranteed over full temperature range and $V_{C C}$ range
- PNP inputs reduce input loading

## Connection Diagram

## Absolute Maximum Ratings

| Supply Voltage, VCC | 7 V |
| :--- | ---: |
| Input Voltage | 7 V |
| Operating Free Air Temperature | $0^{\circ} \mathrm{C}$ to $70^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Typical $\theta_{J A}$ |  |
| N Package | $67.0^{\circ} \mathrm{C} / \mathrm{W}$ |

Note: The "Absolute Maximum Ratings" are those values beyond which the safety of the device can not be guaranteed. The device should not be operated at these limits. The parametric values defined in the "Electrical Characteristics" table are not guaranteed at the absolute maximum ratings. The "Recommended Operating Conditions" table will define the conditions for actual device operation.

## Recommended Operating Conditions

## DM74AS280 9-Bit Parity Generator/Checker

## General Description

These universal, 9-bit parity generators/checkers utilize advanced Schottky high performance circuitry and feature odd/even outputs to facilitate operation of either odd or even parity applications. The word length capability is easily expanded by cascading.
The AS280 can be used to upgrade the performance of most systems utilizing the '180 parity generator/checker. Although the AS280 is implemented without expander inputs, the corresponding function is provided by the availability of an input at pin 4 and no internal connection at pin 3. This permits the AS280 to be substituted for the ' 180 in existing designs to produce identical function even if 'AS280s are mixed with existing '180s.

## Connection Diagram

Dual-In-Line Package

TL/F/6303-1
Order Number DM74AS280M
or DM74AS280N
See NS Package Number M14A or N14A

## Features

- Generates either odd or even parity for nine data lines
- Inputs are buffered to lower the drive requirements
- Can be used to upgrade existing systems using MSI parity circuits
- Cascadable for N -bits

E Advanced oxide-isolated, ion-implanted Schottky TTL process

- Switching specifications at 50 pF

■ Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range

## Function Table

| Number of Inputs (A <br> thru I) that are High | Outputs |  |
| :---: | :---: | :---: |

## Logic Diagram

TL/F/6303-2

## Typical Applications

Three AS280s can be used to implement a 25 -line parity generator/checker.
As an alternative, the outputs of two or three parity generators/checkers can be decoded with a 2-input (AS86) or 3-input (S135) exclusive-OR gate for 18 or 27 -line parity applications.

Longer word lengths can be implemented by cascading AS280s. As shown in Figure 2, parity can be generated for word lengths up to 81 bits.

## DM74AS282 Look-Ahead Carry Generator with Selectable Carry Inputs

## General Description

This circuit is a high-speed, look-ahead carry generator capable of anticipating a carry across four binary adders or groups of adders. It is cascadable to perform full look-ahead across $n$-bit adders. Carry, generate-carry, and propagatecarry functions are provided.
When used in conjunction with the 'AS881 arithmetic logic unit, this generator provides high-speed carry look-ahead capability for any word length. Each 'AS282 generates the look-ahead (anticipated carry) across a group of four ALUs and, in addition, other carry look-ahead circuits may be employed to anticipate carry across sections of four lookahead packages up to $n$ bits. The method of cascading circuits to perform multi-level look-ahead is illustrated under Typical Applications. <br> \section*{\section*{Connection Diagram <br> \section*{\section*{Connection Diagram <br> <br> Dual-In-Line Package} <br> <br> Dual-In-Line Package}

Order Number DM74AS282N
See NS Package Number N20A*

The carry functions (inputs, outputs, generate and propagate) of the look-ahead generator are implemented in compatible forms for direct connection to the 'AS881 ALU. The carry inputs are selectable in either active high or active low.

## Features

■ Selectable input version of 'AS182 allows double precision carry
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
■ Switching specification at 50 pF
■ Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range

- PNP inputs reduce input loading

## DM74AS286 9-Bit Parity Generator/Checker with Bus-Driver Parity I/O Port

## General Description

These universal, 9-bit parity generators/checkers utilize advanced Schottky high performance circuitry and feature odd/even outputs to facilitate operation of either odd or even parity applications. The word length capability is easily expanded by cascading.
The 'AS286 can be used to upgrade the performance of most systems utilizing the 'AS180, 'AS280 parity generator/ checker. Although the 'AS286 is implemented without expander inputs, the corresponding function is provided by the availability of an input pin XMIT. XMIT is a control line which makes parity error output active and parity an input port when "high"; when "low", parity error output is inactive and parity becomes an output port. In addition, parity I/O control circuitry contains a feature to keep the I/O port in the TRI-STATE ${ }^{\circledR}$ during power up or down to prevent bus glitches.

## Features

- PNP inputs to reduce bus loading
- Generates either odd or even parity for nine data lines
- Inputs are buffered to lower the drive requirements
- Can be used to upgrade existing systems using MSI parity circuits
- Cascadable for n-bits
- Switching specifications at 50 pF

■ Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range

- A parity I/O portable to drive bus

## Connection Diagram

## $M$ National Semiconductor <br> DM74AS373 Octal D-Type Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These 8-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight latches of the AS373 are transparent D-type latches, meaning that while the enable $(G)$ is high the $Q$ outputs will follow the data ( D ) inputs. When the enable is taken low the output will be latched at the level of the data that was set up.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.

The output control does not affect the internal operation of the latches. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

■ Switching specifications at 50 pF
■ Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process

- Functionally and pin for pin compatible with LS and ALS TTL counterparts
- Improved AC performance over LS and ALS TTL counterparts
■ TRI-STATE buffer-type outputs drive bus lines directly

## Connection Diagram

## DM74AS374 Octal D-Type Edge-Triggered Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These 8-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight flip-flops of the AS374 are edge-triggered D-type flip-flops. On the positive transition of the clock, the Q outputs will be set to the logic states that were set up at the D inputs.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.

The output control does not affect the internal operation of the flip-flops. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin-for-pin compatible with LS and ALS TTL counterparts
- Improved AC performance over LS and ALS TTL counterparts
- TRI-STATE buffer-type outputs drive bus lines directly

## DM74AS533 Octal D-Type Transparent Latch with TRI-STATE® Outputs

## General Description

These 8-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight inverting latches of the AS533 are transparent $D$ type latches, meaning that while the enable $(G)$ is high the $\bar{Q}$ outputs will follow the complement of the data (D) inputs. When the enable is taken low the output will be latched at the complement of the level of the data that was set up.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic
levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.
The output control does not affect the internal operation of the latches. That is, the old data can be retained or new data can be entered even while the outputs are off.

## Features

■ Switching specifications at 50 pF
■ Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range

- Advanced oxide-isolated, ion-implanted Schottky TTL process
- TRI-STATE buffer-type outputs drive bus lines directly

## DM74AS534 Octal D-Type Edge-Triggered Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These 8-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight flip-flops of the AS534 are edge-triggered inverting D-type flip-flops. On the positive transition of the clock, the $\bar{Q}$ outputs will be set to the complement of the logic states that were set up at the $D$ inputs.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic
levels) or a high impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.
The output control does not affect the internal operation of the flip-flops. That is, the old data can be retained or new data can be entered even while the outputs are off.

## DM74AS573 Octal D-Type Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These 8-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight latches of the AS573 are transparent D-type latches, meaning that while the enable $(\mathrm{G})$ is high the Q outputs will follow the data (D) inputs. When the enable is taken low the output will be latched at the level of the data that was set up.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.

The output control does not affect the internal operation of the latches. That is, the old data can be retained or new data can be entered even while the outputs are off.
The pin-out is arranged to ease printed circuit board layout. All data inputs are on one side of the package while all the outputs are on the other side.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally equivalent with S373

■ Improved AC performance over S373 at approximately half the power

- TRI-STATE buffer-type outputs drive bus lines directly
- Bus structured pinout

## DM74AS574 Octal D-Type Edge-Triggered Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These 8-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight flip-flops of the AS574 are edge-triggered D-type flip-flops. On the positive transition of the clock, the Q outputs will be set to the logic states that were set up at the $D$ inputs.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.

The output control does not affect the internal operation of the flip-flops. That is, the old data can be retained or new data can be entered even while the outputs are off.
The pinout is arranged to ease printed circuit board layout. All data inputs are on one side of the package while all the outputs are on the other side.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally equivalent with S374
- Improved AC performance over S374 at approximately half the power
- TRI-STATE buffer-type outputs drive bus lines directly
- Bus structured pinout

## DM74AS577 Octal D-Type Edge-Triggered Flip-Flop with Inverted Outputs and Synchronous Preset

## General Description

These 8 -bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight flip-flops of the AS577 are edge-triggered inverting D-type flip-flops. On the positive transition of the clock, the Q outputs will be set to the complement of the logic states that were set up at the $\overline{\mathrm{D}}$ inputs.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.

The output control does not affect the internal operation of the flip-flops. That is, the old data can be retained or new data can be entered even while the outputs are off.
When the CLR is held on during a positive transition of the clock the $\overline{\mathrm{Q}}$ outputs of the flip-flops with go high.
The pinout is arranged to ease printed circuit board layout. All data inputs are on one side of the package, while all the outputs are on the other side.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
( Advanced oxide-isolated, ion-implanted Schottky TTL process
- TRI-STATE buffer-type outputs drive bus lines directly
- Synchronous preset
- Bus structured pinout

## National Semiconductor <br> DM74AS580 Octal D-Type Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These 8-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight inverting latches of the AS580 are transparent D-type latches, meaning that while the enable ( G ) is high the Q outputs will follow the complement of the data (D) inputs. When the enable is taken low the output will be latched at the complement of the level of the data that was set up.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high-impedance state. In the high-impedance
state the outputs neither load nor drive the bus lines significantly.
The output control does not affect the internal operation of the latches. That is, the old data can be retained or new data can be entered even while the outputs are off.
The pinout is arranged to ease printed circuit board layout. All data inputs are on one side of the package while all the outputs are on the other side.

## DM74AS620 Octal Bus Transceiver

## General Description

This octal bus transceiver is designed for asynchronous two-way communication between data buses. The control function implementation allows for maximum flexibility in timing.
This device allows data transmission from the A bus to the B bus or from the B bus to the A bus, depending upon the logic levels at the enable inputs ( $\bar{G} B A$ and GAB).
The enable inputs can be used to disable the device so that the buses are effectively isolated.
The dual-enable configuration gives the octal bus transceivers the capability of storing data by simultaneous enabling of $\bar{G} B A$ and GAB. Each output reinforces its input in this
transceiver configuration. Thus, when both control inputs are enabled and all other data sources to the two sets of bus lines are at high impedance, both sets of bus lines (16 in all) will remain at their last states.

## Features

- Local bus-latch capability
- Choice of true or inverting logic

■ Advanced oxide-isolated, ion-implanted Schottky TTL process

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range

## DM74AS640 TRI-STATE ${ }^{\circledR}$ Octal Bus Transceiver

## General Description

This advanced Schottky device contains 8 pairs of TRISTATE logic elements configured as octal bus transceiver. This circuit is designed for use in memory, microprocessor systems and in asynchronous bidirectional data buses. This device transmits data from the A bus to the B bus, or vice versa, depending upon the logic level of the direction control input (DIR). The enable input ( $\overline{\mathrm{G}}$ ) can be used to disable the devices, effecting isolation of buses A and B .
The TRI-STATE circuitry also contains a protection feature that prevents these transceivers from glitching the bus during power-up or power-down.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with Schottky, low power Schottky, and advanced low power Schottky TTL counterpart
- Improved AC performance over Schottky, low power Schottky, and advanced low power Schottky counterparts
- TRI-STATE outputs independently controlled on A and B buses
- Low output impedance drive to drive terminated transmission lines to $133 \Omega$
- Specified to interface with CMOS at $\mathrm{V}_{\mathrm{OH}}=\mathrm{V}_{\mathrm{CC}}-2 \mathrm{~V}$

## DM74AS646/DM74AS648 Octal Bus Transceiver and Register

## General Description

This device incorporates an octal bus transceiver and an octal D-type register configured to enable multiplexed transmission of data from bus to bus or internal register to bus. This bus transceiver features totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance third state and increased high-logic-level drive provide this device with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. It is particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The registers in the AS646, 648 are edge-triggered D-type flip-flops. On the positive transition of the clock (CAB or CBA), the input bus data is stored.
The SAB and SBA control pins are provided to select whether real-time data or stored data is transferred. A low input level selects real-time data, and a high level selects stored data. The select controls have a "make before break" configuration to eliminate a glitch which would normally occur in a typical multiplexer during the transition between stored and real-time data.

The enable $\overline{\mathrm{G}}$ and direction control pins provide four modes of operation; real-time data transfer from bus $A$ to $B$, realtime data transfer from bus $B$ to $A$, real-time bus $A$ and/or $B$ data transfer to internal storage, or internal store data transfer to bus A or B.
When the enable $\bar{G}$ pin is low, the direction pin selects which bus receives data. When the enable $\overline{\mathrm{G}}$ pin is high, both buses become disabled yet their input function is still enabled.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin-for-pin compatible with LS TTL counterpart
- TRI-STATE® ${ }^{\circledR}$ buffer-type outputs drive bus lines directly

AS648

National Semiconductor

## DM74AS651/DM74AS652 Octal

Bus Transceiver and Register

## General Description

These devices incorporate an octal transceiver and an octal D-type register configured to enable transmission of data from bus to bus or internal register to bus.
These bus transceivers feature totem-pole TRI-STATE® outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these devices with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.

The registers in the AS651, 652 are edge-triggered D-type flip-flops. On the positive transition of the clock (CAB or CBA), the input data is stored.
The SAB and SBA control pins are provided to select whether real-time data or stored data is transferred. A low input level selects real-time data and a high level selects stored data. The select controls have a "make before
break" configuration to eliminate a glitch which would normally occur in a typical multiplexer during the transition between stored and real-time data.
The Enable ( GAB and $\overline{\mathrm{G}} \mathrm{BA}$ ) control pins provide four modes of operation; real-time data transfer from bus $A$ to $B$, real-time data transfer from bus B to A , real-time bus A and/ or $B$ data transfer to internal storage, or internal stored data transfer to bus A and/or B.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- TRI-STATE ${ }^{\circledR}$ buffer-type outputs drive bus lines directly

## Connection Diagram

## Dual-In-Line Package

## Absolute Maximum Ratings

| Supply Voltage | 7 V |
| :--- | ---: |
| Input Voltage |  |
| Control Inputs | 7 V |
| I/O Ports | 5.5 V |
| Operating Free Air Temperature Range | $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Typical $\theta_{\text {JA }}$ |  |
| N Package | $41.1^{\circ} \mathrm{C} / \mathrm{W}$ |
| M Package | $81.5^{\circ} \mathrm{C} / \mathrm{W}$ |

Note: The "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. The device should not be operated at these limits. The parametric values defined in the "Electrical Characteristics" table are not guaranteed at the absolute maximum ratings. The "Recommended Operating Conditions" table will define the conditions for actual device operation.

## Recommended Operating Conditions

| Symbol | Parameter | Min | Nom | Max | Units |
| :--- | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\mathrm{CC}}$ | Supply Voltage | 4.5 | 5 | 5.5 | V |

Note 1: If the select control is low, the clocks can occur simultaneously. If the select control is high, the clocks must be staggered in order to load both registers. H-high level L-low level X-irrelevant $\uparrow$-low-to-high transition
*The data output functions may be enabled or disabled by various signals at the GAB and $\bar{G} B A$ inputs. Data input functions are always enabled, i.e., data at the bus pins will be stored on every low-to-high transition on the clock inputs.

## DM74AS804B Hex 2-Input NAND Driver

## General Description

These devices contain six independent drivers, each of which performs the logic NAND function. Each driver has increased output drive capability to allow the driving of high capacitive loads.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with advanced low power Schottky TTL counterpart

National Semiconductor

## DM74AS811 Quad 2-Input Exclusive-NOR Gate with Open-Collector Outputs

## General Description

This device contains four independent gates, each of which performs the logic exclusive-NOR function. The open-collector outputs require external pull-up resistors for proper logical operation.

## Pull-Up Resistor Equations

$$
\begin{aligned}
& R_{\text {MAX }}=\frac{V_{\mathrm{CC}(\text { Min })}-V_{\mathrm{OH}}}{N_{1}\left(I_{\mathrm{OH}}\right)+N_{2}\left(I_{\mathrm{IH}}\right)} \\
& R_{\text {MIN }}=\frac{V_{\mathrm{CC}(\text { Max }}-V_{\mathrm{OL}}}{I_{\mathrm{OL}}-N_{3}\left(I_{\mathrm{IL}}\right)}
\end{aligned}
$$

Where: $\mathrm{N}_{1}\left(\mathrm{l}_{\mathrm{OH}}\right)=$ total maximum output high current for all outputs tied to pull-up resistor
$\mathrm{N}_{2}\left(\mathrm{I}_{\mathrm{IH}}\right)=$ total maximum input high current for all inputs tied to pull-up resistor
$N_{3}\left(I_{L L}\right)=$ total maximum input low current for all inputs tied to pull-up resistor

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- Functionally and pin for pin compatible with advanced low power Schottky TTL counterpart
- Improved AC performance over advanced low power Schottky counterparts
- Open collector outputs for wired AND cascading
a PNP input design reduces input loading

## DM74AS873 Dual 4-Bit D-Type Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These dual 4-bit registers feature totem-pole TRI-STATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight latches of the AS873 are transparent D-type latches meaning that while the enable $(G)$ is high the $Q$ outputs will follow the data (D) inputs. When the enable is taken low the output will be latched at the level of the data that was set up.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.

The output control does not affect the internal operation of the latches. That is, the old data can be retained or new data can be entered even while the outputs are off.
The pinout is arranged to ease printed circuit board layout. All data inputs are on one side of the package while all outputs are on the other side.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
- TRI-STATE buffer-type outputs drive bus lines directly
- Space Saving 300 Mil Wide Package
- Bus structured pinout

## DM74AS878 Dual 4-Bit D-Type Edge-Triggered Flip-Flop with Synchronous Clear

## General Description

These dual 4-bit registers feature totem-pole TRI-STATE® outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight flip-flops of the AS878 are edge-triggered D-type flip-flops. On the positive transition of the clock, the Q outputs will be set to the logic states that were set up at the D inputs.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.

The output control does not affect the internal operation of the flip-flops. That is, the old data can be retained or new data can be entered even while the outputs are off.
The pinout is arranged to ease printed circuit board layout. All data inputs are on one side of the package while all outputs are on the other side.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- TRI-STATE buffer-type outputs drive bus lines directly
- Synchronous clear
- Bus structured pinout

Connection Diagram

## Absolute Maximum Ratings

| Supply Voltage | 7 V |
| :--- | ---: |
| Input Voltage | 7 V |
| Voltage Applied to Disabled Output | 5.5 V |
| Operating Free Air Temperature Range | $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Typical $\theta_{\mathrm{JA}}$ |  |
| N Package | $47.0^{\circ} \mathrm{C} / \mathrm{W}$ |

Note: The "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. The device should not be operated at these limits. The parametric values defined in the "Electrical Characteristics" table are not guaranteed at the absolute maximum ratings. The "Recommended Operating Conditions" table will define the conditions for actual device operation.

## Recommended Operating Conditions

## DM74AS880 Dual 4-Bit D-Type <br> Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

These dual 4-bit inverting registers feature totem-pole TRISTATE outputs designed specifically for driving highly-capacitive or relatively low-impedance loads. The high-impedance state and increased high-logic-level drive provide these registers with the capability of being connected directly to and driving the bus lines in a bus-organized system without need for interface or pull-up components. They are particularly attractive for implementing buffer registers, I/O ports, bidirectional bus drivers, and working registers.
The eight inverting latches of the AS880 are transparent Dtype latches meaning that while the enable $(G)$ is high the $Q$ outputs will follow the complement of the data (D) inputs. When the enable is taken low the output will be latched at the complement of the level of the data that was set up.
A buffered output control input can be used to place the eight outputs in either a normal logic state (high or low logic levels) or a high-impedance state. In the high-impedance state the outputs neither load nor drive the bus lines significantly.

The output control does not affect the internal operation of the latches. That is, the old data can be retained or new data can be entered even while the outputs are off.
The pinout is arranged to ease printed circuit board layout. All data inputs are on one side of the package while all outputs are on the other side.

## Features

## DM74AS881B 4-Bit Arithmetic Logic Unit/Function Generator

## General Description

The DM74AS881B is an arithmetic logic unit (ALU)/function generator that has a complexity of 77 equivalent gates, respectively, on a monolithic chip. These circuits perform 16 binary arithmetic operations on two 4-bit words, as shown in Tables I and II. These operations are selected by the four function-select lines (S0, S1, S2, S3) and include addition, subtraction, decrement, and straight transfer. When performing arithmetic manipulations, the internal carries must be enabled by applying a low level voltage to the mode control input (M). A full carry look-ahead scheme is made available in these devices for fast, simultaneous carry generation by means of two cascade outputs (pins 15 and 17) for the four bits in the package. When used in conjunction with the DM74AS882 full carry look-ahead circuits, high speed arithmetic operations can be performed. The typical addition times shown previously illustrate the little additional time required for addition of longer words when full carry look-ahead is employed. The method of cascading 'AS882 circuits with these ALUs to provide multi-level full carry lookahead is illustrated under "signal designations."
If high speed is not of importance, a ripple-carry input $\left(C_{n}\right)$ and a ripple-carry output $\left(C_{n+4}\right)$ are available. However, the ripple-carry delay has also been minimized so that arithmetic manipulations for small word-lengths can be performed without external circuitry.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
© Functionally and pin-for-pin compatible with Schottky TTL counterpart
- Improved AC performance over Schottky counterpart
- Arithmetic operating modes:

Addition
Subtraction
Shift operand A one position
Magnitude comparison
Plus twelve other arithmetic operations
m Logic function modes:
Exclusive-OR
Comparator
AND, NAND, OR, NOR
Plus ten other logic operations
I Full look-ahead for high speed operations on long words

Connection Diagram

| N Package | $48.5^{\circ} \mathrm{C} / \mathrm{W}$ |

Note: The "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. The device should not be operated at these limits. The parametric values defined in the "Electrical Characteristics" table are not guaranteed at the absolute maximum ratings. The "Recommended Operating Conditions" table will define the conditions for actual device operation.

## Recommended Operating Conditions

## Functional Description

The DM74AS881B will accommodate active-high or active-low data if the pin designations are interpreted as follows:

| Pin Number | $\mathbf{2}$ | $\mathbf{1}$ | $\mathbf{2 3}$ | $\mathbf{2 2}$ | $\mathbf{2 1}$ | $\mathbf{2 0}$ | $\mathbf{1 9}$ | $\mathbf{1 8}$ | $\mathbf{9}$ | $\mathbf{1 0}$ | $\mathbf{1 1}$ | $\mathbf{1 3}$ | $\mathbf{7}$ | $\mathbf{1 6}$ | $\mathbf{1 5}$ | $\mathbf{1 7}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Active-Low Data (Table I) | $\overline{\mathrm{A} 0}$ | $\overline{\mathrm{~B}} 0$ | $\overline{\mathrm{~A}} 1$ | $\overline{\mathrm{~B}} 1$ | $\overline{\mathrm{~A}} 2$ | $\overline{\mathrm{~B}} 2$ | $\overline{\mathrm{~A}} 3$ | $\overline{\mathrm{~B}} 3$ | $\overline{\mathrm{~F}} 0$ | $\overline{\mathrm{~F}} 1$ | $\overline{\mathrm{~F}} 2$ | $\overline{\mathrm{~F}} 3$ | $\mathrm{C}_{n}$ | $\mathrm{C}_{n+4}$ | $\overline{\mathrm{P}}$ | $\overline{\mathrm{G}}$ |
| Active-High Data (Table II) | A 0 | B 0 | A 1 | B 1 | A 2 | B 2 | A 3 | B 3 | F 0 | F 1 | F 2 | F 3 | $\overline{\mathrm{C}}_{\mathrm{n}}$ | $\overline{\mathrm{C}}_{n+4}$ | X | Y |

Subtraction is accomplished by 1's complement addition where the 1 's complement of the subtrahend is generated internally. The resultant output is $A-B-1$, which requires an end-around or forced carry to provide $A-B$.
The DM74AS881B can also be utilized as a comparator. The $A=B$ output is internally decoded from the function outputs (F0, F1, F2, F3) so that when two words of equal magnitude are applied at the $A$ and $B$ inputs, it will assume a high level to indicate equality $(A=B)$. The ALU must be in the subtract mode with $\mathrm{C}_{\mathrm{n}}=\mathrm{H}$ when performing this comparison. The $\mathrm{A}=\mathrm{B}$ output is open-collector so that it can be wire-AND connected to give a comparison for more than four bits. The carry output $\left(C_{n+4}\right)$ can also be used to supply relative magnitude information. Again, the ALU must be placed in the subtract mode by placing the function-select inputs S3, S2, S1, S0 at L, H, H, L, respectively.

| Input <br> $\mathrm{C}_{\boldsymbol{n}}$ | Output <br> $\mathrm{C}_{\boldsymbol{n}+\mathbf{4}}$ | Active-Low Data <br> (Figure 1) | Active-High Data <br> (Figure 2) |
| :---: | :---: | :---: | :---: |
| H | H | $\mathrm{A} \geq \mathrm{B}$ | $\mathrm{A} \leq \mathrm{B}$ |
| H | L | $\mathrm{A}<\mathrm{B}$ | $\mathrm{A}>\mathrm{B}$ |
| L | H | $\mathrm{A}>\mathrm{B}$ | $\mathrm{A}<\mathrm{B}$ |
| L | L | $\mathrm{A} \leq \mathrm{B}$ | $\mathrm{A} \geq \mathrm{B}$ |

These circuits have been designed to not only incorporate all of the designer's requirements for arithmetic operations, but also to provide 16 possible functions of two Boolean variables without the use of external circuitry. These logic functions are selected by use of the four function-select inputs (S0, S1, S2, S3) with the mode control input (M) at a high level to disable the internal carry. The 16 logic functions are detailed in Tables I and II and include exclusiveOR, NAND, AND, NOR, and OR functions.

Functional Description (Continued)

TL/F/6336-2
FIGURE 1 (Use with Table I)

## Functional Description (Continued)

The DM74AS881B has the same pinout and same functionality as the DM74AS181B, except for the $\bar{P}, \bar{G}$, and $C_{n+4}$ outputs when the device is in the logic mode $(M=H)$.
In the logic mode, the DM74AS881B provides the user with a status check on the input words, $A$ and $B$, and the output word, $F$. While in the logic mode, the $\bar{P}, \bar{G}$ and $C_{n+4}$ outputs supply status information based upon the following logical combinations:

$$
\begin{aligned}
& \bar{P}=F 0+F 1+F 2+F 3 \\
& \bar{G}=H \\
& C_{n+4}=P C_{n} .
\end{aligned}
$$

The combination of signals on the S3 through SO control lines determines the operation performed on the data words to generate the output bits, $\mathrm{F}_{\mathrm{i}}$. By monitoring the $\overline{\mathrm{P}}$ and $\mathrm{C}_{n+4}$ outputs, the user can determine if all pairs of input bits are equal (see Function Table for Input Bits Equal/Not Equal) or if any pair of inputs is high (see Function Table for Input Pairs High/Not High). The DM74AS881B has the unique feature of providing an $A=B$ status while the exclu-sive-OR $(\oplus)$ function is being utilized. When the control inputs (S3, S2, S1, S0) equal H, L, L, H, a status check is generated to determine whether all pairs ( $A_{i}, B_{i}$ ) are equal in the following manner: $\bar{P}=(A 0 \oplus B 0)+(A 1 \oplus B 1)+(A 2$ $\oplus B 2)+(A 3 \oplus B 3)$. This unique bit-by-bit comparison of the data words, which is available on the totem pole $\overline{\mathrm{P}}$ output, is particularly useful when cascading in the DM74AS881B. As the $A=B$ condition is sensed in the first stage, the signal is propagated through the same ports used for carry generation in the arithmetic mode ( $\overline{\mathrm{P}}$ and $\overline{\mathrm{G}}$ ).

Thus, the $A=B$ status is transmitted to the second state more quickly without the need for external multiplexing logic. The $\mathrm{A}=\mathrm{B}$ open-collector output allows the user to check the validity of the bit-by-bit result by comparing the two signals for parity.
If the user wishes to check for any pair of data inputs ( $\overline{\mathrm{A}}_{\mathrm{i}}, \overline{\mathrm{B}}_{\mathrm{i}}$ ) being high, it is necessary to set the control lines (S3, S2, S1, SO) to L, H, L, L. The data pairs will then be ANDed together and the results ORed in the following manner: $\overline{\mathrm{P}}=$ $\overline{\mathrm{A}} 0 \overline{\mathrm{~B}} 0+\overline{\mathrm{A}} 1 \overline{\mathrm{~B}} 1+\overline{\mathrm{A}} 2 \overline{\mathrm{~B}} 2+\overline{\mathrm{A}} 3 \overline{\mathrm{~B}} 3$.

| S3 | S 2 | S 1 | S 0 | M | $\overline{\mathrm{P}}=\mathrm{F} 0+\mathrm{F} 1+\mathrm{F} 2+\mathrm{F} 3$ |
| :---: | :---: | :---: | :---: | :---: | :--- |
| L | H | L | L | H | $\overline{\mathrm{A}} 0 \overline{\mathrm{~B}} 0+\overline{\mathrm{A}} 1 \overline{\mathrm{~B}} 1+\overline{\mathrm{A}} 2 \overline{\mathrm{~B}} 2+\overline{\mathrm{A}} 3 \overline{\mathrm{~B}} 3$ |
| H | L | L | H | H | $(\mathrm{A} 0 \oplus \mathrm{~B} 0)+(\mathrm{A} 1 \oplus \mathrm{~B} 1)+$ <br> $(\mathrm{A} 2 \oplus \mathrm{~B} 2)+(\mathrm{A} 3 \oplus \mathrm{~B} 3)$ |

## SIGNAL DESIGNATIONS

In both Figures 1 and 2, the polarity indicators indicate that the associated input or output is active-low with respect to the function shown inside the symbol, and that the symbols are the same in both figures. The signal designations in Figure 1 agree with the indicated internal functions based on active-low data, and are for use with the logic functions and arithmetic operations shown in Table I. The signal designations have been changed in Figure 2 to accommodate the logic functions and arithmetic operations for the active-high data given in Table II. The DM74AS181 and DM74AS881B, together with the DM74AS882 and DM74S182, can be used with the signal designation of either Figure 1 or Figure 2.

Logic Diagram (Positive Logic)

## DM74AS1000A Quadruple 2-Input NAND Driver

## General Description

These devices contain four independent 2-input drivers, each of which performs the logic NAND function. The 'AS1000A is a driver version of the 'AS00. Each driver has increased output drive capability to allow the driving of high capacitive loads.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process
$\square$ Improved line receiving characteristics

## Connection Diagram

TL/F/6337-1
Order Number DM74AS1000AM or DM74AS1000AN
See NS Package Number M14A or N14A

Function Table

$$
\mathbf{Y}=\overline{\mathbf{A B}}
$$

| Inputs |  | Output |
| :---: | :---: | :---: |
| A | B | Y |
| L | L | H |
| L | H | H |
| H | L | H |
| $H$ | $H$ | L |

$H=$ High Logic Level
$L=$ Low Logic Level

## Absolute Maximum Ratings

| Supply Voltage | 7 V |
| :--- | ---: |
| Input Voltage | 7 V |
| Operating Free Air Temperature Range | $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Typical $\theta$ JA |  |
| N Package | $76.0^{\circ} \mathrm{C} / \mathrm{W}$ |
| M Package | $106.0^{\circ} \mathrm{C} / \mathrm{W}$ |

Note: The "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. The device should not be operated at these limits. The parametric values defined in the "Electrical Characteristics" table are not guaranteed at the absolute maximum ratings. The "Recommended Operating Conditions" table will define the conditions for actual device operation.

## Recommended Operating Conditions

## DM74AS1036A Quad 2-Input NOR Driver

## General Description

These devices contain four independent drivers, each of which performs the logic NOR function. Each driver has increased output drive capability, allowing the driving of high capacitive loads.

## Features

- Switching specifications at 50 pF
- Switching specification guaranteed over full temperature and $V_{C C}$ range
- Advanced oxide-isolated, ion-implanted Schottky TTL process

## Connection Diagram

Order Number DM74AS1036AM or DM74AS1036AN
See NS Package Number M14A or N14A

## Function Table

$$
\mathbf{Y}=\overline{\mathbf{A}+\mathbf{B}}
$$

| Inputs |  | Output |
| :---: | :---: | :---: |
| A | B | Y |
| L | L | H |
| X | H | L |
| H | X | L |

$\mathrm{H}=$ High Level
$\mathrm{L}=$ Low Level
$\mathrm{X}=$ Don't Care

| Absolute Maximum Ratings |  |
| :--- | ---: |
| Supply Voltage | 7 V |
| Input Voltage | 7 V |
| Operating Free Air Temperature | $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Typical $\mathrm{JJA}^{2}$ |  |
| NPackage | $76.0^{\circ} \mathrm{C} / \mathrm{W}$ |
| M Package | $106.0^{\circ} \mathrm{C} / \mathrm{W}$ |

Note: The "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. The device should not be operated at these limits. The parametric values defined in the "Electrical Characteristics" table are not guaranteed at the absolute maximum ratings. The "Recommended Operating Conditions" table will define the conditions for actual device operation.

## DM74AS1804 Hex 2-Input NAND Driver

## General Description

These devices contain six independent 2 -Input drivers each of which performs the logic NAND function. The 'AS1804 is equivalent to the 'AS804B but the supply voltage and ground pins are centered in the package. This positioning of the supply voltage and ground pins reduce the lead inductance of these pins. This reduction of lead inductance will minimize noise generated onto either the supply voltage or ground bus which is significant in high current switching applications.

## Features

- Switching specifications at 50 pF
- Switching specifications guaranteed over full temperature and $V_{C C}$ range
■ Advanced oxide-isolated, ion-implanted Schottky TTL process
- Centered $\mathrm{V}_{\mathrm{CC}}$ and GND configuration provides minimum lead inductance for high current switching applications
- High capacitive drive capability

## Connection Diagram

## DM74AS2620 Octal Bus Transceiver/MOS Driver

## General Description

These octal bus transceivers are designed to drive the capacitive input characteristics of MOS devices and allow asynchronous two-way communication between data buses. The control function implementation allows for maximum flexibility in timing.

These devices allow data transmission from the A bus to the $B$ bus or from the $B$ bus to the $A$ bus, depending upon the logic levels at the enable inputs ( $\bar{G} B A$ and GAB).
The enable inputs can be used to disable the device so that the buses are effectively isolated.
The dual enable configuration gives the 'AS2620 the capability to store data by simultaneous enabling of the $\bar{G} B A$ and GAB. Each output reinforces its input in this transceiver con-
figuration. Thus, when both control inputs are enabled and all other data sources to the two sets of bus lines are at high impedance, both sets of bus lines ( 16 in all) will remain at their last states. The 8 -bit codes appearing on the two sets of buses will be complementary.

## Features

- Bidirectional octal bus transceivers for driving MOS devices
- I/O ports have $25 \Omega$ series resistors so no external resistors are required
- Local bus-latch capability

## DM74AS2645 TRI-STATE ${ }^{\circledR}$

## Bus Transceiver/MOS Driver

## General Description

This device contains 8 pairs of logic elements configured as octal bus transceivers. They are designed to drive the capacitive input characteristics of MOS devices and allow asynchronous bidirectional communications between data buses. Data transmission from the A bus to the B bus or from the $B$ bus to the A bus are selectively controlled by (DIR and $\bar{G}$ ) the direction and enable inputs. This enable input is also used to disable the device so that the buses are effectively isolated.

## Features

m Bidirectional octal bus transceivers for driving MOS devices

- I/O ports have $25 \Omega$ series resistors so no external resistors are required
■ Advanced oxide isolated, ion-implanted Schottky TTL process
■ Switching response specified into $500 \Omega / 50 \mathrm{pF}$ load
- Switching specifications guaranteed over full temperature and $\mathrm{V}_{\mathrm{CC}}$ range

## Connection Diagram

CMOS AC Switching Test Circuits and Timing Waveforms • CMOS Application Notes • MM54HC/MM74HC MM54HCT/MM74HCT • CD4XXX • MM54CXXX/MM74CXXX • Surface Mount

## DATA ACQUISITION LINEAR DEVICES-1989

Active Filters • Analog Switches/Multiplexers • Analog-to-Digital Converters • Digital-to-Analog Converters Sample and Hold • Temperature Sensors • Voltage Regulators • Surface Mount

## DATA COMMUNICATION/LAN/UART DATABOOK—1990 <br> LAN IEEE 802.3 • High Speed Serial/IBM Data Communications • ISDN Components • UARTs Modems • Transmission Line Drivers/Receivers

## DISCRETE SEMICONDUCTOR PRODUCTS DATABOOK—1989

Selection Guide and Cross Reference Guides • Diodes • Bipolar NPN Transistors
Bipolar PNP Transistors • JFET Transistors • Surface Mount Products • Pro-Electron Series Consumer Series • Power Components • Transistor Datasheets • Process Characteristics

## DRAM MANAGEMENT HANDBOOK—1989

Dynamic Memory Control - Error Detection and Correction - Microprocessor Applications for the DP8408A/09A/17/18/19/28/29 • Microprocessor Applications for the DP8420A/21A/22A Microprocessor Applications for the NS32CG821

## EMBEDDED SYSTEM PROCESSOR DATABOOK—1989

Embedded System Processor Overview • Central Processing Units • Slave Processors • Peripherals Development Systems and Software Tools

## F100K DATABOOK—1989

Family Overview • F100K Datasheets • 11C Datasheets•10K and 100K Memory Datasheets Design Guide • Circuit Basics • Logic Design • Transmission Line Concepts • System Considerations Power Distribution and Thermal Considerations • Testing Techniques • Quality Assurance and Reliability

FACTTM ADVANCED CMOS LOGIC DATABOOK—1989<br>Description and Family Characteristics • Ratings, Specifications and Waveforms<br>Design Considerations • 54AC/74ACXXX • 54ACT/74ACTXXX

FAST® ADVANCED SCHOTTKY TTL LOGIC DATABOOK—Rev. 1-1988<br>Circuit Characteristics • Ratings, Specifications and Waveforms • Design Considerations • 54F/74FXXX

## FAST ${ }^{\circledR}$ APPLICATIONS HANDBOOK—REPRINT

Reprint of 1987 Fairchild FAST Applications Handbook
Contains application information on the FAST family: Introduction • Multiplexers • Decoders • Encoders
Operators • FIFOs • Counters • TTL Small Scale Integration • Line Driving and System Design
FAST Characteristics and Testing • Packaging Characteristics • Index

## GENERAL PURPOSE LINEAR DEVICES DATABOOK—1989

Continuous Voltage Regulators • Switching Voltage Regulators • Operational Amplifiers • Buffers • Voltage Comparators Instrumentation Amplifiers • Surface Mount

## GRAPHICS HANDBOOK—1989

Advanced Graphics Chipset • DP8500 Development Tools • Application Notes

## INTERFACE DATABOOK—1988

Transmission Line Drivers/Receivers • Bus Transceivers • Peripheral Power Drivers • Display Drivers Memory Support • Microprocessor Support • Level Translators and Buffers • Frequency Synthesis • Hi-Rel Interface

## LINEAR APPLICATIONS HANDBOOK-1986

The purpose of this handbook is to provide a fully indexed and cross-referenced collection of linear integrated circuit applications using both monolithic and hybrid circuits from National Semiconductor.
Individual application notes are normally written to explain the operation and use of one particular device or to detail various methods of accomplishing a given function. The organization of this handbook takes advantage of this innate coherence by keeping each application note intact, arranging them in numerical order, and providing a detailed Subject Index.

## LS/S/TTL DATABOOK—1989

Contains former Fairchild Products
Introduction to Bipolar Logic • Low Power Schottky • Schottky • TTL • TTL—Low Power

## MASS STORAGE HANDBOOK—1989

Rigid Disk Pulse Detectors • Rigid Disk Data Separators/Synchronizers and ENDECs
Rigid Disk Data Controller • SCSI Bus Interface Circuits • Floppy Disk Controllers • Disk Drive Interface Circuits
Rigid Disk Preamplifiers and Servo Control Circuits • Rigid Disk Microcontroller Circuits • Disk Interface Design Guide

## MEMORY DATABOOK-1990

PROMs, EPROMs, EEPROMs • TTL I/O SRAMs • ECL I/O SRAMs

## MICROCONTROLLER DATABOOK—1989

COP400 Family • COP800 Family • COPS Applications • HPC Family • HPC Applications MICROWIRE and MICROWIRE/PLUS Peripherals • Microcontroller Development Tools

## MICROPROCESSOR DATABOOK—1989

Series 32000 Overview • Central Processing Units • Slave Processors • Peripherals
Development Systems and Software Tools • Application Notes • NSC800 Family

## RELIABILITY HANDBOOK—1986

Reliability and the Die • Internal Construction • Finished Package • MIL-STD-883 • MIL-M-38510
The Specification Development Process • Reliability and the Hybrid Device • VLSI/VHSIC Devices
Radiation Environment • Electrostatic Discharge • Discrete Device • Standardization Quality Assurance and Reliability Engineering • Reliability and Documentation • Commercial Grade Device European Reliability Programs • Reliability and the Cost of Semiconductor Ownership Reliability Testing at National Semiconductor • The Total Military/Aerospace Standardization Program 883B/RETSTM Products • MILS/RETSTM Products • 883/RETSTM Hybrids • MIL-M-38510 Class B Products Radiation Hardened Technology • Wafer Fabrication • Semiconductor Assembly and Packaging Semiconductor Packages • Glossary of Terms • Key Government Agencies • AN/ Numbers and Acronyms Bibliography • MIL-M-38510 and DESC Drawing Cross Listing

## SPECIAL PURPOSE LINEAR DEVICES DATABOOK—1989

Audio Circuits • Radio Circuits • Video Circuits • Motion Control Circuits • Special Function Circuits Surface Mount

## TELECOMMUNICATIONS—1987

Line Card Components • Integrated Services Digital Network Components • Modems Analog Telephone Components • Application Notes

[^8]:    Note 1: See Section 1 for test waveforms and output load.

[^9]:    Note 1: See Section 1 for test waveforms and output load.

[^10]:    $H=$ High Logic Level
    L = Low Logic Level

[^11]:    $H=$ High Logic Level
    L = Low Logic Levei
    $X=$ Either Low or High Logic Level

[^12]:    Note 1: See Section 1 for test waveforms and output load.

[^13]:    This document contains information on a product under development. National Semiconductor Corporation reserves the right to change or discontinue this

[^14]:    $\mathrm{L}=$ Low State, $\mathrm{H}=$ High State, $\mathrm{X}=$ Don't Care

[^15]:    Note 1: The symbol ( $\uparrow$ ) indicates that the rising edge of the clock is used as a reference.

[^16]:    $\mathrm{H}=$ high level (steady-state), $\mathrm{L}=$ low level (steady-state).
    $X=$ don't care (any input, including transitions).
    $\uparrow=$ transition from low-to-high level.
    a...h $=$ the level of steady-state input at inputs $A$ through $H$, respectively.
    $Q_{A 0}, Q_{B O}, Q_{H O}=$ the level of $Q_{A}, Q_{B}$, or $Q_{H}$, respectively, before the indicated steady state input conditions were established.
    $\mathrm{Q}_{\mathrm{An}}, \mathrm{Q}_{\mathrm{Gn}}=$ the level of $\mathrm{Q}_{\mathrm{A}}$ or $\mathrm{Q}_{\mathrm{G}}$, respectively, before the most recent $\uparrow$ transition of the clock.

[^17]:    $H=$ High Level, $L=$ Low Level, X = Don't Care
    Z = High Impedance (off)

[^18]:    Select inputs $A$ and $B$ are common to both sections
    $\mathrm{H}=$ High Level, $\mathrm{L}=$ Low Level, $\mathrm{X}=$ Don't Care

[^19]:    $\mathrm{L}=$ Low State, $\mathrm{H}=$ High State, $\mathrm{X}=$ Don't Care
    $\uparrow=$ Positive Edge Transition
    Z = High Impedance State
    $\mathrm{Q}_{0}=$ Previous Condition of Q

[^20]:    $L=$ Low Logic Level
    $H=$ High Logic Level
    $X=$ Either Low or High Logic Level

[^21]:    Note 2: For I/O ports, $I_{I H}$ and $I_{I L}$ parameters include the TRI-STATE ${ }^{\text {© }}$ output current ( $l_{\text {OZL }}$ and $I_{\text {OZH }}$ ).

[^22]:    Note 1: For I/O ports the TRI-STATE output currents ( $\mathrm{I}_{\mathrm{OZH}}$ and $\mathrm{I}_{\mathrm{OZV}}$ ) are included in the $\mathrm{I}_{\mathrm{IH}}$ and $\mathrm{I}_{\mathrm{I}}$ parameters.

[^23]:    Note 1: For I/O ports the TRI-STATE output currents ( $\mathrm{l}_{\mathrm{OZH}}$ and $\mathrm{I}_{\mathrm{OZU}}$ ) are included in the $\mathrm{I}_{\mathrm{IH}}$ and $\mathrm{I}_{\mathrm{IL}}$ parameters.

[^24]:    $H=$ High Logic Level
    L = Low Logic Level

[^25]:    Note 1: See Section 1 for test waveforms and output load.

[^26]:    L = Low State, $H=$ High State, $X=$ Don't Care
    $Z=$ High Impedance State
    $\overline{\mathrm{Q}}_{0}=$ Previous Condition of $\overline{\mathrm{Q}}$

[^27]:    H = High Logic Level
    $L=$ Low Logic Level

[^28]:    Note 1: See Section 1 for test waveforms and output load.

[^29]:    Note 1: See Section 1 for test waveforms and output load.

[^30]:    $\mathrm{L}=$ Low Logic Level
    $H=$ High Logic Level
    $X=$ Either Low or High Logic Level

[^31]:    $\mathrm{L}=$ Low Logic Level
    $H=$ High Logic Level
    $X=$ Either Low or High Logic Level

[^32]:    Note 1: See Section 1 for test waveforms and output load.

[^33]:    L = Low Logic Level
    $H=$ High Logic Level

[^34]:    Note 1: See Section 1 for test waveforms and output load.

[^35]:    $L=$ Low Logic Level, $H=$ High Logic Level
    X = Don't Care (Either Low or High Logic Level)

[^36]:    H = High Logic Level
    L = Low Logic Level

[^37]:    Note 1: See Section 1 for test waveforms and output load.

[^38]:    Note 1: See Section 1 for test waveforms and output load.

[^39]:    $H=$ High Level, $L=$ Low Level, $X=$ Don't Care

[^40]:    $H=$ High Logic State
    $L=$ Low Logic State
    $Q_{0}=$ The level of $Q$ before the indicated steady-state input conditions were established.
    $\uparrow=$ Transition from Low Logic Level to High Logic Leve!

[^41]:    *Contact your local NSC representative about surface mount (M) package availability.

[^42]:    - Contact your local NSC representative about surface mount (M) package availability.

[^43]:    Note: The output conditions have been chosen to produce a current that closely approximates one half the true short-circuit output current, los.

[^44]:    L = Low Logic Level
    H = High Logic Level

[^45]:    H = High Level, $L=$ Low Level, $X=$ Don't Care
