## LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

National Semiconductor Corporation 2900 Semiconductor Drive, P.O. Box 58090, Santa Clara, California 95052-8090 (408) 721-5000 TWX (910) 339-9240
National does not assume any responsibility for use of any circuitry described, no circuit patent licenses are implied, and National reserves the right, at any time without notice, to change said circuitry or specifications.

## Introduction

FACTTM (Fairchild Advanced CMOS Technology) is a very high-speed, low power CMOS Logic family utilizing a $1.3 \mu \mathrm{M}$ Isoplanar silicon gate CMOS process. FACT logic functions can attain speeds similar to that of Advanced Low Power Schottky while retaining the advantages of CMOS logic: Ultra low static power and high noise immunity. FACT offers the system designer the added benefit of superior line driving characteristics and excellent ESD and Latch-up immunity.
FACT Quiet Series, an extension of the FACT family, is a high speed, low power CMOS family IDEAL for ACMOS applications requiring increased noise margins. Utilizing NSC Quiet Series Technology, FACT QS features GTOTM outputs control, undershoot corrector and a split ground bus for superior ACMOS performance. In addition, FACT QS features improved AC specifications, specifies maximum pin-to-pin output skew and provides enhanced ESD immunity and latch-up protection.
FACT FCT, an extension of the FACT family, features 7 ns propagation delays and $64 / 48 \mathrm{~mA}$ output drive. The series incorporates National's Quiet Series Technology to provide the lowest noise performance of any FCT logic family. FACT FCTA is the high speed, high drive extension of the FACT family featuring 5 ns maximum propagation delays and 64/48 mA output drive. In addition, FACT FCTA features quiet circuitry to provide increased noise margins.
The FACT/FACT QS families consist of devices in two categories:

1. AC/ACQ-standard logic functions with CMOS compatible inputs and TTL and MOS compatible outputs;
2. ACT/ACTQ-standard logic functions with TTL compatible inputs and TTL and MOS compatible outputs.

## Product Index and Selection Guide

Lists FACT, FACT QS, FACT FCT, and FACT FCTA circuits currently available, in design or planned. The selection guide groups the circuits by function.

## Section 1 Descriptions and Family Characteristics

Basic information on FACT performance including technologies.

## Section 2 Ratings, Specifications and Waveforms 2-1

Contains common ratings and specifications for FACT devices, as well as AC test loads and waveforms.

Section 3 Design Considerations ......... 3-1
Information to assist both TTL and CMOS designers to get the most out of the FACT family.

Section 4 Advanced CMOS Datasheets ..4-1 Contains datasheets for currently available and pending new FACT products.

## Section 5 Quiet Series Datasheets. <br> 5-1

Contains datasheets for currently available and pending new FACT Quiet Series products.

Section 6 FCT Series Datasheets . . . . . . . 6-1
Contains datasheets for currently available and pending new FACT FCT products.

Section 7 FCT A and B Series Datasheets 7-1
Contains datasheets for currently available and pending new FACT FCTA products.

## Section 8 Ordering Information and Physical Dimensions <br> 8-1

## Definition of Terms

## Product Status Definitions

| Data Sheet Identification | Product Status | Definition |
| :--- | :--- | :--- |
| Advance Information | Formative or <br> In Design | This data sheet contains the design specifications for product <br> development. Specifications may change in any manner without notice. |
| Preliminary | First <br> Production | This data sheet contains preliminary data, and supplementary data will <br> be published at a later date. National Semiconductor Corporation <br> reserves the right to make changes at any time without notice in order <br> to improve design and supply the best possible product. |
| No <br> Identification <br> Noted | Full <br> Production <br> Corporation reserves the right to make chantains final specifications. National Semiconductor any time without <br> notice in order to improve design and supply the best possible product. |  |

National Semiconductor Corporation reserves the right to make changes without further notice to any products herein to improve reliability, function or design. National does not assume any liability arising out of the application or use of any product or circuit described herein; neither does it convey any license under its patent rights, nor the rights of others.

## Alpha-Numeric Index

54AC/74AC00 Quad 2-Input NAND Gate ..... 4-5
54AC/74AC02 Quad 2-Input NOR Gate ..... 4-9
54AC/74AC04 Hex Inverter ..... 4-13
54AC/74AC08 Quad 2-Input AND Gate ..... 4-17
54AC/74AC10 Triple 3-Input NAND Gate ..... 4-21
54AC/74AC11 Triple 3-Input AND Gate ..... 4-25
54AC/74AC14 Hex Inverter with Schmitt Trigger Input ..... 4-28
54AC/74AC20 Dual 4-Input NAND Gate ..... 4-31
54AC/74AC32 Quad 2-Input OR Gate ..... 4-34
54AC/74AC74 Dual D Positive Edge-Triggered Flip-Flop ..... 4-38
54AC/74AC86 Quad 2-Input Exclusive-OR Gate ..... 4-44
54AC/74AC109 Dual JK Positive Edge-Triggered Flip-Flop ..... $4-47$
54AC/74AC125 Quad TRI-STATE Buffer ..... 4-53
54AC/74AC138 1-of-8 Decoder/Demultiplexer ..... 4-57
54AC/74AC139 Dual 1-of-4 Decoder/Demultiplexer ..... 4-63
54AC/74AC151 8-Input Multiplexer ..... 4-68
54AC/74AC153 Dual 4-Input Multiplexer ..... 4-74
54AC/74AC157 Quad 2-Input Multiplexer ..... 4-79
54AC/74AC158 Quad 2-Input Multiplexer ..... 4-84
54AC/74AC161 Synchronous Presettable Binary Counter ..... 4-89
54AC/74AC163 Synchronous Presettable Binary Counter ..... 4-97
54AC/74AC169 4-Stage Synchronous Bidirectional Counter ..... 4-105
54AC/74AC174 Hex D Flip-Flop with Master Reset ..... 4-113
54AC/74AC175 Quad D Flip-Flop ..... 4-119
54AC/74AC191 Up/Down Counter with Preset and Ripple Clock ..... 4-125
54AC/74AC240 Octal Buffer/Line Driver with TRI-STATE Outputs ..... 4-132
54AC/74AC241 Octal Buffer/Line Driver with TRI-STATE Outputs ..... 4-136
54AC/74AC244 Octal Buffer/Line Driver with TRI-STATE Outputs ..... 4-140
54AC/74AC245 Octal Bidirectional Transceiver with TRI-STATE Inputs/Outputs ..... 4-144
54AC/74AC251 8-Input Multiplexer with TRI-STATE Output ..... 4-148
54AC/74AC253 Dual 4-Input Multiplexer with TRI-STATE Outputs ..... 4-154
54AC/74AC257 Quad 2-Input Multiplexer with TRI-STATE Outputs ..... 4-160
54AC/74AC258 Quad 2-Input Multiplexer with TRI-STATE Outputs ..... 4-165
54AC/74AC273 Octal D Flip-Flop ..... 4-170
54AC/74AC280 9-Bit Parity Generator/Checker ..... 4-175
54AC/74AC299 8-Input Universal Shift/Storage Register with Common Parallel I/O Pins ..... 4-179
54AC/74AC367 Hex TRI-STATE Buffer ..... 4-191
54AC/74AC373 Octal Transparent Latch with TRI-STATE Outputs ..... 4-197
54AC/74AC374 Octal D Flip-Flop with TRI-STATE Outputs ..... 4-203
54AC/74AC377 Octal D Flip-Flop with Clock Enable ..... 4-209
54AC/74AC378 Parallel D Register with Enable ..... 4-215
54AC/74AC520 8-Bit Identity Comparator ..... 4-223
54AC/74AC521 8-Bit Identity Comparator ..... 4-229
54AC/74AC540 Octal Buffer/Line Driver with TRI-STATE Outputs ..... 4-240
54AC/74AC541 Octal Buffer/Line Driver with TRI-STATE Outputs ..... 4-243
54AC/74AC574 Octal D Flip-Flop with TRI-STATE Outputs ..... 4-259
54AC/74AC646 Octal Transceiver/Register with TRI-STATE Outputs ..... 4-265
54AC/74AC648 Octal Transceiver/Register with TRI-STATE Outputs ..... 4-272
54AC/74AC821 10-Bit D Flip-Flop with TRI-STATE Outputs ..... 4-294
54AC/74AC843 9-Bit Transparent Latch ..... 4-313
54AC/74AC899 9-Bit Latchable Transceiver Register with Parity Generator/Checker ..... 4-326

## Alpha-Numeric Index ${ }_{\text {(Conitiues) }}$

54AC/74AC2525 Minimum Skew Clock Driver ..... 4-338
54AC/74AC2526 Minimum Skew Clock Driver with Multiplexed Clock Input ..... 4-338
54AC/74AC2708 $64 \times 9$ First-In, First-Out Memory ..... 4-339
54ACQ/74ACQ240 Quiet Series Octal Buffer/Line Driver with TRI-STATE Outputs ..... 5-7
54ACQ/74ACQ241 Quiet Series Octal Buffer/Line Driver with TRI-STATE Outputs ..... 5-12
54ACQ/74ACQ244 Quiet Series Octal Buffer/Line Driver with TRI-STATE Outputs ..... 5-17
54ACQ/74ACQ245 Quiet Series Octal Bidirectional Transceiver with TRI STATE Outputs ..... 5-22
54ACQ/74ACQ273 Quiet Series Octal D Flip-Flop ..... 5-27
54ACQ/74ACQ373 Quiet Series Octal Transparent Latch with TRI-STATE Outputs ..... 5-32
54ACQ/74ACQ374 Quiet Series Octal D Flip-Flop with TRI-STATE Outputs ..... 5-38
54ACQ/74ACQ377 Quiet Series Octal D Flip-Flop with Clock Enable ..... 5-44
54ACQ/74ACQ533 Quiet Series Octal Latch with TRI-STATE Outputs ..... 5-45
54ACQ/74ACQ534 Quiet Series Octal D Flip-Flop with TRI-STATE Outputs ..... 5-51
54ACQ/74ACQ543 Quiet Series Octal Registered Transceiver with TRI-STATE Outputs ..... 5-57
54ACQ/74ACQ544 Quiet Series Octal Registered Transceiver with TRI-STATE Outputs ..... 5-58
54ACQ/74ACQ563 Quiet Series Octal Latch with TRI-STATE Outputs ..... 5-59
54ACQ/74ACQ564 Quiet Series Octal D Flip-Flop with TRI-STATE Outputs ..... 5-66
54ACQ/74ACQ573 Quiet Series Octal Latch with TRI-STATE Outputs ..... 5-72
54ACQ/74ACQ574 Quiet Series Octal D Flip-Flop with TRI-STATE Outputs ..... 5-78
54ACQ/74ACQ821 Quiet Series 10-Bit D Flip-Flop with TRI-STATE Outputs ..... 5-87
54ACT/74ACT00 Quad 2-Input NAND Gate ..... 4-5
54ACT/74ACT02 Quad 2-Input NOR Gate ..... 4-9
54ACT/74ACT04 Hex Inverter ..... 4-13

54FCT/74FCT574A Octal D Flip-Flop with TRI-STATE Outputs ..... 7-67
54FCT/74FCT646 Octal Transceiver/Register with TRI-STATE Outputs ..... 6-80
54FCT/74FCT646A Octal Transceiver/Register with TRI-STATE Outputs ..... 7-72
54FCT/74FCT821A 10-Bit D Flip-Flop with TRI-STATE Outputs ..... 7-73
54FCT/74FCT821B 10-Bit D Flip-Flop with TRI-STATE Outputs ..... 7-73
54FCT/74FCT823A 9-Bit D Flip-Flop with TRI-STATE Outputs ..... 7-74
54FCT/74FCT823B 9-Bit D Flip-Flop with TRI-STATE Outputs ..... 7-74
54FCT/74FCT825A 9-Bit D Flip-Flop with TRI-STATE Outputs ..... 7-75
54FCT/74FCT825B 9-Bit D Flip-Flop with TRI-STATE Outputs ..... 7-75
54FCT/74FCT827A 10-Bit Buffer/Line Driver with TRI-STATE Outputs ..... 7-76
54FCT/74FCT827B 10-Bit Buffer/Line Driver with TRI-STATE Outputs ..... 7-76
54FCT/74FCT841A 10-Bit Transparent Latch with TRI-STATE Outputs ..... 7-77
54FCT/74FCT841B 10-Bit Transparent Latch with TRI-STATE Outputs ..... 7-77
54FCT/74FCT843A 9-Bit Transparent Latch with TRI-STATE Outputs . ..... 7-78
54FCT/74FCT843B 9-Bit Transparent Latch with TRI-STATE Outputs ..... 7-78
54FCT/74FCT845A 8-Bit Transparent Latch with TRI-STATE Outputs . ..... 7-79

## Alpha-Numeric Index ${ }_{\text {(Coninued) }}$

54FCT/74FCT845B 8-Bit Transparent Latch with TRI-STATE Outputs ..... 7-79
54FCT/74FCT899A 9-Bit Latchable Transceiver with Parity Generator/Checker ..... 7-80
LM1882 Programmable Video Sync Generator ..... 4-279

## FACT $^{\text {TM }}$ Selection Guide

## Gates

| Function | Device |
| :--- | :--- |
| NAND |  |
| Quad 2-Input | $54 \mathrm{AC} / 74 \mathrm{ACO0}$ |
| Quad 2-Input | $54 \mathrm{ACT} / 74 \mathrm{ACT00}$ |
| Triple 3-Input | $54 \mathrm{AC} / 74 \mathrm{AC} 10$ |
| Triple 3-Input | $54 \mathrm{ACT} / 74 \mathrm{ACT} 10$ |
| Dual 4-Input | $54 \mathrm{AC} / 74 \mathrm{AC} 20$ |
| AND |  |
| Quad 2-Input | $54 \mathrm{AC/74AC08}$ |
| Quad 2-Input | $54 \mathrm{ACT} / 74 \mathrm{ACT08}$ |
| Triple 3-Input | $54 \mathrm{AC} / 74 \mathrm{AC} 11$ |
| OR/NOR/Exclusive-OR |  |
| Quad 2-Input OR | $54 \mathrm{AC} / 74 \mathrm{AC32}$ |
| Quad 2-Input OR | $54 \mathrm{ACT} / 74 \mathrm{ACT32}$ |
| Quad 2-Input NOR | $54 \mathrm{AC} / 74 \mathrm{ACO2}$ |
| Quad 2-Input NOR | $54 \mathrm{ACT} / 74 \mathrm{ACT02}$ |
| Quad 2-Input Exclusive-OR | $54 \mathrm{AC} / 74 \mathrm{AC86}$ |
| Inverter |  |
| Hex Inverter | $54 \mathrm{AC} / 74 \mathrm{ACO4}$ |
| Hex Inverter | $54 \mathrm{ACT} / 74 \mathrm{ACT04}$ |
| Hex Schmitt Trigger Inverter | $54 \mathrm{AC} / 74 \mathrm{AC} 14$ |

## Registers

| Function | Device | Clock <br> Inputs |
| :--- | :---: | :---: |
| Parallel D Register w/Enable | 54AC/74AC378 | No |
| Quad 2-Port Register | $54 \mathrm{ACT} / 74 \mathrm{ACT399}$ | $1(-)$ |
| Diagnostic and Pipeline Register | $54 \mathrm{ACT} / 74 \mathrm{ACT} 818$ | 2 |

## Parity Generator/Checkers

| Function | Device |
| :---: | :---: |
| Parity Generator/Checker | 54AC/74AC280 |
| Octal Bidirectional Bus Transceiver <br> w/Parity Generator/Checker | 54ACTQ/74ACTQ657 |
| Octal Bidirectional Bus Transceiver <br> w/Parity Generator/Checker | 54FCT/74FCT657 |
| 9-Bit Registered Transceiver <br> w/Parity Generator/Checker | 54AC/74AC899 |
| 9-Bit Registered Transceiver <br> w/Parity Generator/Checker | 54ACT/74ACT899 |
| 9-Bit Registered Transceiver <br> w/Parity Generator/Checker | 54FCT/74FCT899 |

National Semiconductor

# FACT ${ }^{\text {TM }}$ Descriptions and Family Characteristics 

## National Semiconductor Advanced CMOS Technology-FACT-Logic

Fairchild Semiconductor introduced FACT (Fairchild Advanced CMOS Technology) logic, a family of high speed advanced CMOS circuits, in 1985.
FACT logic offers a unique combination of high speed, low power dissipation, high noise immunity, wide fanout capability, extended power supply range and high reliability.
This data book describes the product line with device specifications as well as material discussing design considerations and comparing the FACT family to predecessor technologies.
The 1.3-micron silicon gate CMOS process utilized in this family has been proven in the field of high performance gate arrays, CMOS ASIC, and FACT. It has been further enhanced to meet and exceed the JEDEC standards for 74ACXX logic.
In 1989, National Semiconductor introduced the FACT Quiet Series ${ }^{\text {TM }}$ product line. This line of mostly octal bus-oriented logic functions is an enhancement of the original FACT line. Manufactured on a sub-micron silicon gate CMOS process, the FACT QS devices offer the lowest noise characteristics of any Advanced CMOS process with AC performance that is faster than FACT.

Also in 1989, National Semiconductor introduced its offering of fast CMOS technology or FACT FCT/FCTA. These product lines offer the fastest speeds of any TTL or CMOS logic, high DC output current drive, as well as the low noise design innovations of FACT QS.
For direct replacement of LS, ALS and other TTL devices, the 'ACT, 'ACTQ, 'FCT and 'FCTA circuits with TTL-type input thresholds are included in the FACT family.

## Characteristics

- Full Logic Product Line
- Industry Standard Functions and Pinouts for SSI, MSI and LSI
- Meets or Exceeds JEDEC Standards for 74ACXX Family
- TTL Inputs on Selected Circuits
- High Performance Outputs
- Common Output Structure for Standard Gates and Buffer/Drivers
- Output Sink/Source Current of 24 mA on AC/ACT and ACQ/ACTQ
- Output Sink/Source Current of $48 / 64 \mathrm{~mA}$ on FCT/FCTA
- Transmission Line Driving $50 \Omega$ (Commercial)/75 $\Omega$ (Military) Guaranteed
- Operation from $2 \mathrm{~V}-6 \mathrm{~V} \mathrm{~V}_{\mathrm{DD}}$ Guaranteed ('AC/'ACQ)

』. Temperature Range

- Commercial $\quad-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
- Military
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
$\square$ Improved ESD Protection Network
- High Current Latch-Up Immunity
@ Patented Noise Suppression Circuitry on ACQ/ACTQ and FCT/FCTA

## Interfacing

FACT devices have a wide operating voltage range ( $V_{D D}=$ $2 V_{D C}$ to $6 V_{D C}$, 'AC/'ACQ) and sufficient current drive to interface with most other logic families available today.
Device designators are as follows:
'AC/'ACQ - These are high speed CMOS devices with CMOS input switching levels and buffered CMOS outputs that can drive $\pm 24 \mathrm{~mA}$ of $\mathrm{I}_{\mathrm{OH}}$ and $\mathrm{I}_{\mathrm{OL}}$ current. Industry standard 'AC/ 'ACQ nomenclature and pinouts are used.
'ACT/'ACTQ - These are high speed CMOS devices with a 'FCT/'FCTA TTL-to-CMOS input buffer stage. These device inputs are designed to interface with TTL outputs operating with a $V_{D D}=5 \mathrm{~V}$ $\pm 0.5 \mathrm{~V}$ with $\mathrm{V}_{\mathrm{OH}}=2.4 \mathrm{~V}$ and $\mathrm{V}_{\mathrm{OL}}=0.4 \mathrm{~V}$, but are functional over the entire FACT operating voltage range of $2.0 \mathrm{~V}_{\mathrm{DC}}$ to 5.5 $V_{D C}$. These devices have buffered outputs that will drive CMOS or TTL devices with no additional interface circuitry. 'ACT/'ACTQ devices have the same output structures as 'AC/'ACQ devices. 'FCT/'FCTA can drive +64 mA of $\mathrm{I}_{\mathrm{OL}}$ and -15 mA of $\mathrm{I}_{\mathrm{OH}}$ current.

## Low Power CMOS Operation

If there is one single characteristic that justifies the existence of CMOS, it is low power dissipation. In the quiescent state, FACT draws 1000 times less power than the equivalent LS or ALS TTL device. This enhances system reliability; because costly regulated high current power supplies, heat sinks and fans are eliminated, FACT logic devices are ideal for portable systems such as laptop computers and backpack communications systems. Operating power is also very low for FACT logic. Power consumption of various technologies with a clock frequency of 1 MHz is shown below.

$$
\begin{aligned}
\text { FACT } & =0.1 \mathrm{~mW} / \text { Gate } \\
\text { ALS } & =1.2 \mathrm{~mW} / \text { Gate } \\
\mathrm{LS} & =2.0 \mathrm{~mW} / \text { Gate } \\
\mathrm{HC} & =0.1 \mathrm{~mW} / \text { Gate }
\end{aligned}
$$

## Low Power CMOS Operation (Continued)

<br>TL/F/10158-1

FIGURE 1-1. IDD vs VDD
Figure 1-1 illustrates the effects of IDD versus power supply voltage ( $\mathrm{V}_{\mathrm{DD}}$ ) for two load capacitance values: 50 pF and stray capacitance. The clock frequency was 1 MHz for the measurements.

## AC Performance

In comparison to LS, ALS and HC families, FACT devices have faster internal gate delays as well as the basic gate delays. Additionally, as the level of integration increases, FACT logic leads the way to very high-speed systems.
The examples below describe typical values for a $74 \times \times 138$, 3-to-8 line decoder and a 74xx244 line driver.

```
'138
FACT AC = 6.0 ns @ C C = 50 pF
ALS = 12.0 ns @ C C = 50 pF
LS = 22.0 ns @ C C = 15 pF
HC = 17.5 ns @ C C = 50 pF
```

| '244 |  |
| :--- | :--- |
| FACT FCTA | $=3.0 \mathrm{~ns} @ C_{L}=50 \mathrm{pF}$ |
| FACT ACQ | $=4.0 \mathrm{~ns} @ \mathrm{C}_{\mathrm{L}}=50 \mathrm{pF}$ |
| FACT AC | $=5.0 \mathrm{~ns} @ C_{\mathrm{L}}=50 \mathrm{pF}$ |
| ALS | $=7.0 \mathrm{~ns} @ C_{L}=50 \mathrm{pF}$ |
| LS | $=1.0 \mathrm{~ns} @ \mathrm{C}_{\mathrm{L}}=45 \mathrm{pF}$ |
| HC | $=14.0 \mathrm{~ns} @ C_{L}=50 \mathrm{pF}$ |

AC performance specifications are guaranteed at 5.0 V $\pm 0.5 \mathrm{~V}$ and $3.3 \mathrm{~V} \pm 0.3 \mathrm{~V}$. For worst case design at $2.0 \mathrm{~V} \mathrm{~V}_{\mathrm{DD}}$ on all device types, the formula below can be used to determine AC performance.
AC performance at $2.0 \mathrm{~V} \mathrm{~V}_{\mathrm{DD}}=1.9 \times \mathrm{AC}$ specification at 3.3V.

## Multiple Output Switching

Propagation delay is affected by the number of outputs switching simultaneously. Typically, devices with more than one output will follow the rule: for each output switching, derate the databook specification by 250 ps. This effect typically is not significant on an octal device unless more than four outputs are switching simultaneously. This derating is valid for the entire temperature range and $5.0 \mathrm{~V} \pm 10 \% \mathrm{~V}_{\mathrm{DD}}$.

## Noise Immunity

The DC noise immunity of a logic family is also an important equipment cost factor in terms of decoupling components, power supply dynamic resistance and regulation as well as layout rules for PC boards and signal cables.
The comparisons shown describe the difference between the input threshold of a device and the output voltage, $\left|V_{I L}-V_{O L}\right| /\left|V_{I H}-V_{O H}\right|$ at $4.5 \mathrm{~V} V_{D D}$.

$$
\begin{array}{ll}
\mathrm{FACT} & =1.25 \mathrm{~V} / 1.25 \mathrm{~V} \\
\mathrm{ALS} & =0.4 \mathrm{~V} / 0.7 \mathrm{~V} \\
\mathrm{LS} & =0.3 \mathrm{~V} / 0.7 \mathrm{~V} @ 4.75 \mathrm{~V} \mathrm{~V}_{\mathrm{DD}} \\
\mathrm{HC} & =0.8 \mathrm{~V} / 1.25 \mathrm{~V}
\end{array}
$$

## Dynamic Output Drive

Traditionally, in order to predict what incident wave voltages would occur in a system, the designer was required to do an output analysis using a Bergeron diagram. Not only is this a long and time consuming operation, but the designer needed to depend upon the accuracy and reliability of the manu-facturer-supplied "typical" output I/V curve. Additionally, there was no way to guarantee that any supplied device would meet these "typical" performance values across the operating voltage and temperature limits. Fortunately for the system designers, FACT has taken the necessary steps to guarantee incident wave switching on transmission lines with impedances as low as $50 \Omega$ for the commercial temperature range and $75 \Omega$ for the military temperature range.
Figure 1-2 shows a Bergeron diagram for switching both HIGH-to-LOW and LOW-to-HIGH. On the right side of the graph (lout $>0$ ), are the $\mathrm{V}_{\mathrm{OH}}$ and $\mathrm{I}_{\mathrm{IH}}$ curves for FACT logic while on the left side (lout < 0), are the curves for $\mathrm{V}_{\mathrm{OL}}$ and IIL. Although we will only discuss here the LOW-to-HIGH transition, the information presented may be applied to a HIGH-to-LOW transition.

Dynamic Output Drive (Continued)

FIGURE 1-2. Gate Driving $50 \Omega$ Line Reflection Diagram
Begin analysis at the $\mathrm{V}_{\mathrm{OL}}$ (quiescent) point. This is the intersection of the $\mathrm{V}_{\mathrm{OL}} / \mathrm{l}_{\mathrm{OL}}$ curve for the output and the $\mathrm{V}_{\text {IN }} / \mathrm{I}_{\mathrm{IN}}$ curve for the input. For CMOS inputs and outputs, this point will be approximately 100 mV . Then draw a $50 \Omega$ load line from this intersection to the $\mathrm{VOH}_{\mathrm{OH}} / \mathrm{IOH}_{\mathrm{OH}}$ curve as shown by Line 1. This intersection is the voltage that the incident wave will have. Here it occurs at approximately 3.95 V . Then draw a line with a slope of $-50 \Omega$ from this first intersection point to the $V_{\mathbb{N}} / I_{\mathbb{N}}$ curve as shown by Line 2 . This second intersection will be the first reflection back from the input gate. Continue this process of drawing the load lines from each intersection to the next. Lines terminating on the $\mathrm{VOH}_{\mathrm{OH}} / \mathrm{IOH}_{\mathrm{O}}$ curve should have positive slopes while lines terminating on the $\mathrm{V}_{\mathbb{N}} / I_{\mathbb{N}}$ curve should have negative slopes. Each intersection point predicts the voltage of each reflected wave on the transmission line. Intersection points on the $\mathrm{V}_{\mathrm{OH}} / \mathrm{l}_{\mathrm{OH}}$ curve will be waves travelling from the driver to the receiver while intersection points on the $\mathrm{V}_{\mathrm{IN}} / \mathrm{l}_{\mathrm{IN}}$ curve will be waves travelling from the receiver to the driver.
Figures 1 -3a thru $1-3 d$ show the resultant waveforms. Each division on the time scale represents the propagation delay of the transmission line.

## Dynamic Ouitut Drive (Continued)

While this exercise can be done for FACT, it is no longer necessary. FACT is guaranteed to drive an incident wave of enough voltage to switch another FACT input.
We can calculate what current is required by looking at the Bergeron diagram. The quiescent voltage on the line will be within 100 mV of either rail. We know what voltage is required to guarantee a valid voltage at the receiver. This is either $70 \%$ or $30 \%$ of $V_{D D}$. The formula for calculating the current and voltage required is $\left|\left(\mathrm{V}_{O Q}-\mathrm{V}_{1}\right) / \mathrm{Z}_{\mathrm{O}}\right|$ at $\mathrm{V}_{1}$. For $\mathrm{V}_{\mathrm{OQ}}=100 \mathrm{mV}, \mathrm{V}_{1 \mathrm{H}}=3.85 \mathrm{~V}, \mathrm{~V}_{\mathrm{DD}}=5.5 \mathrm{~V}$ and $\mathrm{Z}_{\mathrm{O}}=50 \Omega$, the required $\mathrm{I}_{\mathrm{OH}}$ at 3.85 V is 75 mA . For the HIGH-to-LOW transition, $\mathrm{V}_{\mathrm{OQ}}=5.4 \mathrm{~V}, \mathrm{~V}_{\mathrm{IL}}=1.65 \mathrm{~V}$ and $\mathrm{Z}_{\mathrm{O}}=50 \Omega$, $\mathrm{l}_{\mathrm{OL}}$ is 75 mA at 1.65 V . FACT's $1 / \mathrm{O}$ specifications include these limits. For transmission lines with impedances greater than $50 \Omega$, the current requirements are less and switching is still guaranteed.
It is important to note that the typical 24 mA DC drive specification is not adequate to guarantee incident wave switching. The only way to guarantee this is to guarantee the current required to switch a transmission line from the output quiescent point to the valid $V_{I N}$ level.
The following performance charts are provided in order to aid the designer in determining dynamic output current drive of FACT devices with various power supply voltages.

## Choice of Voltage Specifications

To obtain better performance and higher density, semiconductor technologies are reducing the vertical and horizontal dimensions of integrated device structures. Due to a number of electrical limitations in the manufacture of VLSI devices and the need for low voltage operation in memory cards, it was decided by the JEDEC committee to establish interface standards for devices operating at $3.3 \mathrm{~V} \pm 0.3 \mathrm{~V}$. To this end, National Semiconductor guarantees all of its devices operational at $3.3 \mathrm{~V} \pm 0.3 \mathrm{~V}$. Note also that $A C$ and $D C$ specifications are guaranteed between 3.0 V and 5.5 V . Operation of FACT logic is also guaranteed from 2.0 V to 6.0 V ' $\mathrm{AC} /{ }^{\prime} \mathrm{ACQ}$ on $\mathrm{V}_{\mathrm{DD}}$.

## Operating Voltage Ranges

```
FACT = 2.0V to 6.0V ('AC/'ACQ)
FACT = 5.0V \pm10% ('ACT/'ACTQ)
FACT = 5.0V }\pm5% ('FCT/'FCTA)
ALS = 5.0V \pm10%
LS = 5.0V }\pm5
HC = 2.0V to 6.0V
```

## FACT Replaces Existing Logic

National Semiconductor's Advanced CMOS family is specifically designed to outperform existing CMOS and Bipolar logic families. Figure $1-7$ shows the relative position of various logic families in speed/power performance. FACT exhibits 1 ns internal propagation delays while consuming $1 \mu \mathrm{~W}$ of power.
The Logic Family Comparisons table below summarizes the key performance specifications for various competitive technology logic families.

## Circuit Characteristics

## POWER DISSIPATION

One advantage to using CMOS logic is its extremely low power consumption. During quiescent conditions, FACT will consume several orders of magnitude less current than its bipolar counterparts. But DC power consumption is not the whole picture. Any circuit will have AC power consumption, whether it is built with CMOS or bipolar technologies.
Total power dissipation of FACT device under AC conditions is a function of three basic sources, quiescent power, internal dynamic power, and output dynamic power dissipation. Firstly, a FACT device will dissipate power in the quiescent or static condition. This can be calculated by using the formula: (Note: In many datasheets $I_{D D}, \Delta l_{D D}, I_{D D T}$, and $V_{D D}$ are referred to as $I_{C C}, \Delta I_{C C}, I_{C C T}$, and $V_{C C}$, respectively. There are no differences.)
Eq. $1 \quad P D_{Q}=I_{D D} \cdot V_{D D}$
$\mathrm{PD}_{\mathrm{Q}}=$ Quiescent Power Dissipation
IDD = Quiescent Power Supply Current Drain
$V_{D D}=$ Power Supply Voltage
Secondly, a FACT device will dissipate power dynamically by charging and discharging internal capacitance. This can be calculated by using one of the following two formulas:
Eq. 2A (AC/ACQ)
$P D_{\text {INT }}=\left(C_{P D} \bullet V_{S} \bullet f\right) \cdot V_{D D}$
$\mathrm{PD}_{\text {INT }}=$ Internal Dynamic Power Dissipation
$C_{P D}=$ Device Power Dissipation Capacitance
$V_{S}=$ Output Voltage Swing
$\mathrm{f}=$ Internal Frequency of Operation
$V_{D D}=$ Power Supply Voltage
$C_{P D}$ values are specified for each FACT device and are measured per JEDEC standards as described later on in Section 2. On FACT device data sheets, $\mathrm{C}_{P D}$ is a typical value and is given either for the package or for the individual stages with the device. (See Section 2). For FACT devices, $V_{S}$ and $V_{D D}$ are the same value and can be replaced by $V_{D D}{ }^{2}$ in the above formula.

Eq. 2 B (ACT/ACTQ)

| $P$ | $\begin{aligned} =\left[\left(I_{D T T} \bullet D_{H} \bullet N_{T}\right) \bullet V_{D}\right. \\ {\left[\left(C_{P D} \bullet V_{S} \bullet f\right) \bullet V_{D D}\right.} \end{aligned}$ |
| :---: | :---: |
| PDINT IDDT | $=$ Internal Dynamic Power Dissipation <br> = Power Supply Current for a TTL HIGH Input ( $\mathrm{V}_{\mathrm{IN}}=3.4 \mathrm{~V}$ ) |
| $\mathrm{D}_{\mathrm{H}}$ | $=$ Duty Cycle for TTL Inputs HIGH |
| $\mathrm{N}_{\text {T }}$ | $=$ Number of TTL Inputs at $\mathrm{D}_{\mathrm{H}}$ |
| $V_{D D}$ | = Power Supply Voltage |
| CPD | = Device Power Dissipation Capacitance |
| $\mathrm{V}_{S}$ | = Output Voltage Swing |
|  | rnal Frequency of O |

Eq. 2 C (FCT/FCTA)

$$
\begin{aligned}
P_{D_{I N T}}= & {\left[\left(\Delta I_{\mathrm{DD}} \bullet D_{H} \bullet N_{T}\right) \bullet V_{D D}\right]+\left[\left(l _ { D D } \bullet \left\{f_{C P} / 2\right.\right.\right.} \\
& \left.\left.\left.+f_{I N} \bullet N_{I N}\right\}\right) \bullet V_{D D}\right]
\end{aligned}
$$

PD ${ }_{\text {INT }}=$ Internal Dynamic Power Dissipation
$V_{D D}=$ Power Supply Voltage
$\Delta I_{D D}=$ Power Supply Current for a TTL HIGH Input ( $\mathrm{V}_{\mathrm{IN}}=3.4 \mathrm{~V}$ )
$\mathrm{D}_{\mathrm{H}} \quad=$ Duty Cycle for TTL Inputs HIGH
$N_{T}=$ Number of TTL Inputs at $D_{H}$
$I_{\text {DDD }}=$ Dynamic Current Caused by an Input Transition Pair (HLM or LHL)
$f_{C P}=$ Clock Frequency for Registered Devices (Zero for Non-Registered Devices)
$\mathrm{f}_{\mathrm{IN}}=$ Input Frequency
$\mathrm{N}_{\mathrm{IN}}=$ Number of Inputs at $\mathrm{f}_{\mathrm{IN}}$
See Section 3 for more information on $I_{\text {DDT }}$ or $\Delta I_{\text {DD }}$.
Thirdly, a FACT device will dissipate power dynamically by charging and discharging any load capacitance. This can be calculated by using the following formula:
Eq. 3 PD
PDOUT $=$ Output Power Dissipation
$C_{L} \quad=$ Load Capacitance
$V_{S} \quad=$ Output Voltage Swing
$f \quad=$ Output Operating Frequency
$V_{D D}=$ Power Supply Voltage

In many cases the output frequency is the same as the internal operation frequency. Also $\mathrm{V}_{S}$ is similar to $\mathrm{V}_{D D}$ and can be replaced by $V_{D D^{2}}$. In the case of internal and output frequencies beir:g identical Eq. 2A and Eq. 3 may be combined as follows:
Eq. $4 P D=\left(C_{L}+C_{P D}\right) \bullet V_{D D^{2}} \bullet f$
The total FACT device power dissipation is the sum of the quiescent power and all of the dynamic power dissipation. This is best described as:
$\begin{array}{ll}\text { Eq. } 5 & \text { PD }_{\text {TOTAL }}=P D_{Q}+P D_{\text {DYNAMIC }} \text { or } \\ & \text { PDTOTAL }\end{array}=P D_{Q}+P D_{\text {INT }}+P D_{\text {OUT }}$
The following is an exercise in calculating total dynamic lod for the FACT Advanced CMOS family. The device used as an example is the ACTQ374. Static $I_{D D}$, IDDT and $C_{P D}$ numbers can be found in the ACTQ374 data sheet. IDD numbers used will be worst-case commercial guarantees. Room temperature power will be less. These are approximate worstcase calculations.
The following assumptions have been made:

1. IDD will be calculated per input/output (as per JEDEC $\mathrm{C}_{\text {PD }}$ calculations). The total for the ACTQ374 will be the calculated $\mathrm{I}_{\mathrm{DD}} \times 8$.
2. Worst case conditions and JEDEC would require that the data is being toggled at the clock frequency in order to change the outputs at the maximum rate ( $1 / 2 \mathrm{CP}$ ).
3. The data and clock input signals are derived from TTL level drivers ( 0 V to 3.0 V swing) at $50 \%$ duty cycle.
4. The clock frequency is 16 MHz .
5. $\mathrm{I}_{\mathrm{DD}}$ will be calculated for $\mathrm{C}_{\mathrm{L}}=50 \mathrm{pF}, 100 \mathrm{pF}$ and 150 pF .
6. $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}$.
7. Total POWER dissipation can be obtained by multiplying total $I_{D D}$ by $V_{D D}(5.0 \mathrm{~V})$.
8. Quiescent $I_{D D}$ will be neglected in the total $I_{D D}$ calculation because it is 1000 times less than dynamic $l_{D D}$.
9. There is no DC load on the outputs, i.e. outputs are either unterminated or terminated with series or AC shunt termination.

The ldD calculations are as follows:
$I_{D D}$ Total $=$ Input $I_{D D}+$ Internal Switching I $I_{D D}+$ Output Switching (AC load) IDD
Input $I_{D D}=\left(I_{D D T}\right) \times$ (number of TTL inputs) $\times$ (Duty Cycle)
$=\left(1.5 \times 10^{-3}\right) \times(1) \times(0.50)$
$=0.75 \mathrm{~mA}$ per input being toggled at TTL levels
Internal $I_{D D}=\left(V_{\text {SWING }}\right) \times\left(C_{P D}\right) \times(C P$ freq $)$

$$
=(5.0) \times\left(42 \times 10^{-12}\right) \times\left(16 \times 10^{+6}\right)
$$

$=3.36$ per mA per input being toggled by CP
Output $I_{D D}=\left(V_{\text {SWING }} \times\left(C_{L}\right) \times(Q\right.$ freq $)$
a) $C_{L}=50 \mathrm{pF}$
$=(5.0) \times\left(50 \times 10^{-12}\right) \times\left(8 \times 10^{+6}\right)$
$=2 \mathrm{~mA}$ per output toggled at $1 / 2 \mathrm{CP}$
b) $\mathrm{C}_{\mathrm{L}}=100 \mathrm{pF}$
$=(5.0) \times\left(100 \times 10^{-12}\right) \times\left(8 \times 10^{+6}\right)$
$=4 \mathrm{~mA}$ per output toggled at $1 / 2 \mathrm{CP}$
c) $\mathrm{C}_{\mathrm{L}}=150 \mathrm{pF}$
$=(5.0) \times\left(150 \times 10^{-12}\right) \times\left(8 \times 10^{+6}\right)$
$=8 \mathrm{~mA}$ per output toggled at $1 / 2 \mathrm{CP}$
Adding Input, Internal and Output IDD together and multiplying by 8 I/O per ACTQ374, the approximate worst-case $l_{D D}$ calculations are as follows:

$$
\begin{aligned}
& C_{L}=50 \mathrm{pF} \quad \mathrm{I}_{\mathrm{DD}} \text { total }=48.9 \mathrm{~mA} \text { or } 244.5 \mathrm{~mW} * \text { at } \mathrm{CP} \\
& =16 \mathrm{MHz} \\
& C_{L}=100 \mathrm{pF} \quad I_{D D} \text { total }=64.9 \mathrm{~mA} \text { or } 324.5 \mathrm{~mW}^{*} \text { at } \mathrm{CP} \\
& =16 \mathrm{MHz} \\
& C_{L}=150 \mathrm{pF} \quad I_{D D} \text { total }=96.9 \mathrm{~mA} \text { or } 484.5 \mathrm{~mW}^{*} \text { at } \mathrm{CP} \\
& =16 \mathrm{MHz}
\end{aligned}
$$

(*Power is obtained by multiplying $\mathrm{I}_{\mathrm{DD}}$ by $\mathrm{V}_{\mathrm{DD}}$ )

## Circuit Characteristics (Continued)

TL/F/10158-11
FIGURE 1-9. Power Demonstration Circuit Schematic

The circuit shown in Figure 1-9 was used to compare the power consumption of FACT versus FAST devices.
Two identical circuits were built on the same board and driven from the same input. In the circuit, the input signal was driven into four D-type flip-flops which act as divide-by-2 frequency dividers. The outputs from the flip-flops were connected to the inputs of a ' 138 decoder. This generated eight non-overlapping clock pulses on the outputs of the '138, which were then connected to an '04 inverter. The input frequency was then varied and the power consumption was measured. Figure 1-10 illustrates the results of these measurements.

FIGURE 1-10. FACT vs FAST Circuit Power

## Circuit Characteristics (Continued)

The FACT circuit dissipates much less power than the FAST version. It is interesting to note that when the frequency went to zero, the FACT circuit's power consumption also went to zero; the FAST circuit continued to dissipate 200 mW .

## SPECIFICATION DERIVATION

At first glance, the specifications for FACT logic might appear to be widely spread, possibly indicating wide design margins are required. However, several effects are reflected in each specification.
Figures $1-11$ a through $1-11 i$ illustrate how the data from the characterization of actual devices is transformed into the specifications that appear on the data sheet. This data is taken from the 'XX244.

Figure 1-11a shows the data taken (from one part) on a typical, single path, $t_{\text {PHL }}$, over temperature at 5.0 V ; there is negligible variation in the value of $\mathrm{t}_{\mathrm{PHL}}$. The next set of graphs, Figure 1-11b through 1-11d, depict data taken on the same device; these sets of curves represents the data on all paths. The data on this plot indicates only a small variation for $t_{\text {PHL }}$.
The graphs in Figures 1-11a-d include data at 5.0V; Figure 1-11e shows the variation of delay times over the standard $5.0 \mathrm{~V} \pm 0.5 \mathrm{~V}$ voltage range. Note there is only a $\pm 6 \%$ variation in delay time due to voltage effects.
Now refer to Figure 1-11f which illustrates the process effects on delay time. This graph indicates that the process effects contribute to the spread in specifications more than any other factor in that the effects of the theoretical process spread can increase or decrease specification times by $30 \%$. Because this $30 \%$ spread represents considerably more than $\pm 3$ standard deviations, this guarantees an increase in the manufacturability and the quality level of FACT product. To further ensure parts within specification will pass on testers at the limits of calibration, tester guardbands are incorporated.
With voltage and process effects added (Figures $1-11 \mathrm{~g}$, 1-11h, and 1-11i), the full range of the specification can be seen. For reference, the data sheet values are shown on the graph.
This linear behavior with temperature and voltage is typical of CMOS. Although the graphs are drawn for a specific device, other part types have very similar graphical representations. Therefore, for performance-critical applications, where not all variables need to be taken into account at once, the user can narrow the specifications. For example, all parts in a critically timed subcircuit are together on a board, so it may be assumed the devices are at the same supply and temperature.

## Circuit Characteristics (Continued)

The same reasoning can be applied to setup and hold times. Consider the 'AC74. The setup time is 3.0 ns while the hold time is 0.5 ns . Theoretically, if these numbers were violated, the device would malfunction; however, in actuality, the device probably will not malfunction. Looking at the typical setup and hold times gives a better understanding of the device operation.
At $25^{\circ} \mathrm{C}$ and 5.0 V , the setup time is 1.0 ns while the hold time is -1.5 ns . They are virtually the same; a positive setup time means the control signal to be valid before the clock edge, a positive hold time indicates the control signal will be held valid after the clock edge for the specified time, and a negative hold time means the control signal can transition before the clock edge. FACT devices were designed to be as immune to metastability as possible. This is reflected in the typical specifications. The true "critical" time where the input is actually sampled is extremely short: less than 50 ps . By applying the same reasoning as we did to the propagation delays to the setup and hold times, it becomes obvious that the spread from setup to hold time ( 2.5 ns worst-case) really covers devices across the entire process/temperature/voltage spread. The real difference between the setup and hold times for any single device, at a specified temperature and voltage, is negligible.

## CAPACITIVE LOADING EFFECTS

In addition to temperature and power supply effects, capacitive loading effects for loads greater than 50 pF should be taken into account for propagation delays of FACT devices. Minimum delay numbers may be determined from the table below. Propagation delay are measured to the $50 \%$ point of the output waveform.

| Parameter |  | Voltage (V) |  |  | Units |
| :--- | :--- | :---: | :---: | :---: | :---: |
|  |  | $\mathbf{3 . 0}$ | $\mathbf{4 . 5}$ | $\mathbf{5 . 5}$ |  |
| tpLH | FACT AC | 31 | 22 | 19 |  |
|  | FACT QS | 34 | 19 | 19 | $\mathrm{ps} / \mathrm{pF}$ |
|  | FACT FCTA | 45 | 29 | 27 |  |
| t t PHL | FACT AC | 18 | 13 | 13 |  |
|  | FACT QS | 32 | 22 | 20 | $\mathrm{ps} / \mathrm{pF}$ |
|  | FACT FCTA | 17 | 13 | 12 |  |

$\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$
Figures 1-12 and 1-13, describe propagation delays on FACT devices as affected by variations in power supply voltage ( $\mathrm{V}_{\mathrm{DD}}$ ) and lumped load capacitance $\left(\mathrm{C}_{\mathrm{L}}\right)$. Figures 1-14 and $1-15$ show the effects of lumped load capacitance on rise and fall times for FACT devices.

## LATCH-UP

A major problem with CMOS has been its sensitivity to latch-up, usually attributed to high parasitic gains and high input impedance. FACT logic is guaranteed not to latch-up with dynamic currents of 100 mA ( 300 mA for FACT QS) forced into or out of the inputs or the outputs under worst case conditions ( $\mathrm{T}_{\mathrm{A}}=125^{\circ} \mathrm{C}$ and $\mathrm{V}_{\mathrm{DD}}=5.5 \mathrm{~V}_{\mathrm{DC}}$ ). At room temperature the parts can typically withstand dynamic currents of close to 1A. For most designs, latch-up will not be a problem, but the designer should be aware of its causes and how to prevent it.
FACT devices have been specifically designed to reduce the possibility of latch-up occurring; National Semiconductor accomplished this by lowering the gain of the parasitic transistors, reducing substrate and $p$-well resistivity to increase external drive current required to cause a parasitic to turn ON, and careful design and layout to minimize the sub-strate-injected current coupling to other circuit areas.

## ELECTROSTATIC DISCHARGE (ESD) SENSITIVITY

FACT circuits show excellent resistance to ESD-type damage. These logic devices are classified as category " $B$ " of MIL-STD-883C, test method 3015, and withstand in excess of 4000 V typically. FACT logic is guaranteed to have 2000 V ESD immunity on all inputs and outputs. Some FACT QS and FACT FCT/FCTA are guaranteed to have 4000V ESD immunity. FACT parts do not require any special handling procedures. However, normal handling precautions should be observed as in the case of any semiconductor device.
Figure $1-17$ shows the ESD test circuit used in the sensitivity analysis for this specification. Figure $1-18$ is the pulse waveform required to perform the sensitivity test.

FIGURE 1-15. $\mathrm{t}_{\text {fall }}$ vs Capacitance

FIGURE 1-16. FACT EPI Process Cross Section with Latch-up Circuit Model

## Circuit Characteristics (Continued)

The test procedure is as follows; five pulses, each of at least 2000 V , are applied to every combination of pins with a five second cool-down period between each pulse. The polarity is then reversed and the same procedure, pulse and pin combination used for an additional five discharges. Continue until all pins have been tested. If none of the devices from the sample population fails the DC and AC test characteristics, the device shall be classified as category B of MIL-STD-883C, TM-3015. Devices that result in ESD immunity in
the 2000V-3999V range are listed as ESD Class 2. Devices that result in ESD immunity in the $4000+V$ range are listed as ESD Class 3. Several devices on the FACT QS and FACT FCT/FCTA lines are guaranteed as Class 3 (see individual data sheets).
For further specifications of TM-3015, refer to the relevant standard. The voltage is increased and the testing procedure is again performed; this entire process is repeated until all pins fail. This is done to thoroughly evaluate all pins.

## Circuit Characteristics (Continued)

## RADIATION TOLERANCE

Semiconductors subjected to radiation environments undergo degradation in operating life as their exposure to radiation increases. As technology advances, so does the demand for radiation-tolerant devices. National is meeting this challenge by developing the FACT family into a comprehensive radiation tolerant product for present and future radhard needs. Such applications include:

- Space (Commercial and Military)
- Satellites
- Space Stations
- Airborne and Military (Tactical Arena)
- Fighters/Bombers
- Missile Systems
- Ground Based Systems
- Navigation \& Communications
- Commercial
- Power Stations
- Medical
- Food and Bacterial Control

Radiation tolerant semiconductors increase the useful life of the product in which they are incorporated. Additionally, radiation tolerant devices reduce shielding requirements and improve stabilization of parametric performance, resulting in cost reductions for shielding and weight, reduce power consumption and size.

## SUMMARY OF TESTING

FIGURE 1-19. Total Dose Response (54AC245)

Total dose irradiation is presently performed "in-house" using a AECL Gamma Cell 220, Cobalt-60, source (National Bureau of Standards certified). Step-stress radiation testing is performed on each part-type per MIL STD 883 Method 1019.3. After each total dose level, a complete parametric test ( $D C$ and $A C$ ) is done and the parametric values evaluated.

## FACT IS RADIATION TOLERANT

FACT logic employs the use of thin gate oxides, oxidation cycles, and annealing steps that enhance the tolerance of the standard FACT product line.
FACT's epitaxial layer and low-resistivity substrate provide inherent latch-up immunity under dose rate and single event phenomenon (SEP) conditions.
Figure 19 shows a FACT 'AC245 IDD supply current versus total dose radiation. With the exception of $l_{D D}$ and $l_{O Z}$, all FACT devices tested to date suffer no parametric degradation or functional failures up to several hundred krads. Due to circuit and layout differences, each function has a unique response to radiation. Relaxed limits for IDD and IOZ are per the applicable /750XX slash sheet, standard military drawing (SMD), or datasheet.

## DOSE RATE TEST RESULTS

Analysis of the FACT 54AC299 8-Bit Universal Shift Register upset test data indicates that minimum upset threshold levels occurred under the worst-case conditions of a wide pulse ( $1 \mu \mathrm{~s}$ ), lowest $\mathrm{V}_{D D}$ voltage ( 4.0 V DC ), and the DUT in the dynamic operating mode.
Measured minimum upset levels were 1.90 to $2.22 \times 10^{9}$ $\mathrm{rad}(\mathrm{Si}) / \mathrm{sec}$. Narrow pulse ( 50 ns ) data demonstrated radiation upset levels from 4.40 to $5.66 \times 10^{9} \mathrm{rad}(\mathrm{Si}) / \mathrm{sec}$ under dynamic operation.
Upon completion of radiation upset testing, latchup and survivability tests were performed at $+25^{\circ} \mathrm{C},+80^{\circ} \mathrm{C},+100^{\circ} \mathrm{C}$, and $+116^{\circ} \mathrm{C}$ for $\mathrm{V}_{\mathrm{DD}}=4.5 \mathrm{~V}$ DC, 5.0 V DC , and 5.5 V DC. Test results indicated no latchup occurred for either narrow pulse ( 50 ns ) or wide pulse ( 1 ms ) radiation. The radiation test level for narrow pulse was $10^{10} \mathrm{rad}(\mathrm{Si}) / \mathrm{sec}$ at $+25^{\circ} \mathrm{C}$. Due to the heating of the circuit, the highest radiation level was limited at $+116^{\circ} \mathrm{C}$ to $7.5 \times 10^{9} \mathrm{rad}(\mathrm{Si}) / \mathrm{sec}$.
After completion of latchup and survivability tests, verification of latchup windows was performed. Test results indicate no existence of latchup windows under worst case conditions for narrow and wide pulse radiation.

# Ratings, Specifications, and Waveforms 

## Specifying FACTTM Devices

Traditionally, when a semiconductor manufacturer completed a new device for introduction, specifications were based on the characterization of just a few parts. While these specifications were appealing to the designer, they were often too tight and, over time, the IC manufacturers had difficulty producing devices to the original specs. This forced the manufacturer to relax circuit specifications to reflect the actual performance of the device.
As a result, designers were required to review system designs to ensure the system would remain reliable with the new specifications. National Semiconductor realized and understood the problems associated with characterizing devices too aggressively.
To provide more realistic and manufacturable specs, $\mathrm{Na}-$ tional Semiconductor devised a systematic and thorough process to generate specifications. Devices are selected from multiple wafer lots to ensure process variations are taken into account. In addition, the process parameters are measured and compared to the known process limits. With more than five years of experience manufacturing FACT logic, National Semiconductor can accurately predict how these wafer lots compare with the best and worse case lots that can possibly be expected.
This method of characterizing parts more accurately represents the product across time, voltage, temperature and process rather than portraying the fastest possible device.
These specification guidelines allow designers to design systems more efficiently since the devices used will behave as documented. Unspecified guardbands no longer need to be added by the designer to ensure system reliability.

## Power Dissipation-Test Philosophy

In an effort to reduce confusion about measuring power dissipation capacitance, CPD, a JEDEC standard test procedure (7A Appendix E) has been adopted which specifies the test setup for each type of device. This allows a device to be exercised in a consistent manner for the purpose of specification comparison.
The following is a list of different types of logic functions, along with the input setup conditions under which the $\mathrm{C}_{\text {PD }}$ was measured for each type of device. By understanding how the device was exercised during $C_{P D}$ measurements, the designer can understand whether the CPD specified for that particular device reflects the total power dissipation ca-
pacitance for either the entire device or for just a certain stage of that device. For example, from the following list, it is apparent that the CPD value specified for a counter reflects the internal capacitance for the entire device, since the entire device is being exercised during measurement. On the other hand, the CPD value specified for an octal line driver reflects the internal capacitance for only one of eight stages, since only one input was being switched during test. Therefore the octal's overall power dissipation should be calculated for each of the eight stages, individually.
During the $C_{P D}$ measurements, each output that is being switched should be loaded with the standard 50 pF and $500 \Omega$ load. All device measurements are made with $\mathrm{V}_{\mathrm{DD}}=$ 5.0 V at $25^{\circ} \mathrm{C}$, with TRI-STATE ${ }^{\circledR}$ outputs enabled.

Gates/Buffers/ Switch one input. Bias the remaining Line Drivers: inputs such that one output switches. Latches: $\quad$ Switch the Enable and D inputs such that the latch toggles.
Flip-Flops: $\quad$ Switch the clock pin while changing $D$ (or bias J and K ) such that the output(s) change each clock cycle. For parts with a common clock, exercise only one flip-flop.
Decoders: Switch one address pin which changes two outputs.
Multiplexers: Switch one address pin with the corresponding data inputs at opposite logic levels so that the output switches.
Counters: $\quad$ Switch the clock pin with other inputs biased such that the device counts.
Shift Registers: Switch the clock pin with other inputs biased such that the device shifts.
Transceivers: Switch one data input. For bidirectional devices enable only one direction.
Parity Generator: Switch one input.
Priority Encoders: Switch the lowest priority input.

## AC Loading and Waveforms

## LOADING CIRCUIT

Figure 1 shows the AC loading circuit used in characterizing and specifying propagation delays of all FACT devices ('AC and 'ACT) unless otherwise specified in the data sheet of a specific device.

AC Loading and Waveforms (Continued) The use of this load, which is equivalent to the FAST® (Fairchild Advanced Schottky TTL) test jig, differs somewhat from previous (HCMOS) practice. This provides more meaningful information and minimizes problems of instrumentation and customer correlation. In the past, $+25^{\circ} \mathrm{C}$ propagation delays for TTL devices were specified with a load of 15 pF to ground; this required great care in building test jigs to minimize stray capacitance and implied the use of high impedance, high frequency scope probes. FAST circuits changed to 50 pF of capacitance, allowing more leeway in stray capacitance and also loading the device during rising or falling output transitions. This more closely resembles the inloading to be expected in avarage applications and thus gives the designer more useful delay figures. We have incorporated this scheme into the FACT product line. The net effect of the change in AC load is to increase the average observed propagation delay by about 1 ns .
The $500 \Omega$ resistor to ground can be a high frequency passive probe for a sampling oscilloscope, which costs much less than the equivalent high impedance probe. Alternately, the $500 \Omega$ resistor to ground can simply be a $450 \Omega$ resistor feeding into a $50 \Omega$ coaxial cable leading to a sampling scope input connector, with the internal $50 \Omega$ termination of the scope completing the path to ground. This is the preferred scheme for correlation. (See Figure 1.) With this scheme there should be a matching cable from the device input pin to the other input of the sampling scope; this also serves as a $50 \Omega$ termination for the pulse generator that supplies the input signal.
Shown in Figure 1 is a second $500 \Omega$ resistor from the device output to a switch. For most measurements this switch is open; it is closed for measuring one set of the Enable/

TL/F/10159-1
FIGURE 1a. AC Loading Circuit for AC, ACT, ACQ, ACTQ

Disable parameters (LOW-to-OFF and OFF-to-LOW) of a TRI-STATE output. With the switch closed, the pair of $500 \Omega$ resistors and the $2 \times V_{D D}$ supply voltage establish a quiescent HIGH level.

## Test Conditions

Figures $2 a$ and $2 b$ describe the input signal voltage levels to be used when testing FACT circuits. The AC test conditions follow industry convention requiring $V_{\mathbb{I N}}$ to range from $O V$ for a logic LOW to 3.0V for a logic HIGH for 'ACT devices and $O V$ to $V_{D D}$ for ' $A C$ devices. The $D C$ parameters are normally tested with $\mathrm{V}_{\text {IN }}$ at guaranteed input levels, that is $\mathrm{V}_{\mathrm{IH}}$ to $\mathrm{V}_{\mathrm{IL}}$ (see data tables for details). Care must be taken to adequately decouple these high performance parts and to protect the test signals from electrical noise. In an electrically noisy environment, (e.g., a tester and handler not specifically designed for high speed work), DC input levels may need to be adjusted to increase the noise margin to allow for the extra noise in the tester which would not be seen in a system.
Noise immunity testing is performed by raising $\mathrm{V}_{\mathrm{IN}}$ to the nominal supply voltage of 5.0 V then dropping to a level corresponding to $\mathrm{V}_{\mathrm{IH}}$ characteristics, and then raising again to the 5.0 V level. Noise tests can also be performed on the $\mathrm{V}_{\mathrm{IL}}$ characteristics by raising $\mathrm{V}_{\mathrm{IN}}$ from $O \mathrm{~V}$ to $\mathrm{V}_{\mathrm{IL}}$, then returning to OV. Both $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ noise immunity tests should not induce a switch condition on the appropriate outputs of the FACT device.
Good high frequency wiring practices should be used in constructing test jigs. Leads on the load capacitor should be as short as possible to minimize ripples on the output wave-

FIGURE 1b. AC Loading Circuit for FCT, FCTA

## Test Conditions (Continued)

TL/F/10159-3
FIGURE 2b. Test Input Signal Levels
form transitions and to minimize undershoot. Generous ground metal (preferably a ground plane) should be used for the same reasons. A $V_{D D}$ bypass capacitor should be provided at the test socket, also with minimum lead lengths.

## Rise and Fall Times

Input signals should have rise and fall times of 3.0 ns and signal swing of $O \mathrm{~V}$ to $3.0 \mathrm{~V} \mathrm{~V}_{\mathrm{DD}}$ for 'ACT devices or VV to $V_{D D}$ for ' $A C$ devices. Rise and fall times less than or equal to 1 ns should be used for testing $\mathrm{f}_{\text {max }}$ or pulse widths.
CMOS devices, including 4000 Series CMOS, HC, HCT and FACT families, tend to oscillate when the input rise and fall times become lengthy. As a direct result of its increased performance, FACT devices can be more sensitive to slow input rise and fall times than other lower performance technologies.
It is important to understand why this oscillation occurs. Consider the outputs, where the problem is initiated. Usually, CMOS outputs drive capacitive loads with low DC leakage. When the output changes from a HIGH level to a LOW level, or from a LOW level to a HIGH level, this capacitance has to be charged or discharged. With the present high performance technologies, this charging or discharging takes place in a very short time, typically 2-3 ns. The requirement to charge or discharge the capacitive loads quickly creates a condition where the instantaneous current change through the output structure is quite high. A voltage is generated across the $V_{D D}$ or ground leads inside the package due to the inductance of these leads. The internal ground of the chip will change in reference to the outside world because of this induced voltage.
Consider the input. If the internal ground changes, the input voltage level appears to change to the DUT. If the input rise time is slow enough, its level might still be in the device threshold region, or very close to it, when the output switches. If the internally-induced voltage is large enough, it is possible to shift the threshold region enough so that it recrosses the input level. If the gain of the device is sufficient and the input rise or fall time is slow enough, then the device may go into oscillation. As device propagation delays become shorter, the inputs will have less time to rise or fall through the threshold region. As device gains increase, the outputs will swing more, creating more induced voltage. Instantaneous current change will be greater as outputs become quicker, generating more induced voltage.

Package-related causes of output oscillation are not entirely to blame for problems with input rise and fall time measurements. All testers have $V_{D D}$ and ground leads with a finite inductance. This inductance needs to be added to the inductance in the package to determine the overall voltage which will be induced when the outputs change. As the reference for the input signals moves further away from the pin under test, the test will be more susceptible to problems caused by the inductance of the leads and stray noise. Any noise on the input signal will also cause problems. With FACT logic having gains as high as 100, it merely takes a 50 mV change in the input to generate a full 5 V swing on the output.

## Propagation Delays, $f_{\text {max }}$, Set and Hold Times

A 1.0 MHz square wave is recommended for most propagation delay tests. The repetition rate must necessarily be increased for testing $f_{\text {max }}$. A $50 \%$ duty cycle should always be used when testing $f_{\max }$. Two pulse generators are usually required for testing such parameters as setup time, hold time, recovery time, etc. See Figures 3, 4, and 8.

## Enable and Disable Times

Figures 5, 6 and 11 show that the disable times are measured at the point where the output voltage has risen or fallen by 0.3 V from $\mathrm{V}_{\mathrm{OL}}$ or $\mathrm{V}_{\mathrm{OH}}$, respectively. This change enhances the repeatability of measurements, and gives the system designer more realistic delay times to use in calculating minimum cycle times. Since the high impedance state rising or falling waveform is RC-controlled, the first 0.3 V of change is more linear and is less susceptible to external influences. More importantly, perhaps from the system designer's point of view, a change in voltage of 0.3 V is adequate to ensure that a device output has turned OFF. Measuring to a larger change in voltage merely exaggerates the apparent Disable times and thus penalizes system performance since the designer must use the Enable and Disable times to devise worst case timing signals to ensure that the output of one device is disabled before that of another device is enabled. Note that the measurement points have been changed from the previous $10 \%$ and $90 \%$ points. This better reflects actual test points and does not change specification limits.

## Electrostatic Discharge

Precautions should be taken to prevent damage to devices by electrostatic discharge. Static charge tends to accumulate on insulated surfaces such as synthetic fabrics or carpeting, plastic sheets, trays, foam, tubes or bags, and on ungrounded electrical tools or appliances. The problem is much worse in a dry atmosphere. In general, it is recommended that individuals take the precaution of touching a known ground before handling devices. To effectively avoid electrostatic damage to FACT devices, it is recommended that individuals wear a grounded wrist strap when handling devices. More often, handling equipment, which is not properly grounded, causes damage to parts. Ensure that all plastic parts of the tester, which are near the device, are conductive and connected to ground.

## FACT Noise Characteristics

The setup of a noise characteristics measurement is critical to the accuracy and repeatability of the tests. The following is a brief description of the setup used to measure the noise characteristics of FACT.
Equipment:
Hewlett Packard Model 8180A Word Generator
PC-163A Test Fixture or Equivalent
Tektronics Model 7854 Oscilloscope or Equivalent
Procedure:

1. Verify Test Fixture Loading: Standard Load $50 \mathrm{pF}, 500 \Omega$.
2. Deskew the word generator so that no two channels have greater than 150 ps skew between them. This requires that the oscilloscope be deskewed first. Swap out the channels that have more than 150 ps of skew until all channels being used are within 150 ps. It is important to deskew the word generator channels before testing. This will ensure that the outputs switch simultaneously.
3. Terminate all inputs and outputs to ensure proper loading of the outputs and that the input levels are at the correct voltage.
4. Set $\mathrm{V}_{\mathrm{DD}}$ to 5.0 V .
5. Set the word generator to toggle all but one output at a frequency of 1 MHz . Greater frequencies will increase DUT heating and affect the results of the measurement.
6. Set the word generator input levels at OV LOW and 3V HIGH for ACT/ACTQ/FCT/FCTA devices and OV LOW and 5 V HIGH for AC/ACQ devices. Verify levels with a digital volt meter.

FIGURE 12. Quiet Output Noise Voltage Waveforms
Note $A$. $V_{O H V}$ and $V_{\text {OLP }}$ are measured with respect to ground reference.
Note B. Input pulses have the following characteristics: $f=1 \mathrm{MHz}, \mathrm{t}_{\mathrm{r}}=$ $3 \mathrm{~ns}, \mathrm{t}_{\mathrm{f}}=3 \mathrm{~ns}$, skew $<150 \mathrm{ps}$.
$\mathrm{V}_{\text {OLP }} / \mathrm{V}_{\text {OLV }}$ and $\mathrm{V}_{\mathrm{OHP}} / \mathrm{V}_{\mathrm{OHV}}$ :

- Determine the quiet output pin that demonstrates the greatest noise levels. The worst case pin will usually be the furthest from the ground pin. Monitor the output voltages using a $50 \Omega$ coaxial cable plugged into a standard SMB type connector on the test fixture. Do not use an active FET probe.
- Measure $V_{\text {OLP }}$ and $V_{\text {OLV }}$ on the quiet output LOW during the HL transition. Measure $\mathrm{V}_{\mathrm{OHP}}$ and $\mathrm{V}_{\mathrm{OHV}}$ on the quiet output HIGH during the LH transition.
- Verify that the GND reference recorded on the oscilloscope has not drifted to ensure the accuracy and repeatability of the measurements.
$\mathrm{V}_{\text {ILD }}$ and $\mathrm{V}_{\text {IHD }}$ :
- Monitor one of the switching outputs using a $50 \Omega$ coaxial cable plugged into a standard SMB type connector on the test fixture. Do not use an active FET probe.
- First increase the input LOW voltage level, $\mathrm{V}_{\mathrm{IL}}$, until the output begins to oscillate. Oscillation is defined as noise on the output LOW level that exceeds $\mathrm{V}_{\mathrm{IL}}$ limits, or on output HIGH levels that exceed $\mathrm{V}_{\mathbb{I}}$ limits. The input LOW voltage level at which oscillation occurs is defined as $V_{\text {ILD }}$.
- Next increase the input HIGH voltage level on the word generator, $\mathrm{V}_{\mathrm{IH}}$ until the output begins to oscillate. Oscillation is defined as noise on the output LOW level that exceeds $V_{I L}$ limits, or on output HIGH levels that exceed $\mathrm{V}_{\mathrm{IH}}$ limits. The input HIGH voltage level at which oscillation occurs is defined as $V_{I H D}$.
- Verify that the GND reference recorded on the oscilloscope has not drifted to ensure the accuracy and repeatability of the measurements.

Today's system designer is faced with the problem of keeping ahead when addressing system performance and reliability. National Semiconductor's advanced CMOS helps designers achieve these goals.
FACTTM (Fairchild Advanced CMOS Technology) logic was designed to alleviate many of the drawbacks that are common to current technology logic circuits. FACT logic combines the low static power consumption and the high noise margins of CMOS with a high fan-out, low input loading and a $50 \Omega$ transmission line drive capability (comparable to Na tional Semiconductor's FAST bipolar technology family) to offer a complete family of 1.3 -micron SSI, MSI, and LSI devices.

Performance features such as advanced Schottky speeds at CMOS power levels, advanced Schottky drive, excellent noise, ESD, and latch-up immunity are characteristics that designers of state-of-the-art systems require. FACT logic answers all of these concerns in one family of products. To fully utilize the advantages provided by FACT, the system designer should have an understanding of the flexibility as well as the trade-offs of CMOS design. The following section discusses common design concerns relative to the performance and requirements of FACT.

There are six items of interest which need to be evaluated when implementing FACT devices in new designs:

- Interfacing-interboard and technology interfaces, battery backup and power down or live insert/extract systems require some special thought.
- Transmission Line Driving-FACT has line driving capabilities superior to all CMOS families and most TTL families.
- Noise effects-As edge rates increase, the probability of crossialk and ground bounce problems increases. The enhanced noise immunity and high threshold levels improve FACT's resistance to system-generated problems.
- Board Layout-Prudent board layout will ensure that most noise effects are minimized.
- Power Supplies and Decoupling-Maximize ground and $V_{D D}$ traces to keep $V_{D D}$ /ground impedance as low as possible; full ground/VDD planes are best. Decouple any device driving a transmission line; otherwise add one capacitor for every package.
- Electromagnetic Interference

## Interfacing

FACT and FACT QS devices have outputs which combine balanced CMOS outputs with high current line driving capability. Each standard output is guaranteed to source or sink

24 mA of current under worst case conditions. FACT FCT is guaranteed to sink 64 mA and source 15 mA . This allows FACT circuits to drive more loads than standard advanced Schottky parts; FACT can directly drive FAST®, ALS, AS, LS, HC and HCT devices.

FIGURE 3-1. Interfacing FACT to NMOS, CMOS, and TTL
FACT devices can be directly driven by both NMOS and CMOS families, operating at the same rail potential without special considerations. This is possible due to the low input loading of FACT product, guaranteed to be less than $1 \mu \mathrm{~A}$ per input.
Some older technologies, including all existing TTL families, will not be able to drive FACT AC/ACQ circuits directly; this is due to inadequate output HIGH level capability, which is guaranteed to 2.4 V . There are two simple approaches to the TTL-to-FACT interface problem. A TTL-to-CMOS converter can be constructed employing a resistor pull-up to $V_{D D}$ of approximately $4.7 \mathrm{k} \Omega$, which is depicted in Figure 3-2. The correct HIGH level is seen by the CMOS device while not loading down the TTL driver.

FIGURE 3-2. $\mathrm{V}_{\mathrm{IH}}$ Pull-Up on TTL Outputs
Unfortunately, there will be designs where including a pullup resistor will not be acceptable. In these cases, such as a terminated TTL bus, National Semiconductor has designed devices which offer thresholds that are TTL-compatible (Figure 3-3).

Interfacing (Continued)

TL/F/10160-3
FIGURE 3-3. TTL Interfacing to 'ACT
ECL devices cannot directly drive FACT devices. Interfacing FACT-to-ECL can be accomplished by using a F100124 or F100324 TTL-to-ECL translator and a F100125 or F100325 ECL-to-TTL translator in addition to following the same rules on the TTL outputs to CMOS inputs (i.e., a resistor pull-up to $V_{D D}$ of approximately $4.7 \mathrm{k} \Omega$ ).

FIGURE 3-4a. FACT-to-ECL Translation

TL/F/10160-5
FIGURE 3-4b. ECL-to-FACT Translation
It should be understood that for FACT, as with other CMOS technologies, input levels that are between specified input values will cause both transistors in the CMOS structure to be conducting. This will cause a low resistive path from the supply rail to ground, increasing the power consumption by several orders of magnitude. It is important that CMOS inputs are always driven as close as possible to the rail.

## Line Driving and Termination

With the available high-speed logic families, designers can reach new heights in system performance. Yet, these faster devices require a closer look at transmission line effects.

Although all circuit conductors have transmission line properties, these characteristics become more significant when the edge rates of the drivers are equal to or less than three times the propagation delay of the line. Significant transmission line properties may be exhibited in an example where devices have edge rates of 3 ns and lines of 8 inches or greater, assuming propagation delays of $1.7 \mathrm{~ns} / \mathrm{ft}$ for an unloaded printed circuit trace.
Of the many properties of transmission lines, two are of major interest to the system designer: $Z^{\prime}{ }_{0}$, the effective equivalent impedance of the line, and $t_{\text {pde }}$, the effective propagation delay down the line. It should be noted that the intrinsic values of line impedance and propagation delay, $Z_{0}$ and $t_{p d}$, are geometry-dependent. Once the intrinsic values are known, the effects of gate loading can be calculated. The loaded values for $Z^{\prime}{ }_{o}$ and $t_{p d e}$ can be calculated with:

$$
\begin{aligned}
Z_{o}^{\prime} & =\frac{Z_{o}}{\sqrt{1+C_{D} / C_{L}}} \\
t_{\text {pde }} & =t_{p d} \sqrt{1+C_{D} / C_{L}}
\end{aligned}
$$

where $C_{L}=$ intrinsic line capacitance and $C_{D}=$ additional capacitance due to gate loading.
The formulas indicate that the loading of lines decreases the effective impedance of the line and increases the propagation delay. Lines that have a propagation delay greater than one third the rise time of the signal driver should be evaluated for transmission line effects. When performing transmission line analysis on a bus, only the longest, most heavily loaded and the shortest, least loaded lines need to be analyzed. All lines in a bus should be terminated equally; if one line requires termination, all lines in the bus should be terminated. This will ensure similar signals on all of the lines.

- Termination Impedance $=Z_{T}$
- Voltage at Termination $=V_{T}$

FIGURE 3-5b. Reflections Due to Impedance Mismatching

There are several termination schemes which may be used. Included are series, parallel, AC parallel, and Thevenin terminations. AC parallel and series terminations are the most useful for low power applications since they do not consume any DC power. Parallel and Thevenin terminations experience high $D C$ power consumption.

## SERIES TERMINATIONS

Series terminations are most useful in high-speed applications where most of the loads are at the far end of the line or especially for single point loads. Loads that are between the driver and the end of the line will receive a two-step
waveform. The first step will be the incident wave, $\mathrm{V}_{\mathrm{i}}$. The amplitude is dependent upon the output impedance of the driver, the value of the series resistor, and the impedance of the line according to the formula

$$
V_{i}=V_{D D} \cdot Z^{\prime}{ }_{0} /\left(Z_{0}^{\prime}+R_{S}+Z_{S}\right)
$$

The amplitude will be one-half the voltage swing if $R_{S}$ (the series resistor) plus the output impedance ( $Z_{\mathrm{s}}$ ) of the driver is equal to the line impedance. $Z_{S}$ for FACT is approximately $17 \Omega$. The second step of the waveform is the reflection from the end of the line and will have an amplitude equal to that of the first step. All devices on the line will receive a

## Line Driving and Termination (Continued)

valid level only after the wave has propagated down the line and returned to the driver. Therefore, all inputs will see the full voltage swing within two times the delay of the line.

## PARALLEL TERMINATION

Parallel terminations are not generally recommended for CMOS circuits due to their power consumption, which can exceed the power consumption of the logic itself. The power consumption of parallel terminations is a function of the resistor value and the duty cycle of the signal. In addition, parallel termination tends to bias the output levels of the driver towards either $V_{D D}$ or ground. While this feature is not desirable for driving CMOS inputs, it can be useful for driving TTL inputs.

## AC PARALLEL TERMINATION

AC parallel terminations work well for applications where the delays caused by series terminations are unacceptable. The terminating effects of AC parallel terminations are similar to the effects of standard parallel terminations. The major difference is that the capacitor blocks any DC current path and helps to reduce power consumption.

## Thevenin Termination

Thevenin terminations are also not generally recommended due to their power consumption. Like parallel termination, a DC path to ground is created by the terminating resistors. The power consumption of a Thevenin termination, though, will generally not be a function of the signal duty cycle. Thevenin terminations are more applicable for driving CMOS inputs because they do not bias the output levels as paralleled terminations do. It should be noted that lines with Thevenin terminations should not be left floating since this will cause the input levels to float between $V_{D D}$ or ground, increasing power consumption.

- Parallel:

$$

■ AC:

Figure 3-6b. Suggested Termination Values

TL/F/10160-13
FIGURE 3-6c. FACT IDD vs Termination

FACT circuits have been designed to drive $50 \Omega$ transmission lines over the full commercial temperature range and $75 \Omega$ transmission lines over the military temperature range. This is guaranteed by the FACT family's specified dynamic drive capability of 75 mA source and sink current. This ensures incident wave switching on $50 \Omega$ transmission lines and is consistent with the 3 ns rated edge transition time.
FACT and FACT QS devices also feature balanced output totem pole structures to allow equal source and sink current capability. This gives rise to balanced edge rates and equal rise and fall times. Balanced drive capability and transition times eliminate both the need to calculate two different delay times for each signal path and the requirement to correct signal polarity for the shortest delay time.
FACT FCT/FCTA have very high DC sink current capability ( 64 mA , commercial temperature) making the output drive compatible with popular bus standards such as VMEbus ${ }^{\text {TM }}$ and MULTIBUS®.
FACT product inputs have been created to take full advantage of high output levels to deliver the maximum noise immunity to the system designer. $\mathrm{V}_{\mathrm{IH}}$ and $\mathrm{V}_{\mathrm{IL}}$ for AC/ACQ devices are specified at $70 \%$ and $30 \%$ of $V_{D D}$ respectively. The corresponding output levels, $\mathrm{V}_{\mathrm{OH}}$ and $\mathrm{V}_{\mathrm{OL}}$, are specified to be within 0.1 V of the rails, of which the output is sourcing or sinking $50 \mu \mathrm{~A}$ or less. These noise margins are outlined in Figure 3-7.

TL/F/10160-14
FIGURE 3-7. AC/ACQ input Threshold

## CMOS Bus Loading

CMOS logic devices have clamp diodes from all inputs and outputs to $V_{D D}$ and ground. While these diodes increase system reliability by damping out undershoot and overshoot noise, they can cause problems if power is lost.
Figure 3-8 exemplifies the situation when power is removed. Any input driven above the $\mathrm{V}_{\mathrm{DD}}$ pin will forward-bias the clamp diode. Current can then flow into the device, and out $V_{D D}$ or any output that is HIGH. Depending upon the system, this current, $\mathrm{I}_{\mathbb{N}}$, can be quite high, and may not allow the bus voltage to reach a valid HIGH state. One possible solution to eliminate this problem is to place a series resistor in the line. Another possible solution would be to ensure that the output enable input is inactive, preventing the outputs from turning on and loading down the bus. This may be accomplished by hardwiring a $4.7 \mathrm{k} \Omega$ pull-up resistor to the $V_{D D}$ pin of the FACT device.

FIGURE 3-8. Noise Effects

## Noise Effects

FACT offers the best noise immunity of any competing technology available today. With input thresholds specified at $30 \%$ and $70 \%$ of $V_{D D}$ and outputs that drive to within 100 mV of the rails, FACT AC/ACQ devices offer noise margins approaching $30 \%$ of $V_{D D}$. At $5 \mathrm{~V} V_{D D}$, FACT's specified input and output levels give almost 1.5 V of noise margin for both ground- and $V_{D D}$-born noise. With realistic input thresholds closer to $50 \%$ of $V_{D D}$, the actual margins approach 2.5 V .
However, even the most advanced technology cannot alone eliminate noise problems. Good circuit board layout techniques are essential to take full advantage of the superior performance of FACT circuits.
Well-designed circuit boards also help eliminate manufacturing and testing problems.
Another recommended practice is to segment the board into a high-speed area, a medium-speed area and a lowspeed area. The circuit areas with high current requirements (i.e., buffer circuits and high-speed logic) should be as close to the power supplies as possible; low-speed circuit areas can be furthest away.
Decoupling capacitors should be adjacent to all buffer chips; they should be distributed throughout the logic: one capacitor per chip. Transmission lines need to be terminated to keep reflections minimal. To minimize crosstalk, long signal lines should not be close together.

## Crosstalk

The problem of crosstalk and how to deal with it is becoming more important as system performance and board densities increase. Crosstalk is the coupling of signals from one line to another. The amplitude of the noise generated on the inactive line is directly related to the edge rates of the signal on the active line, the proximity of the two lines and the distance that the two lines are adjacent.
Crosstalk has two basic causes. Forward crosstalk, Figures $3-9 b$ and $3-9 d$, is caused by the wavefront propagating down the printed circuit trace at two different velocities. This difference in velocities is due to the difference in the dielectric constants of air ( $\epsilon_{\mathrm{r}}=1.0$ ) and epoxy glass ( $\epsilon_{\mathrm{r}}=4.7$ ). As the wave propagates down the trace, this difference in velocities will cause one edge to reach the end before the other. This delay is the cause of forward crosstalk; it increases with longer trace length, so consequently the magnitude of forward crosstalk will increase with distance.
Reverse crosstalk, Figures $3-9 \mathrm{C}$ and $3-9 e$, is caused by the mutual inductance and capacitance between the lines which is a transformer action. Reverse crosstalk increases linearly with distance up to a critical length. This critical length is the distance that the signal can travel during its rise or fall time. Although crosstalk cannot be totally eliminated, there are some design techniques that can reduce system problems resulting from crosstalk. FACT's industry-leading noise margins make systems immune to crosstalk-related problems easier to design. FACT's AC noise margins, shown in Figures 3-10a through 3-10f, exemplify the outstanding immunity to everyday noise which can effect system reliability.

FIGURE 3-10d. Low Noise Margin

With over 2.0 V of noise margins, the FACT family offers better noise rejection than any other comparable technology.
In any design, the distance that lines run adjacent to each other should be kept as short as possible. The best situation is when the lines are perpendicular to each other. For those situations where lines must run parallel, the effects of cross-

talk can be minimized by line termination. Terminating a line in its characteristic impedance reduces the amplitude of an initial crosstalk pulse by $50 \%$. Terminating the line will also reduce the amount of ringing. Crosstalk problems can also be reduced by moving lines further apart or by inserting ground lines or planes between them.

## Decoupling Requirements

National Semiconductor Advanced CMOS, as with other high-performance, high-drive logic families, has special decoupling and printed circuit board layout requirements. Adhering to these requirements will ensure the maximum advantages are gained with FACT products.
Local high frequency decoupling is required to supply power to the chip when it is transitioning from a LOW to HIGH value. This power is necessary to charge the load capacitance or drive a line impedance. Figure 3-12 displays various $V_{D D}$ and ground layout schemes along with associated impedances.

For most power distribution networks, the typical impedance is between $50 \Omega$ and $100 \Omega$. This impedance appears in series with the load impedance and will cause a droop in the $V_{D D}$ at the part. This limits the available voltage swing at the local node, unless some form of decoupling is used. This drooping of rails will cause the rise and fall times to become elongated. Consider the example described in Figure 3-13 to calculate the amount of decoupling necessary. This circuit utilizes an 'AC240 driving a $100 \Omega$ bus from a point somewhere in the middle.

FIGURE 3-13. Octal Buffer Driving a $100 \Omega$ Bus

FIGURE 3-12. Power Distribution Impedances

## Decoupling Requirements (Continued)

Being in the middle of the bus, the driver will see two $100 \Omega$ loads in parallel, or an effective impedance of $50 \Omega$. To switch the line from rail to rail, a drive of 94 mA is needed; more than 750 mA will be required if all eight lines switch at once. This instantaneous current requirement will generate a voltage drop across the impedance of the power lines, causing the actual $V_{D D}$ at the chip to droop. This droop limits the voltage swing available to the driver. The net effect of the voltage droop will lengthen device rise and fall times and slow system operation. A local decoupling capacitor is required to act as a low impedance supply for the driver chip during high current conditions. It will maintain the voltage within acceptable limits and keep rise and fall times to a minimum. The necessary values for decoupling capacitors can be calculated with the formula given in Figure 3-14.
In this example, if the $V_{D D}$ droop is to be kept below 30 mV and the edge rate equals 4 ns , a $0.10 \mu \mathrm{~F}$ capacitor is needed.
It is good practice to distribute decoupling capacitors evenly through the logic, placing one capacitor for every package.

Select $C_{B} \geq 0.10 \mu F$
FIGURE 3-14. Formula for Calculating Decoupling Capacitors

## Capacitor Types

Decoupling capacitors need to be of the high K ceramic type with low equivalent series resistance (ESR), consisting primarily of series inductance and series resistance. Capacitors using 5ZU dielectric have suitable properties and make a good choice for decoupling capacitors; they offer minimum cost and effective performance.

- Need to decouple board at the point of power supply entry

TL/F/10160-28

- This capacitor $(A)$ will smooth low frequency bulk switching noise
- A large value electrolytic capacitor is typically used ( $50 \mu \mathrm{~F}-100 \mu \mathrm{~F}$ )

## Electromagnetic Interference

One of the features of advanced CMOS is its fast output edge rates. For the first time a non-ECL logic family is capable of switching outputs at ECL speeds. In fact, advanced CMOS edge rates exceed that of ECL. ECL outputs typically swing 900 mV in 700 ps , translating into an edge rate of 1.3 V/ns. Advanced CMOS outputs, on the other hand, swing 5.0 V in approximately 3.0 ns , translating into an edge rate of $1.6 \mathrm{~V} / \mathrm{ns}$. Logic families driving at these speeds, however, are more prone to generate higher levels of system noise. Electronic systems using advanced CMOS logic, as with any other high performance logic system, require a higher level of design considerations.
One element of system noise that will be discussed here is referred to as Electromagnetic Interference, or EMI. The level of EMI generated from a system can be greatly reduced with the use of proper Electromagnetic Compatibility (EMC) design techniques. These design considerations begin at the circuit board level and continue through the system level to the enclosures themselves; EMC needs to be a concern at the initial system design stage.

## WHAT IS EMI/RFI?

Electromagnetic Interference, or EMI, is an electrical phenomenon where electric field energy and magnetic field energy are transmitted from one source to create interference of transmitted and/or received signals from another source. This may result in the information becoming distorted.
EMI can be an issue of emissions, that is, energy radiated from one system to another or within the same system. It can also be an issue of susceptibility, from high powered microwave signals or nuclear EMP (Electromagnetic Pulse)-an issue more applicable in the military arena than commercial. While this section will specifically address radiated energy, many comments may also apply to susceptibility.

## SOURCES OF ELECTROMAGNETIC INTERFERENCE

EMI generation in an electronic system may result from several sources. All mediums of signal transmission-from the signal origin to its destination-are possible sources of radiated EMI. Understanding how each medium-including ICs, coaxial cables, and connectors-can radiate EMI is paramount in effective, high performance system design.
As Figure 3-16 illustrates, EMI in a typical electronic circuit is generated by a current flowing in some current path configured within the circuit. These paths can be either $V_{D D}$-toGND loops or output transmission lines. The propagating current pulse creates magnetic field energy, while the voltage drop across the loop area creates electric field energy. The current path material itself acts as an antenna radiat-ing-or receiving-both the electric and magnetic fields.
EMI generation is a function of several factors. Transmitted signal frequency, duty cycle, edge rate, and output voltage swings are the major factors of the resultant EMI levels. Figure 3-17 illustrates a generalized Fourier transformation of the transmitted signal from the time domain to the fre-
quency domain. To think in terms of EMI, one must think in terms of the frequency domain. This illustration helps to realize the role of the time domain signal components in the frequency domain. Notice that as the signal's period decreases, duty cycle decreases, or rise/fall time decreases that the radiated bandwidth increases.
On the circuit level, in addition to the signal component factors mentioned earlier, radiatirig area, and the resultant antenna's radiating efficiency also play an important role in EMI generation. Also, current spikes, power line noise, and output ringing caused by outputs switching also contribute to the overall EMI. Good design techniques that moderate this noise will play a major role in minimizing radiated EMI.

## OVERALL SYSTEM EMI

System EMI is a function of the current loop area. Some of the largest loop areas in a system consist of circuit board signal transmission lines, backplane transmission lines, and 1/O cables. The current loop areas of the integrated circuit
 those of the transmission lines and I/O cables. Differences in IC package pinout schemes are much less noticeable in terms of overall system radiated EMI.
The formula used to model the maximum electric field is listed below. This formula takes into account the antenna dimension and efficiency as well as the basic signal components.
$|E|_{\text {Max }}=\frac{1.32 \times 10^{-3} \bullet \mid \cdot A \cdot \text { Freq }^{2}}{D}\left[1+\left(\frac{\lambda}{2} \pi D\right)^{2}\right]^{1 / 2} \frac{\mu V}{m}$ where,
$|E|_{\text {Max }}$ is the maximum E-field in the plane of the loop $I$ is the current amplitude in milliamps
$A$ is the antenna area in square cm
$\lambda$ is the wavelength at the frequency of interest
$D$ is the observation distance in meters
Freq is the frequency in MHz
and the perimeter of the loop $\mathrm{P} \ll \lambda$.
Figures 3-18a and 3-18b illustrate lab measurements of radiated emissions from a test board populated with FACT, FACT QS, and a competitor's ACMOS logic. The device under test is driving a similar device across 26 cm of printed circuit board trace.
At higher frequencies where, for example, quarter wavelengths approach the lengths of transmission lines common in typical backplanes and plug-in cards, FACT QS with its innovative noise supressions circuitry radiates substantially less EMI than other ACMOS logic.

## CIRCUIT BOARD DESIGN CONSIDERATIONS

Original equipment manufacturers cannot afford to fail electromagnetic emissions tests. Since these tests are measured outside of the system, precautions to shield the enclosures, I/O cables, and connections are paramount. However, EMI within a system may also cause errors in data trans-

## Electromagnetic Interference (Continued)

mission or unreliable system operation. Therefore, good EMC design techniques at the circuit board level are just as necessary.
Designing a system free of all EMI is an overwhelming task. However, considering the following design recommendations at the circuit board level forms a good foundation on which to design a system with good EMC.

- The use of multilayer printed circuit board is a virtual necessity. Two-sided printed circuit board and wire-wrap boards provide no shielding of EMI. Two-sided boards also do not allow the use of power and ground planes. Instead they require the use of high impedance power and ground traces. Planes provide impedances several orders of magnitude lower than that of traces, reducing transient voltage drops in the power distribution and return loops. As a result of these lower voltage drops, power supply induced EMI can also be reduced.
- In addition to the reduced impedance, these power and ground planes have an inherent EMI shielding effect that the large areas of copper provide. With the use of striplines or signal transmission lines sandwiched between the power and ground planes, the designer can take full advantage of the planes' shielding capabilities. To maximize this shielding effect, keep the power and ground plane areas as homogeneous as possible.
- Since plastic provides no EMI shielding, and sockets of any profile provide plenty of lead length, ICs should be soldered directly to the board. Solder power and ground pins directly to the power and ground planes, respectively. Minimize the IC and associated component lead lengths wherever possible.
- Minimizing the number of simultaneously switching outputs will also help to moderate the current pulse amplitude and output ringing.
- Terminating signal traces longer than 8 inches (typical) will minimize reflections and ringing due to those reflections.
- Avoid capacitively coupling signals from one transmission line to another-crosstalk-by avoiding long parallel signal transmission lines. If parallel transmission lines are unavailable, maximize the distance between the two lines, or insert a ground trace. Minimizing the spacing between the signal plane and ground plane will also help reduce crosstalk. For more details, see section on Crosstalk.

## POWER SUPPLY DECOUPLING CONSIDERATIONS

Much of a system's radiated EMI may originate from the power supply itself. Propagation of power supply noise throughout a system is a very undersirable situation in any respect, including EMI. Suppression of this power supply noise is highly recommended. Decoupling the power supply at every level, from the system supply distribution network, down to the individual IC, is also a necessity when designing for low noise-and low EMI.

- On the system level, the use of a tantalum or aluminum electrolytic capacitor in the power supply distribution network is recommended.
- Decoupling the power supply at the point of entry onto the printed circuit board is also highly recommended. The use of a low equivalent series inductance, or ESL, multilayer ceramic capacitor, $50 \mu \mathrm{~F}$ to $100 \mu \mathrm{~F}$, provides good low to medium frequency filtering and EMI suppression.
- To further suppress power supply noise and associated EMI throughout the circuit board itself, the use of a low ESL chip capacitor for each IC is highly recommended. Because the location of any transient noise on a power or ground plane would be impossible to predict, and the IC density of different circuit boards vary dramatically, every IC on these circuit boards should be adequately decoupled. A $0.10 \mu \mathrm{~F}$ chip capacitor, located as close to each ground pin as possible, will provide good high frequency power supply noise filtering and added EMI suppression.

## BACKPLANE CONSIDERATIONS

The above discussion emphasized design techniques for printed circuit boards. However, because the backplane may, and usually does, consist of several long signal transmission lines, the same low noise design techniques should be used.

- Multilayer board techniques should also be applied to the backplane. If possible, these transmission lines should be shielded individually. This would allow for a denser parallel layout of transmission lines as well as providing good EMC.
- Use multiple ground and power connections from the backplane to the circuit boards' power and ground planes to minimize the connection impedance. This will help to further suppress any source of power supply generated EMI.

## SYSTEM CONSIDERATIONS

One of the major sources of radiated system EMI are the edge connectors, I/O cables, and their associated connectors.

- Use care to ensure that, not only the cables are shielded and the shield properly grounded, but that the shield totally envelopes both the cable and its connectors. The shield should seat firmly into a grounded chassis and touch the chassis a full $360^{\circ}$ around the connection. An open ended cable or an improperly grounded connector shield will be a prime suspect for out-of-spec EMI emissions and should be avoided. Use shielded coaxial cables whenever possible. If ribbon cable is preferred, shield all ribbon cables with commercially available ribbon cable shielding. Again, ensure that this shield is properly attached to the connector shield by a full $360^{\circ}$.
- In choosing or designing the enclosure for the system, minimize the number of openings in the enclosure. Since high performance logic now deals with smaller wavelengths than the older technologies, enclosure opening sizes should also be considered. Keep openings as small as possible. If openings are necessary (displays, controls, fans, etc.) there are commercially available accessories that offer good built-in EMI shielding.
- If access panels are necessary, ensure that these panels are properly sealed with some sort of shielding material (gaskets, copper brushes, etc.).
- Of course, the enclosure itself should be of a material that provides good shielding against electric fields.

## TTL-Compatible CMOS Designs Require Delta IDD Consideration

The FACT product line is comprised of two types of advanced CMOS input circuits: 'AC/'ACQ and 'ACT/'ACTQ/ 'FCT/'FCTA devices. 'ACT/'ACTQ/'FCT/'FCTA indicates an advanced CMOS device with TTL-type input thresholds for direct replacement of LS and ALS circuits. As these 'ACT/'ACTQ/'FCT/'FCTA series are used to replace TTL, the IDDT or Delta IDD specification must be considered; this spec may be confusing and misleading to the engineer unfamiliar with CMOS. In many datasheets IDDT or Delta IDD are also referred to as ICCT or Delta Icc. There are no other differences.
It is important to understand the concept of Delta IDD and how to use it within a design. First, consider where Delta $I_{D D}$ initiates. Most CMOS input structures are of the totem pole
type with an n-channel transistor in a series with a p-channel transistor as illustrated below.

TL/F/10160-52
FIGURE 3-19. CMOS Input Structure

## TTL-Compatible CMOS

## Designs Require Delta IDD Consideration (Continued)

These two transistors can be modeled as variable resistors with resistances varying according to the input voltage. The resistance of an ON transistor is approximately $4 \mathrm{k} \Omega$ while the resistance of an OFF transistor is generally greater than $500 \mathrm{M} \Omega$. When the input to this structure is at either ground or $V_{D D}$, one transistor will be ON and one will be OFF. The total series resistance of this pair will be the combination of the two individual resistances, greater than $500 \mathrm{M} \Omega$. The leakage current will then be less than $1 \mu \mathrm{~A}$. When the input is between ground and $V_{D D}$, the resistance of the $O N$ transistor will increase while the resistance of the OFF transistor will decrease. The net resistance will drop due to the much larger value of the OFF resistance. The total series resistance can be as low as $600 \Omega$. This reduction in series resistance of the input structure will cause a corresponding increase in IDD as current flows through the input structure. The following graph depicts typical IDD variance with input voltage for an 'ACT device.

FIGURE 3-20. IDD versus Input Voltage for 'ACT Devices

FIGURE 3-21. IDD versus IN for 'AC Devices

The Delta IDD specification is the increase in IDD. For each input at $V_{D D}-2.1 \mathrm{~V}$ (approx. TTL $V_{O H}$ level), the Delta $l_{D D}$ value should be added to the quiescent supply current to arrive at the circuit's worst-case static IDD value.
Fortunately, there are several factors which tend to reduce the increase in IDD per input. Most TTL devices will be able to drive FACT inputs well beyond the TTL output specification due to FACT's low input loading in a typical system. FAST logic outputs can drive 'ACT-type inputs down to 200 mV and up to 3.5 V . Additionally, the typical IDD increase per input will be less than the specified limit. As shown in the graph above, the $I_{D D}$ increase at $V_{D D}-2.1 \mathrm{~V}$ is less than $200 \mu \mathrm{~A}$ in the typical system. Experiments have shown that the IDD of an 'ACT240 series device typically increases only $200 \mu \mathrm{~A}$ when all of the inputs are connected to a FAST device instead of ground or $V_{D D}$.
It is important when designing with FACT, as with any TTLcompatible CMOS technology, that the Delta IDD specification be considered. Designers should be aware of the spec's significance and that the data book specification is a worst-case value; most systems will see values that are much less.

## Testing Advanced CMOS Devices with I/O Pins

There are more and more CMOS families becoming available which can replace TTL circuits. Although testing these new CMOS units with programs and fixtures which were developed for bipolar devices will yield acceptable results most of the time, there are some cases where this approach will cause the test engineer problems.
Such is the case with parts that have a bidirectional pin, exemplified by the ' 245 Octal Transceiver. If the proper testing methods are not followed, these types of parts may not pass those tests for $l_{D D}$ and input leakage currents, even when there is no fault with the devices.
CMOS circuits, unlike their bipolar counterparts, have static $I_{D D}$ specification orders of magnitude less than standard load currents. Most CMOS IDD specifications are usually less than $100 \mu \mathrm{~A}$. When conducting an IDD test, greater care must be taken so that other currents will not mask the actual IDD of the device. These currents are usually sourced from the inputs and outputs.
Since the static IDD requirements of CMOS devices are so low, output load currents must be prevented from masking the current load of the device during an IDD test. Even a standard $500 \Omega$ load resistor will sink 10 mA at 5 V , which is more than twice the $l_{D D}$ level being tested. Thus, most manufacturers will specify that all outputs must be unloaded during $l_{D D}$ tests.
Another area of concern is identified when considering the inputs of the device. When the input is in the transition region, IDD can be several orders of magnitude greater than the specification. When the input voltage is in the transition region, both the n -channel and the p -channel transistors in the input totem-pole structure will be slightly ON , and a conduction is created from $V_{D D}$ to ground. This conduction path

## Testing Advanced CMOS Devices with I/O Pins (Continued)

leads to the increased IDD current seen in the lod vs $\mathrm{V}_{\text {IN }}$ curve. When the input is at either rail, the input structure no longer conducts. Most $l_{D D}$ testing is done with all of the inputs tied to either $V_{D D}$ or ground. If the inputs are allowed to float, they will typically float to the middle of the transition region, and the input structure will conduct an order of magnitude more current than the actual $\mathrm{I}_{\mathrm{DD}}$ of the device under test which is being measured by the tester.
When testing the $I_{D D}$ of a CMOS ' 245 , problems can arise depending upon how the test is conducted. Note the structure of the '245's I/O pins illustrated below.

TL/F/10160-55
FIGURE 3-22. '245 I/O Structure
Each I/O pin is connected to both an input device and an output device. The pin can be viewed as having three states: input, output and output disabled. However, only two states actually exist.

The pin is either an input or an output. When testing the $l_{D D}$ of the device, the pins selected as outputs by the T/R signal must either be enabled and left open or be disabled and tied to either rail. If the output device is disabled and allowed to float, the input device will also float, and an excessive amount of current will flow from $V_{D D}$ to ground. A simple rule to follow is to treat any output which is disabled as an input. This will help insure the integrity of an IDD test.
Another area which might precipitate problems is the measurement of the leakages on I/O pins. The I/O pin internal structure is depicted below.

The pin is internally connected to both an input device and an output device; the limit for a leakage test must be the combined $I_{I_{N}}$ specification of the input and the $l_{O Z}$ specification of the output. This combined leakage test is defined as $I O Z_{T}$. For FACT devices, $\mathrm{I}_{\mathrm{N}}$ is specified at $\pm 1 \mu \mathrm{~A}$ while $\mathrm{l}_{\mathrm{OZ}}$ is specified at $\pm 5 \mu \mathrm{~A}$. Combining these gives a limit of $\pm 6 \mu \mathrm{~A}$ for I/O pins. Usually, I/O pins will show leakages that are less than the loz specification of the output alone.

TL/F/10160-56
FIGURE 3-23. I/O Pin Internal Structure

Testing CMOS circuits is no more difficult than testing their bipolar counterparts. However, there are some areas of concern that will be new to many test engineers beginning to work with CMOS. Becoming familiar with and understanding these areas of concern prior to creating a test philosophy will avert many problems that might otherwise arise later.

## Testing Disable Times of TRI-STATE ${ }^{\circledR}$ Outputs in a Transmission Line Environment

Traditionally, the disable time of a TRI-STATE buffer has been measured from the $50 \%$ point on the disable input, to the $\left(\mathrm{V}_{\mathrm{OL}}+0.3 \mathrm{~V}\right)$ or $\left(\mathrm{V}_{\mathrm{OH}}-0.3 \mathrm{~V}\right)$ point on the output. On a bench test site, the output waveform is generated by a load capacitor and a pull-up/pull-down resistor. This circuit gives an RC charge/discharge curve as shown below.

TL/F/10160-57
FIGURE 3-24. Typical Bench TRI-STATE Waveform
ATE test sites generally are unable to duplicate the bench test structure. ATE test loads differ because they are usually programmable and are situated away from the actual device. A commonly used test load is a Wheatstone bridge. The following figure illustrates the Wheatstone bridge test structure when used on the MCT 2000 test-system to duplicate the bench load.

TL/F/10160-58
FIGURE 3-25. MCT Wheatstone Bridge Test Load

## Testing Disable Times of TRI-STATE® Outputs in a Transmission Line Environment (Continued)

The voltage source provides a pull-up/pull-down voltage while the current sources provide $\mathrm{I}_{\mathrm{OH}}$ and $\mathrm{l}_{\mathrm{OL}}$. When devices with slow output slew rates are tested with the ATE load, the resultant waveforms closely approximate the bench waveform, and a high degree of correlation can be achieved. However, when devices with high output slew rates are tested, different results are observed that make correlating tester results with bench results more difficult. This difference is due to the transmission line properties of the test equipment. Most disable tests are preceded by establishing a current flow through the output structure. Typically, these currents will be between 5 mA and 20 mA . The device is then disabled, and a comparator detects when the output has risen to the ( $\mathrm{VOL}_{\mathrm{OL}}+0.3 \mathrm{~V}$ ) level or fallen to the $\left(\mathrm{V}_{\mathrm{OH}}-0.3 \mathrm{~V}\right)$ level.
Consider the situation where the connection between the device under test (DUT) and the comparator is a transmission line. Visualize the device output as a switch; the effect is easier to see. There is current flowing through the line, and then the switch is opened. At the device end, the reflection coefficient changes from 0 to 1 . This generates a current edge flowing back down the line equal to the current flowing in the line prior to the opening of the switch. This current wave will propagate down the line where it will encounter the high impedance tester load. This will cause the wave to be reflected back down the line toward the DUT. The current wave will continue to reflect in the transmission line until it reaches the voltage applied to the tester load. At this point, the current source impedance decreases and it will dissipate the current. A typical waveshape on a modern ATE is depicted in Figure 3-26.

FIGURE 3-26. Typical ATE TRI-STATE Waveform

Transmission line theory states the voltage level of this current wave is equal to the current in the line times the impedance of the line. With typical currents as low as 5 mA and impedances of $50 \Omega$ to $60 \Omega$, this voltage step can be as minimal as 250 mV . If the comparator was programmed to the disable measurement points, it would be looking for a step of approximately 575 mV at $5.5 \mathrm{~V} \mathrm{~V}_{\mathrm{DD}}$. Three reflections of the current pulse would be required before the comparator would detect the level. It is this added delay time caused by the transmission line environment of the ATE that may cause parts to fail customer's incoming tests, even though the device meets specifications. The figure below graphically shows this stepout.
Point A represents the typical $50 \%$ measurement point on tester driven waveforms. Point B reprsents the point at which the delay time would be measured on a bench test fixture. Point $C$ represents where the delay time could be measured on ATE fixtures. The delay time measured on the ATE fixture can vary from the bench measured delay time to some greater value, depending upon the voltage level that the tester is set. If the voltage level of the tester is close to voltage levels of the plateaus, the results may become nonrepeatable.

TL/F/10160-60
FIGURE 3-27. Measurement Stepout

## Understanding Latch-Up in Advanced CMOS Logic

Latch-up has long been a bane to CMOS IC applications; its occurence and theory have been the subjects of numerous studies and articles. The applications engineer and systems designer, however, are not so much concerned with the theory and modeling of latch-up as they are with the consequences of latch-up and what has been done by the device designer and process engineer to render ICs resistant to latch-up.
Of equal interest are those precautions, if any, which must be observed to limit the liability of designs to latch-up.

## WHAT IS LATCH-UP?

Latch-up is a failure mechanism of CMOS (and bipolar) integrated circuits characterized by excessive current drain coupled with functional failure, parametric failure and/or device destruction. It may be a temporary condition that terminates upon removal of the exciting stimulus, a catastrophic condition that requires the shutdown of the system to clear or a fatal condition that requires replacement of damaged parts. Regardless of the severity of the condition, latch-up is an undesirable but controllable phenomenon. In many cases, latch-up is avoidable.
The cause of the latch-up exists in all junction-isolated or bulk CMOS processes: parasitic PNPN paths. Figure 1, a basic CMOS cross section, shows the parasitic NPN and PNP bipolar transistors which most frequently participate in latch-up. The $\mathrm{P}+$ sources and drains of the P -channel MOS devices act as the emitters (and sometimes collectors) of lateral PNP devices; the N -substrate is the base of this device and collector of a vertical NPN device. The P-well acts as the collector of the PNP and the base of the NPN. Finally, the N+ sources and drains of the $N$-channel MOS devices serve as the emitter of the NPN. The substrate is normally connected to $\mathrm{V}_{\mathrm{CC}}$, the most positive circuit voltage, via an $N+$ diffusion tap while the P-well is terminated at Gnd, the most negative circuit voltage, through a $\mathrm{P}+$ diffusion. These power supply connections involve bulk or spreading resistance to all points of the substrate and P -well.
Normally, only a small leakage current flows between the substrate and P -well causing only a minute bias to be built up across the bulk due to the resistivity of the material. In
this case the depletion layer formed around the reverse-biased PN junction between P -well and the substrate supports the majority of the $\mathrm{V}_{\mathrm{CC}}$-Gnd voltage drop. As long as the MOS source and drain junctions remain reverse-biased, CMOS is well behaved. In the presence of intense ionizing radiation, thermal or over-voltage stress, however, current can be injected into the PNP emitter-base junction, forwardbiasing it and causing current to flow through the substrate and into the P-well. At this point, the NPN device turns on, increasing the base drive to the PNP. The circuit next enters a regenerative phase and begins to draw significant current from the external network thus causing most of the undesirable consequences of latch-up. Once established, a latchup site, through the fields generated by the currents being conducted, may trigger similar action in both elements of the IC.

## WHAT TO DO

As might be expected, latch-up is highly dependent on the characteristics of the bipolar devices involved in the latchup loop. Device current gains, emitter efficiencies, minority carrier life times and the degree of NPN-PNP circuit coupling are all important factors relating to both the sensitivity of the particular latch-up device and to the severity of the failure once it has been excited. Layout geometry and process both contribute significantly to these parameters; CMOS, like other technologies, has been shrunk to provide more function per unit area, increasing susceptibility to latch-up. All major CMOS vendors have upgraded their processes and/or design rules to compensate for this increased susceptibility, some with more success than others. The lateral PNP is typically the weak link in the latch-up loop. As such, various devices can be exploited toward reducing the effectiveness of the PNP to participate in latchup. Guard banding, device placement, the installation of pseudo-collectors between the P-channel devices and the $P$-well, and the use of a low resistivity substrate under an epitaxial layer are a few of the IC design tactics now being practiced to reduce the current gain or to control the action of the lateral PNP structures in state-of-the-art CMOS devices.

TL/F/10192-1

Vendors of CMOS ICs have always been aware of the latchup phenomenon and have considerably improved their designs and processes to reduce the danger of latch-up occuring under normal usage. Abnormal applications and misuse of CMOS ICs may still pose problems that the CMOS vendor has little control over. Hence, CMOS users must be aware of what they are doing and those measures which must be taken to reduce the susceptibility to latch-up. The use of CMOS at or beyond its rated maximum voltage range and the presence of inductive transients are applications-related situations which can trigger latch-up. Environment, including thermal stress, poorly regulated or noisy supplies and radiation incidence can also contribute to or cause latch-up. The system engineer must consider these situations when using CMOS in designs.
While latch-up is generally recognized as resulting from regenerative switching along a PNPN path, many designers incorrectly assume that this regenerative action places the device in a state that can only be recovered from if the system is powered down. The fact is that there is probably an equal, if not greater, chance that the regenerative switching, when encountered, will be non-sustaining (the condition, more accurately referred to as current amplification, will disappear when the triggering stimulus is removed); over-voltage applied to properly designed input protection networks is one example of controlled current amplification. For sustained latch-up to occur, the regeneration loop must have sufficient gain and the power source must be able to supply a minimum current. From this we can see that cur-rent-limited power supplies might be used to recover from or reduce the effects of latch-up. Another method uses cur-rent-limiting series resistors in the power connections of offending ICs in conjunction with storage capacitors shunting the devices. Normal switching current will be drawn from the capacitors while DC current will be limited by the resistors.
In the loop of positive current feedback formed by the parasitic PNP and NPN transistors of the latch-up structures, regenerative switching may result if sufficient loop gain is available. One must remember, though, that three conditions are necessary for latch-up to occur.

1) both parasitic bipolars must be biased into the active state;
2) the product of the parasitic bipolar transistor current gains (Bnpn•Bpnp) must be sufficient to allow regeneration, i.e., greater than or equal to one;
3) the terminal network must be capable of supplying a current greater than the holding current required by the PNPN path. In processes utilizing an epitaxial silicon, this current is usually in excess of 1 A .
If any of these conditions is not met both during the initiation and in the steady state, then the latch-up condition is either non-sustaining or cannot be initiated. If the current to the latched structure is not limited, permanent damage may result. Again, any means to prevent any of these conditions from being satisfied will protect the circuit from exhibiting sustained latch-up.
The prevention of biasing the bipolars into the active region and the limiting of the current which may be supplied by the network are the two factors which system designers have under their control. Many of the protective measures long exercised in discrete and TTL designs may also be applied to CMOS designs to reduce susceptibility and prevent damage to these systems. Diode clamping of inductive loads, signal and supply level regulation, and sharing of large DC loads by several devices with suitable series limiting resis-
tors to distribute thermal stress over a larger area or multiple ICs are all positive-preventive measures to exploit.
While we have been considering the CMOS device in a generic manner, there are two primary structures used in all CMOS ICs which have latch-up paths associated with them; these are the inverter or gate and the transmission switch. Both structures may be susceptible under the right conditions. While the CMOS inverter can exhibit latch-up independent of circuit configuration, the transmission switch usually has lower holding current, and thus, a lower threshold for latch-up, but is dependent on its external connections for latch-up to occur. Figure 2 shows the lumped equivalent circuit of the inverter. Notice the shunting resistors across the base-emitter junctions of the bipolar transistors: these resistors divert base drive from the bipolars and as a result increase both the trigger current and holding current levels required for the structures to participate in latch-up. A further increase in these current levels can be achieved by further decreasing the shunt resistance. Diffusing all active components into an epitaxial silicon, under which would lie a substrate of substantially less resistivity, will have a dramatic effect on decreasing the shunt resistance, therefore increasing the trigger current and holding current levels required for latch-up.

## THE CIRCUIT CONNECTION

As we have seen above, the external circuit connections are regular participants in the latch-up process. The current for latch-up comes from these connections and often the triggering mechanism is external to the latching device. All three classes of external connections (power, input and output) are important in latch-up. We will now look at how these connections relate to this process.
Current injection through the power terminals when the power supply voltage is beyond the maximum rated for the CMOS device can directly cause latch-up through base collector leakage or breakdown mechanisms. One aspect of high power supply voltages that is not often recognized is the effect of field-aiding lateral currents under the emitters of the PNP devices. This can effect a significant increase in the beta of these devices, making internally trigger latch-up much more prevalent. Again, the warning to the the system designer is to avoid using CMOS at maximum rated supply voltages unless precautions are taken to insure latch-up is unlikely or is at least acceptable and recoverable. Switching transients coupled onto power lines has become a problem

TL/F/10192-2
FIGURE 2. CMOS Inverter with Parasitic Bipolars
now that CMOS has become a high-speed logic technology. Attention to power supply decoupling is now a necessity when designing with high-speed CMOS. Of course, CMOS processes incorporating an epitaxial silicon over a substrate of very low resistivity is less prone to latch-up under these conditions. These recommended precautions should be taken just the same.
Latch-up involving input terminals, next to gate oxide rupture, used to be one of the most common failure mechanisms of CMOS. Transients exceeding the power supply routinely caused either or both of these effects to occur. Fortunately, CMOS vendors have learned to make better input protection networks and have learned that proper placement of these components with respect to the rest of the chip circuitry is necessary to reduce susceptibility to latch-up. The system designer should review foreign input signals to CMOS systems and take precautions necessary to limit the severity of over/undershoot from these sources. Measures which could be used to reduce the possibility of latch-up induced by input signals are: proper termination of transmission lines driving CMOS, series current limiting resistors, AC coupling with DC restoration to the CMOS supplies, and the addition of Schottky diode clamps to the CMOS power rails. As an additional measure there are several CMOS circuits which have input protection networks that can handle overvoltage in one direction or the other and which are specifically designed to act as interface circuits between other logic families and CMOS. Judicious application of these will also aid in suppressing any tendencies of CMOS systems to latch-up.
Finally, attention to CMOS outputs, their loading and the stresses applied to them will also enable the designer to generate latch-up free systems. Historically, output terminals of CMOS have been least likely to cause latch-up though they can participate in latch-up once it is initiated. The normal mode of failure in this respect is, again, the application of voltages beyond the CMOS supplies or the maximum limit for the devices though excessive current has also been linked to latch-up failure at elevated temperatures. Inductive surges and transmission line reflections are the most likely sources of output latch-up in CMOS and should be attended to in the most applicable method, i.e., by clamping, termination or through dissipative measures.

## WHAT WE HAVE DONE

National Semiconductor, as an important supplier of advanced CMOS to all segments of the industry, has made a commitment to provide IC designs which make use of state-of-the-art latch-up suppression techniques in an effort to support its customers before they need support. The three most important actions which we have taken to guard our customers from latch-up are in the areas of layout, power distribution and process design. These techniques, along with recognized good design practice, yield a product line that lives up to the intent of an advanced CMOS family. In brief review, National Semiconductor's attack on latch-up is summarized in the following.

## Latch-Up Protection Geometries

Every FACTTM IC employs special geometries to isolate every input protection device and every output from active areas on the chip. In this way, structures which would normally participate in latch-up loops are decoupled and are thus less troublesome. All devices are scrutinized for potential latch-up sites and are protected by similar geometries where any risk is significant.

## Power Distribution

Careful attention to on-chip power distribution and enhanced termination of P-wells and substrate is used by Na tional Semiconductor to improve latch-up resistance. Our double metal process affords the advantage in maintaining low impedance distribution of power and ground potentials over the entire chip; the potential gradient-caused fields which often induce or enhance latch-up are thus minimized while functional performance is enhanced by cleaner onchip power supplies.

## Process Design

By design, the FACT process is better both in low latch-up susceptibility and in enhanced device performance. The most significant advancement of the FACT process has been the incorporation of an epitaxial silicon layer. Figure 3 illustrates a modified version of Figure 1 , utilizing an epitaxial layer of silicon to contain all of the active components of the CMOS circuit. This epitaxial layer allows the use of a separate layer of substrate silicon, of a resistivity some three orders of magnitude lower than the epitaxial layer. The effect is also modeled in Figure 3.
As illustrated, the resistivity of the epitaxial silicon, $R_{1}$, is on the order of 6 ohm -cm to $10 \mathrm{ohm}-\mathrm{cm}$. The underlying substrate resistivity, $R_{2}$, is as low as 0.008 ohm-cm to $0.025 \mathrm{ohm}-\mathrm{cm}$. The result is a parallel combination of resistivities, $R_{1}$ and $R_{2}$, that is equivalent to $R_{2}$. What has now happened is that the gain of the parasitic PNP-NPN circuit has been dramatically slashed. Under the same latch-up conditions described earlier, the introduction of the low resistivity substrate now means that at least 10 times more current is needed to trigger the parasitic PNP-NPN combination.
The active components within the epitaxial layer maintain the same performance characteristics as those of the active area illustrated in the non-epitaxial CMOS circuit of Figure 1. Therefore the introduction of the epitaxial layer to the FACT process does not reduce any AC, DC, functional or ESD performance. However, what we have is an advanced CMOS logic family that is now virtually latch-up immune.
Thus, through innovative and careful layout, attention to eliminating circuit situations which could be latch-up prone and by careful selection and maintenance of our advanced CMOS process, FACT sets the standard for latch-up resistance.

FIGURE 3

## Terminations for Advanced CMOS Logic

National Semiconductor<br>Application Note 610

## INTRODUCTION

Advanced CMOS logic such as National Semiconductor's FACT (Fairchild Advanced CMOS Technology) logic, has extended CMOS performance to the level of advanced bipolar technologies. While high-performance design rules that are currently utilized for bipolar designs are also applicable to CMOS, power consumption becomes a new area of concern in high-performance system designs.
One advantage of using advanced CMOS logic is its low power consumption. However careless circuit design can increase power consumption, possibly by several orders of magnitude. A simple FACT gate typically consumes $625 \mu \mathrm{~W} / \mathrm{MHz}$ of power; at 10 MHz , this translates to 6.25 mW . A $50 \Omega$ parallel termination on the line will use over 361 mW with a $50 \%$ duty cycle.
The use of high-performance system board design guidelines is important when designing with advanced CMOS families. Because of advanced CMOS logic edge rates (less than $3 \mathrm{~ns}-4 \mathrm{~ns}$ ), many signal traces will exhibit transmission line characteristics.

A PCB trace begins to act as a transmission line when the propagation delay ( $t_{\mathrm{pd}}$ ) across the trace approaches one third of the driver's edge rate. For advanced CMOS, lines as short as 6 to 8 inches may exhibit these effects. This rule
encompasses many traces on a standard PCB. With older CMOS technologies which have lower edge rates, this critical length is much longer: 18 inches for 74 HC and 5 feet for CD4000 series and 74C devices. A transmission line terminating into a mismatched impedance could result in transient noise which adversely affects signal integrity.
The FACT family also features guaranteed line driving capability. The IOLD/IOHD specifications guarantee that a FACT device can drive incident wave voltage steps into line impedances as low as $50 \Omega$. The lold specifications do not guarantee incident wave switching into bipolar level inputs since the input low thresholds are 500 mV to 850 mV lower than CMOS. Due to the relatively linear behavior of the outputs below 1V, CMOS devices can drive incident voltages, adequate for bipolar inputs, into line impedances as low as $80 \Omega$. For line impedances lower than $80 \Omega$, termination can be used to provide adequate input levels. Thus besides reducing noise transients, terminations could also be used to interface between devices from different technologies.
Five possible termination schemes are presented with their impact on power dissipation and noise reduction. Figure 1 illustrates these schemes.

FIGURE 1. Termination Schemes

## NO TERMINATION

No termination is the lowest cost option and features the easiest design. For line lengths 8 inches or less, this is often the best choice. For lines longer than 8 inches, transmission line effects (line delays and ringing) may exist. Figure 2 illustrates the effect of a FACT device driving a 3 -foot open-ended coaxial line. Clamp diodes at the inputs of most logic devices tend to reduce the ringing and overshoots. Often, these clamp diodes are sufficient to insure reliable system operation. Figure 3 illustrates the impact of these diodes on the same 3 -foot coaxial line. However, it is not uncommon to find logic devices like DRAMs, D-to-A converters and PLDs, that have no input clamp diodes.

TL/F/10218-2
FIGURE 2. Transmission Line Effects FACT Driving 3 Foot Open-Ended Coax

TL/F/10218-3
FIGURE 3. Effects of Input Clamp Diodes FACT Driving FACT with no Termination

## PARALLEL TERMINATION

Parallel termination provides an AC and DC current path back to the power supply for switching currents. While it effectively reduces ringing (Figure 4), the DC path to ground or to $\mathrm{V}_{\mathrm{CC}}$ will dissipate power. The power consumption for this type of a termination scheme has some important implications. For proper impedance matching the value of this terminating resistor should be equal to the characteristic impedance of the line.

TL/F/10218-4
FIGURE 4. FACT Driving FACT with Parallel Termination
The DC component to the power consumption is a function of the signal duty cycle. Signals with lower duty cycles will dissipate less DC power. Since the load seen by the driving device is resistive, not capacitive, load capacitance does not affect power consumption. Therefore, parallel termination dissipates less AC power. Because of this lower AC power at high frequencies, parallel terminations may consume less power than no termination. Depending upon the load capacitance, signal duty cycle, and line impedance, this frequency can be as low as 40 MHz .
There are drawbacks associated with parallel termination. The maximum DC current allowed into or out of any FACT output is 50 mA . This limits the allowable resistor values to greater than $100 \Omega$. Even though this ringing may not be excessive, imperfect impedance matching may cause ringing on lines with an impedance less than $100 \Omega$. However, because the high-power dissipation of this termination scheme negates the advantages of advanced CMOS logic, this is not an intended advanced CMOS application.
Parallel termination tends to unbalance CMOS outputs. Using a resistor to ground, the CMOS device will achieve a 0.0 V output low voltage ( $\mathrm{V}_{\mathrm{OL}}$ ). But due to the high DC load in the logic HIGH state, the output high voltage $\left(\mathrm{V}_{\mathrm{OH}}\right)$ will be degraded (Figure 4). This degraded high level output will be above the input high voltage $\left(V_{\mid H}\right)$ of both CMOS and bipolar inputs due to the guaranteed dynamic current (VOHD) specifications ( $75 \mathrm{~mA} @ 3.85 \mathrm{~V}, \mathrm{~V}_{\mathrm{CC}}=5.5 \mathrm{~V}$ ). This lower $\mathrm{V}_{\mathrm{OH}}$ level may cause an increase in ICC if the driven device is CMOS; however, this increase should be minimal.

## THEVENIN TERMINATION

Thevenin termination is similar to parallel termination, except that both pull-up and pull-down resistors are used. Power consumptions are also similar for both of these schemes. The difference is that the DC power consumption is a function of duty cycle and resistor ratios. If the resistors are matched, DC power consumption is not dependent upon duty cycle. One advantage Thevenin termination has over parallel termination is that lines with impedances as low as $50 \Omega$ can be terminated in their characteristic impedances. For proper impedance matching, the equivalent thevenin resistance should be the same as the line characteristic impedance.
Thevenin termination does not create unbalanced CMOS outputs, although it reduces the output swing (Figure 5). This limited output swing may increase current consumption in a driven CMOS device however this increase is minimal.

FIGURE 5. FACT Driving FACT with Thevenin Termination
Busses using Thevenin termination should not be left floating. A floating bus level is determined by the ratio of the resistors. If this level is close to any input threshold, output oscillations and ICC increase may occur. If the bus must be left floating, the resistor ratio should be chosen so that an adequate noise margin is insured. The bus could be left floating by either turning off the driver or by placing the bus in a high impedance state.
Other terminations which do not introduce DC current paths may be more suitable to CMOS systems. These include series and $A C$ parallel terminations.

## SERIES TERMINATION

Series termination works by limiting the current that is put into a line. While other termination circuits dissipate extra power, series termination reduces power consumption and dissipates less energy than no termination. This is a recommended termination scheme for the FACT family because of its low power dissipation.

Series termination assumes that any voltage step driven into a transmission line will double at the receiver. Therefore, the initial voltage step driven into the line is one-half of the receiver input voltage. The resistor value can be computed by $R_{S}=Z_{O}-R_{D}$, where $R_{S}$ is the resistor value, $Z_{O}$ is the line impedance and $R_{D}$ is the driver resistance. Figure 6 illustrates the waveforms associated with series termination.

FIGURE 6. FACT Driving FACT with Series Termination
While the device output produces a full output step, only half of that is driven into the line. At the receiver end, the edge doubles, thus recreating the full output swing. The initial step then reflects back, fixing the full output voltage applied on the entire line. A voltage plateau is created at the input to the line whose width will be twice the line $\mathrm{t}_{\mathrm{pd}}$.
Series termination is well suited for lines with a single driver receiver pair. Series termination limits the initial voltage step, which offers several benefits: reduced power consumption and decreased cross-coupled radiated noise.
One possible drawback to series termination is that any other receiver located near the driver will see the voltage plateau. Because the plateau level may be very close to the typical CMOS threshold ( $50 \%$ of.$V_{C C}$ ), any such input could see multiple input switching. Combinatorial outputs may oscillate, or clocked inputs may experience multiple clocking.
One solution is to choose the resistor value that keeps the initial voltage step away from the input thresholds. Larger resistor values will require one or more reflections to settle out, while still maintaining valid $V_{I N}$ levels at the inputs. Smaller values will generate overshoot and undershoot.

## AC PARALLEL TERMINATION

AC Parallel termination is another technique which blocks the DC path to ground. A capacitor in series with the parallel termination resistor blocks the DC path, while maintaining the $A C$ path. This is a highly recommended termination scheme for the FACT family because of its negligible DC power consumption.

After the initial voltage step, the capacitor will charge up to the rail voltage at a rate determined by the RC time constant of the circuit (Figure 7).

TL/F/10218-7
FIGURE 7. FACT Driving FACT with AC Termination
The capacitor value needs to be carefully determined. If the RC time constant is too small, the RC circuit will act as an edge generator and will create overshooting and undershooting. While increasing the capacitor reduces overshoot, it also increases power consumption. As a rule, the RC time constant should be greater than 3 times the line delay.
When driving TTL-level inputs, the same threshold concerns arise as with no termination. The lold current specifications guarantee incident wave switching into CMOS inputs on line impedances as low as $50 \Omega$. For TTL-level inputs, this minimum line impedance rises to $80 \Omega$. When the line impedance is less than $80 \Omega$, a termination value greater than the line impedance will increase the amplitude of the initial voltage step; this can be used to guarantee incident wave switching into both TTL and CMOS-level inputs. Large resistor values will cause ringing on the line, but the amplitude should be small and not present any problems.
At lower frequencies, this termination capacitance increases the total signal trace impedance; therefore, it also increases the slope of the power consumption curve. At higher frequencies, the capacitor is unable to fully charge or discharge, and the slope of the curve falls off. At very high frequencies, $A C$ parallel termination acts like a parallel resistor tied to an intermediate voltage supply, with the voltage level determined by the signal duty cycle. The slope of the power consumption curve is dependent on $\mathrm{C}_{\text {PD }}$ (Power dissipation capacitance) of the device. The power crossover point between no termination and AC termination may be as low as 15 MHz , depending upon the system capacitive loading and the signals' duty cycle.

## POWER CONSUMPTION

The use of one of these termination schemes will affect the power consumption of the system. Power consumption depends upon the circuit used, signal frequency, device and signal trace loads, signal duty cycle, system $\mathrm{V}_{\mathrm{CC}}$ and component values.
Figure 8 shows the power consumption of each type of termination circuit over a frequency range. For low frequency signals, termination circuits without DC components will usually use less power (no termination, series termination and $A C$ parallel termination). At higher frequencies, parallel termination or AC termination may consume less power because of lower AC power consumption. The AC power consumption of these two termination schemes is a function of the device $C_{P D}$, while the AC power consumption of the other termination schemes is a function of both the device $C_{P D}$ and the system capacitive loading $\left(C_{L}\right)$. The $A C$ power consumption of $A C$ parallel termination at low frequencies also includes the termination capacitance. The signal used for these curves has a $50 \%$ duty cycle. The DC power consumption of the parallel termination will drop as duty cycles drops. For very low duty cycle signals, this scheme may consume the least amount of power.
For low frequencies, the slope of the AC parallel termination curve is greater than any other. This is because it is a function of the device $C_{P D}$, the capacitive loading $\left(C_{L}\right)$, and the termination capacitance $\left(C_{T}\right)$. But at higher frequencies where the pulse width is less than the RC time constant, the slope drops off. At some frequency less than that of parallel termination, $A C$ parallel termination will use less power than using no termination. At some higher frequency, this circuit uses less power than series termination.

## SUMMARY

With new advanced CMOS logic families, power consumption has become an important issue in high-performance systems. Because of the need to use termination, system designers need to be aware of how these circuits affect the power consumption of their systems. The power consumption of the termination scheme will vary, depending upon frequency, duty cycle, line impedance, loading and other factors (Figure 8).

FIGURE 8. Power Consumption

Power consumption is not the only concern when choosing a termination circuit. Part-count and board space are also important concerns. It is up to system designers to choose which, if any, termination circuit is best suited to their circuit. Table I shows the recommended values for the various termination schemes. It is highly recommended that the designer use these values as a starting point and adapt it for the most feasible and optimum results.

TABLE I. Recommended Termination Values

- Parallel:

Resistor $=Z_{O}$

- Thevenin: $\quad$ Resistor $=2 \times Z_{O}$
- Series:

Resistor $=Z_{\mathrm{O}}-\mathrm{Z}_{\text {OUT }}$

- $A C$ :

Resistor $=Z_{\mathrm{O}}$
Capacitor $=C \geq \frac{3 \text { td }}{Z_{O}}$

- Active:

Resistor $=2 \times \mathrm{Z}_{0}$

## Understanding and Minimizing Ground Bounce

## National Semiconductor Application Note 640

## DEFINING GROUND BOUNCE

As edge rates and drive capability increase in advanced logic families, the effects of intrinsic electrical characteristics become more pronounced. One of these intrinsic electrical characteristics is the inductance found in all leadframe materials.

Figure 1a shows a simple circuit model for a CMOS device in a leadframe driving a standard test load. The inductor L1 represents the intrinsic inductance in the ground lead of the package; inductor L2 represents the intrinsic inductance in the power lead of the package; inductor L3 represents the intrinsic inductance in the output lead of the package; the resistor R1 represents the output impedance of the device output, and the capacitor and resistor $C_{L}$ and $R_{L}$ represent the standard test load on the output of the device.
The three waveforms shown in Figures $1 b, c$, and $d$ depict how ground bounce is generated. The first waveform shows the voltage $(\mathrm{V})$ across the load as it is switched from a logic HIGH to a logic LOW. The output slew rate is dependent upon the characteristics of the output transistor, and the inductors L1 and L3, and $C_{L}$, the load capacitance. The second waveform shows the current that is generated as the capacitor discharges [ $\left[=-C_{L} \bullet d V / d t\right)$ ]. The third waveform shows the voltage that is induced across the inductance in the ground lead due to the changing currents $\left[\mathrm{V}_{\mathrm{GB}}=\mathrm{L} \bullet(\mathrm{dl} / \mathrm{dt})\right]$.
While these diagrams and figures are useful in explaining the origins of ground bounce, they are highly theoretical and idealistic. There are many second and third order effects which would need to be considered for a complete theoretical analysis. Considering these effects, though, would lead to highly complex second and third order differential equations which are difficult to solve. The purpose of this application note is to develop a fundamental understanding of ground bounce and to provide a useful set of design guide-
board layout than older, slower technologies. The resulting advantages-low power and high performance-greatly outweigh these considerations.

d. $\mathbf{V}_{\mathrm{GB}}=\mathrm{L} \bullet(\mathrm{dl} / \mathrm{dt})$

FIGURE 1. Ground Bounce Circuit Model
lines. Therefore, we will avoid these lengthy and complex theoretical discussions wherever possible.
In order to change the output from a HIGH to a LOW, current must flow to discharge the load capacitance. This current, as it changes, causes a voltage to be generated across the inductances in the circuit. The formula for the voltage across an inductor is $\mathrm{V}=\mathrm{L} \bullet(\mathrm{dl} / \mathrm{dt})$. This induced voltage creates what is known as ground bounce. Because the inductor is between the external system ground and the internal device ground, the induced voltage causes the internal ground to be at a different potential than the external ground. This shift in potential causes the device inputs and outputs to behave differently than expected because they are referenced to the internal device ground, while the devices which are either driving into the inputs or being driven by the outputs are referenced to the external system ground. External to the device, ground bounce causes input thresholds to shift and output levels to change. This situation is very similar to that of large systems where voltages can develop across expansive ground networks.

## OTHER CAUSES OF GROUND BOUNCE

Although this discussion is limited to ground bounce generated during HIGH-to-LOW transitions, it should be noted that the ground bounce is also generated during LOW-toHIGH transitions. This ground bounce is created by the large gate capacitances associated with the output transistors on the die. Because these gate capacitances are larger than the gate capacitances of earlier-stage transistors, more current is generated when they switch. The output buffer stages of CMOS devices are inverters; thus their inputs are switching HIGH-to-LOW when their outputs are switching LOW-to-HIGH. It is the currents associated with switching these inputs to the output transistors that generate ground bounce when the outputs switch LOW-to-HIGH. This LOW-to-HIGH ground bounce has a much smaller amplitude and therefore does not present the same concern.
We should also note that everything discussed here concerning ground bounce can be applied to the opposite effect, $V_{D D}$ bounce. $V_{D D}$ bounce is the inverse of ground bounce. As one would expect, there is an intrinsic inductance in the $V_{D D}$ lead as well as the ground lead. The internal $V_{D D}$ potential will collapse toward ground at the beginning of a LOW-to-HIGH transition and then bounce above the external $\mathrm{V}_{\mathrm{DD}}$ potential at the end of the transition.

TL/F/10232-5

- $V_{D D}$ bounce (droop) is the voltage drop across the package
- Inductance (to $V_{D D}$ ) is caused by charging load capacitances
- $V_{D D}$ bounce is less of a concern than ground bounce because TTL-level inputs have greater high noise immunity

FIGURE 2. Ground Bounce/VDD Bounce
In addition, $\mathrm{V}_{\mathrm{DD}}$ bounce is generated during HIGH-to-LOW transitions for the same reasons that ground bounce is generated during LOW-to-HIGH transitions.

We will not discuss $V_{D D}$ bounce in this application note because its effects parallel those of ground bounce, and the system problems of $V_{D D}$ bounce are typically of less concern than ground bounce. This is because TTL inputs have a greater input high noise margin that input low noise margin. For CMOS driving TTL, the input high noise margin approaches 3.5 V , and for CMOS driving CMOS, the input high noise margin approaches 2.5 V . In either case, the input high noise margin is 3 to 5 times greater than any expected $V_{D D}$ bounce.

## CONTRIBUTING FACTORS OF GROUND BOUNCE

While our circuit diagrams shown above are useful for explaining the origins of ground bounce, they are too idealistic to be used for modeling. In the real world, there are many other variables which affect the actual shape and amplitude of the induced voltage. To develop an accurate model, the resistor must be replaced with a model of the actual transistor. In addition, the period where the transistors are turning on and off would need to be taken into account. Including these variables, plus others, would lead to highly complex differential equations that are nearly impossible to solve except by the most advanced computer programs. Since theoretical analysis of ground bounce is difficult to perform, we will use empirical data to develop an understanding of ground bounce and how it is effected.
There are several factors which affect ground bounce: the number of outputs switching simultaneously; the location of the output pin; the location and type of load on the line; the $V_{D D}$ voltage; the device technology; and the output and ground inductances. Each of these factors play a critical role in the generation of ground bounce.

## GROUND BOUNCE DEMONSTRATION BOARD

In order to evaluate ground bounce and the factors which affect it, Fairchild designed a board which allowed side-byside evaluation of ground bounce under varying conditions.
Figure 3 shows the functional block diagram of the board. A counter generates the changing data lines by counting from 0 to 127. The counter can also be configured to count down from 127 to 0 so that $V_{D D}$ bounce may be evaluated. This changing data is clocked into an 'AC374 and then passed into both another 'AC374 and an 'AC244. This was done for two reasons.
First, the noise generated by the first 'AC374 represents gound bounce generated by a lightly-loaded circuit. Secondly, being able to choose between either the 'AC374 or the 'AC244 to drive the system bus allows us to evaluate both devices under heavy load conditions. The quiet output from these two devices drives a line that is connected to the clock inputs of eight '74 D-type flip-flops and two inverter inputs. Each flip-flop is configured so that if a valid clock was encountered, the $Q$ output will go from a " 0 " to a " 1 "; each flip-flop acts as qlitch catcher, detecting any ground bounce noise which violates the flip-flop clock thresholds. Devices from several common logic families are connected to this quiet output so that the effect on different technologies can be evaluated.
The seven other outputs of the 'AC374 or the 'AC244 drive a 7-bit data bus. This data bus is loaded with fourteen devices, which represents a typical heavily-loaded system bus and allows us to evaluate ground bounce under these conditions.

TL/F/10232-7
FIGURE 4. Critical Signal Paths

Each device on the bus is configured equivalent to a standard test fixture. Conditions such as output loading, load placement, power supply voltage, and quiet output pin location were varied to compare ground bounce under different conditions. Also, some device locations were populated with different device types and devices from other logic families to evaluate ground bounce across technologies.
Table I lists the important electrical characteristics for the critical signal paths. Figure 4 shows the physical layout of the board and the critical paths. This board was used to generate the data and waveforms presented in this application note unless otherwise noted.

## LEAD INDUCTANCE

The impact of the ground inductance on ground bounce seems to be obvious. For a given $\mathrm{dl} / \mathrm{dt}$ value, the greater the inductance, the greater the ground bounce. While this would imply that reducing the ground inductance should reduce the ground bounce, this is not always the case. The explanation is fairly straightforward.
Ground bounce tends to limit the available AC current in CMOS outputs by reducing the voltage across the output impedance, and therefore, reduces the current that will flow. When the ground lead inductance is reduced, a corresponding increase in the output edge rate of the device occurs. This is due to the fact that by reducing the inductance in the ground lead we have increased the available AC current. This greater dl/dt tends to reduce any improvement that the reduced ground inductance may have generated.
National tested FACT to investigate the effect of ground inductance on ground bounce. This was accomplished by assembling die from the same manufacturing lot in plastic DIPs; some were assembled using the standard pinout and some were assembled with the ground and power pads connected to the center pins. When the data was analyzed, it was found that the die assembled with center pin $V_{D D}$ and ground averaged approximately $10 \%-15 \%$ less ground bounce than the die assembled with the standard pinouts. Along with the small reduction in ground bounce, they also exhibited somewhat faster edge rates with corresponding decreases in propagation delays.

## OTHER PACKAGES

The inductance in the ground lead is not the only inductance in the package; all of the output pins have an associated inductance. The inductances in the outputs also contribute to ground bounce, especially any oscillatory effects. While just reducing the ground or $V_{D D}$ does not significantly reduce ground bounce, reducing the inductance in both the power leads and the outputs does reduce ground bounce.
Figure 5 outlines the effect that packaging has on ground bounce. In order to make the comparison as valid as possible, die from the same wafer were used. This was necessary because the effect of process variations on ground bounce is greater than the effect of packaging. It can be seen that packages with smaller power and signal lead inductances tend to reduce ground bounce. It is important to note that the difference between CDIP and LCC package ground lead inductance is approximately one order of magnitude ( 20 nH versus 2 nH ), yet the difference in ground bounce is less than $35 \%$.

TL/F/10232-8
FIGURE 5. Noise vs Package Configuration
Reducing the ground lead inductance is not "the" solution to ground bounce problems. While a small reduction in ground bounce can be realized, additional problems, like increased crosstalk, may occur. A better solution is to reduce the inductance in all leads. Smaller packages, such as SOIC and LCC/PLCC packages, do reduce ground bounce over both standard and center-VDD/ground-pinned DIP packages.

## NUMBER OF OUTPUTS SWITCHING

The number of outputs switching simultaneously affects the amplitude of ground bounce. For a simple model, treat the output impedances of each active output as resistors and inductors in parallel. For resistors of equal value in parallel, the formula for the net resistance is $R / n$, where $R$ is the output impedance of each transistor, and $n$ is the number of resistors. Therefore, as more outputs switch at the same time, the output resistance is reduced and more ground bounce will be generated.
Again, it is very difficult to model this effect so we will rely on empirical results for our analysis. Figure 6 illustrates the effect of increasing the number of outputs switching at the same time. We can see that as the number goes up, the amplitude and duration of the ground bounce pulse also increases. Therefore, devices that have fewer outputs will have less ground bounce.

TL/F/10232-9
FIGURE 6. Number of Outputs Switching

Figure 7 shows the ground bounce generated by an 'AC157 when three of the four outputs are switching with standard test loads. Here we see only 475 mV of noise on the worstcase pin (pin furthest from the ground pin). This amplitude of ground bounce is not what we would expect in an actual system. As we will discuss later, a test fixture lumped load creates much more ground bounce than distributed system loads.

## OUTPUT LOAD

The type and value of the output loading is one of the major variables that affect the amplitude of the ground bounce. Figures 8, 9 and 10 show the effects of varying the load capacitance in a standard test fixture.
In Figure 8, the ground bounce amplitude peaks for a load capacitance of approximately $60-70 \mathrm{pF}$, and then drops off as the capacitance is increased. This drop off is caused by the filtering effect of the larger capacitors.
For Figure 9, only the load capacitors on the active outputs were varied. The load on the quiet output was maintained at 50 pF . The amplitude of the ground bounce amplitude increased with increased capacitive loading. However, the slope of the curve drops off as the capacitance increases. This is due to the amount of energy that is discharged from the capacitor during the time that the output transistor is turning on.

FIGURE 7. 'AC157 Quiet Output Noise

Smaller capacitors contain less energy than larger capacitors, and therefore, a larger change in the voltage across them will occur during the time that the output is turning on. Because of this, the size of the capacitance tends to limit the maximum amount of current sinking throughout the output and therefore, the amount of ground bounce. Larger capacitors, however, do not experience such a large change in voltage as the outputs turn on. For very large capacitances, there is almost no change in the voltage across them, and they behave much like a power supply. Under these conditions, the maximum amount of current that will sink through the outputs is limited by the outputs themselves. Increasing the capacitance does not increase the current and therefore, does not increase the ground bounce.
Figure 10 shows the effect of varying only the capacitive loading on the active output. Here, the filtering effect of the load can be observed clearly. As the load capacitance is increased, it filters the signal and reduces the amplitude of the ground bounce.
Because they generate more AC current during switching, capacitive loads tend to generate more ground bounce noise than resistive loads. Fortunately, most actual PCB traces will be long enough so that they react like an impedance and not lumped capacitive loads.

the board clock source. The logic diagram for this line is represented in Figure 17. An address bus driver was chosen because of the length of the line and the number of loads on it. Here, the ground bounce amplitude was 1.1 V . We can see that this signal line is connected to devices of many different technologies and functions, including LS and memory products. After the host processor was replaced, the system exhibited no performance degradation due to the device replacement.
It can be seen from the previous figures that the type and location of the output loads have a major effect on ground bounce. It is also obvious that standard test loads generate the most ground bounce. Even reducing the capacitive load, or moving it away from the output still generates more noise than a typical application.

## OUTPUT PIN LOCATION

The location of the output pin with respect to the device ground also affects the magnitude of ground bounce. Tests have shown that outputs located closer to the ground lead generally have $30 \%$ to $50 \%$ less noise than pins further away. The effects of pin location are portrayed in Figures 18 and 19. Figure 18 shows the ground bounce on the worstcase pin, which is the one farthest away from ground. Figure 19 shows the ground bounce on the best-case pin, the one closest to ground. By choosing outputs close to ground, the amount of ground bounce may be reduced by nearly half.

## POWER SUPPLY VOLTAGE EFFECTS

The value of $V_{D D}$ also affects the amplitude of the ground bounce. By reducing the $V_{D D}$ level, not only is the output voltage swing reduced, but also the amount of current that the output can deliver. Both of these tend to reduce ground bounce.
Figure 20 tabulates the results of varying both $\mathrm{V}_{\mathrm{DD}}$ and load capacitance. All of these numbers were taken on a standard test fixture. Note that while the amplitude of the ground bounce changes linearly with voltage, it is not merely the ratio of the voltage levels. Reducing the $V_{D D}$ by $40 \%$ (from 5.0 V to 3.0 V ) reduces the ground bounce by almost $60 \%$. Since the amplitude of the ground bounce decreases faster than the input threshold, there is a net gain in the noise margin.
Figure 21 represents the same results taken on the ground bounce demo board. The ground bounce was measured with $\mathrm{V}_{\mathrm{DD}}=3.0 \mathrm{~V}$. The amount of ground bounce was reduced to 800 mV , even with standard test loads. It should be pointed out that 'ACXXX devices can be used in a 5 V TTL system with a $\mathrm{V}_{\mathrm{DD}}$ of $3.3 \mathrm{~V} \pm 0.3 \mathrm{~V}$. Under these conditions, the outputs will still drive an incident wave on a $75 \Omega$ transmission line for the commercial temperature range and $100 \Omega$ for the military temperature range. With $V_{D D}$ equal to 3.3 V , FACT 'ACXXX devices have TTL-compatible inputs and outputs.

TL/F/10232-23
FIGURE 20. Quiet Output Noise vs Power Supply

## TEST FIXTURES VS REAL SYSTEMS

Because ground bounce is so dependent upon the load the device is driving, it has proven to be one characteristic of CMOS devices that does not correlate well between results taken on standard test fixtures and results seen in actual systems. This occurs for several reasons. First, the AC loading presented by standard text fixtures is not the same as the AC loading generated by a system load, and second, the standard test load creates a LCR tank circuit that tends to oscillate during edge transitions.
For these reasons, ground bounce data taken on test fixtures is useful for comparative analysis, but is not valid for predicting actual system performance.

## AC LOADING EFFECTS

Standard text fixtures use 50 pF of capacitance and $500 \Omega$ of resistance to simulate a "typical load," as shown in Figure 22. It is possible to achieve good correlation between propagation delay data taken using these test loads and data taken in real systems. Unfortunately, this is not true for ground bounce. While this lumped load testing was adequate for older, slower technologies, it is not as useful for the newer, faster logic families. As edge rates go up, more and more circuit traces react like transmission lines, not lumped loads. For devices having edge rates of approximately 3 ns , traces longer than 6-8 inches will exhibit transmission line characteristics and cannot be treated as lumped loads.

FIGURE 21. Quiet Output Noise-VDD $=3.0 \mathrm{~V}$

TL/F/10232-25
FIGURE 22. Standard Test Load

Figures $23 a$ and $23 b$ are models of a capacitive load and a transmission line load, respectively. In Figure 23a, we replace the capacitor with a power supply. This simulates our circuit at the time when the output transistor has just turned on, and the full capacitor voltage is applied across the device. In Figure 23b, the transmission line is replaced with a resistor to the power supply. This simulates the AC characteristics of the transmission line.
Comparing the two figures, we notice that while the capacitive load applies the full voltage directly to the device output, the transmission line acts like an additional resistance between the voltage and the device output. Clearly, one would expect more current to flow with the capacitive load than with the resistive load. Since the output transistor turns on just as fast in both cases, the capacitive load will create a greater $\mathrm{dl} / \mathrm{dt}$, causing more voltage to be induced across the ground lead inductance. Because of this, standard test fixtures tend to generate two to three times more ground bounce noise than system printed circuit traces. This is still true for traces that may have more capacitance than the 50 pF lumped load used in standard test fixtures.

FIGURE 23a. Test Fixture

## LCR TANK EFFECTS

Referring back to Figure 1a, notice the LCR tank circuit that is formed by the load capacitance, parasitic inductances and output resistance. Imagine each edge transition as a single impulse into this tank circuit; it would be expected to oscillate. Theoretically, the frequency of the oscillation should be somewhere in the range around 1.3 GHz . Typically, oscillations are observed in the frequency range of 100 MHz to 200 MHz . There are several reasons for this discrepancy.
The output transistor does not behave like a pure resistance. The transistor tends to limit the available current to less than 160 mA to 180 mA . Additionally, there are other parasitic elements associated with the output transistor affecting the frequency of oscillation.
Because most circuit traces react like impedances and not capacitances, this type of oscillation is not seen when FACT devices drive typical circuit traces.
Figures 22 and 23 highlight the differences between ground bounce in a standard test fixture and in a comparable PCB trace. The results of the test fixture (Figure 24) are much greater than the results of the PCB circuit trace (Figure 25). This is due to the greater current requirements caused by the lumped capacitive load versus a distributed load.

FIGURE 23b. System Models

## FIGURE 24. Quiet Output-Standard Test Fixture

The difference in oscillation between a standard test fixture and a typical circuit trace is also shown. Even though the circuit trace has more capacitance than the test fixture, it is not lumped at the output, but distributed along the circuit trace.
For these reasons, ground bounce data taken on test fixtures is useful for comparative analysis, but is not valid for predicting actual system performance.

## MANIFESTATIONS OF GROUND BOUNCE

The problems associated with ground bounce occur because the induced voltage across the ground leads creates a voltage differential between the external system ground and the internal device ground. This voltage affects both inputs and outputs, although differently.
The difference between the external and internal grounds must be taken into account to arrive at the actual input threshold. Noise on either the internal ground or $V_{D D}$ will cause the input thresholds to change. CMOS input thresholds are generally $50 \%$ of the voltage across the input structure, i.e., if $\mathrm{V}_{\mathrm{DD}}$ is 5.0 V , then the input threshold will be 2.5 V . Now, if the ground bounces positively 1.0 V , the net voltage across the input structure will be reduced to 4.0 V . This will cause the input threshold to shift up to 3.0 V ( 1.0 V of ground rise $+50 \% \times 4.0 \mathrm{~V}$ ). Conversely, if the ground bounces negatively 1.0 V , the input threshold will drop down to $2.0 \mathrm{~V}(-1.0 \mathrm{~V}+50 \% \times 6.0 \mathrm{~V})$. If during this time a quiet input is held between 2.0 V and 3.0 V , the input structure will detect a change of state.
Regarding the outputs, the effect is somewhat different. Any output that is LOW is essentially tied to the internal ground through a very low impedance: approximately $10-12 \Omega$. Therefore, any output will tend to follow the internal ground as it shifts with respect to the external ground. This causes any LOW outputs to also shift with respect to external ground.

TL/F/10232-31
7 Outputs Switching $V_{D D}=5 \mathrm{~V}$; Heavy Load
Worst-Case Output Pin; Ten Loads on Quiet Output
FIGURE 25. Quiet Output Noise-System Bus
There are four predominant manifestations of ground bounce which we will discuss: 1) altered device states, where a device assumes a state that is not intended or expected, 2) undershoot noise on active signals, 3) propagation delay degradation, and 4) noise on quiet (static) outputs.

## ALTERED DEVICE STATES

Of these four symptoms, the most critical is altered device states. Altered device states occur when a device assumes a state that is not intended or expected by the system designer. The results can range from glitches on the outputs to permanently-altered data in registers or counters. Ground bounce can cause these types of problems when it is great enough to cause an external signal to be sensed incorrectly in the device.

FIGURE 26. Example of Ground Bounce

In CMOS devices, the input thresholds are generally a percentage of the voltage across the input structure. Generally, the input levels are $50 \%$ for CMOS level inputs and $30 \%$ for TTL-level inputs. As the internal ground and power levels shift with respect to the external power and ground planes, the input thresholds will also shift. If the shift is great enough to cause the input threshold to go above an external HIGH signal (so that the input signal looks LOW) or below an external LOW signal (so that the input looks HIGH), the input will detect a change of state. Depending upon the input type, several results can occur.
If the input is a synchronous one, such as the data input into a D-type flip-flop, then the device should not be affected. If the input is combinatorial, or the data input to a transparent latch, the output may glitch.
The effects may be more damaging if the input is asynchronous, such as a clock, preset, set, load, or clear. With these inputs, data in the internal counters or registers may be corrupted. Most likely, this type of data corruption can usually cause a system to fail, or generate invalid results.
FACT devices are characterized during initial device evaluation to ensure that the device will not exhibit this problem.

## PROPAGATION DELAY DEGRADATION

Propagation delay degradation is a phenomenon familiar to most system designers. As more than one output on a single device is switched, the propagation delay, as measured to the input threshold level, will become longer. To understand how this happens with CMOS devices, consider Figure 27 ; any voltage developed across the inductor L1 will reduce the voltage across the output impedance R1. This, in turn reduces the current through R1. Since the rate of voltage change across the load capacitance is directly related to the current available, a decrease in current reduces the rate at which the output voltage changes, i.e., the edge rate slows down. This, in turn, slows down the propagation delay because more time is required for the output to go from one rail to the input threshold. As additional outputs are switching simultaneously, the voltage across the inductor increases, and the current available to charge or discharge the load capacitance will be less.

TL/F/10232-32
FIGURE 27. Output Model

Figure 28 illustrates the effects of multiple output switching on the propagation delay of a FACT device. Here we see that as more outputs switch, the edge rate of those outputs drops off.
While it is not possible to test this type of parameter in an ATE environment, National understands its importance to system designers. Since this type of measurement can be made in a bench environment, FACT devices are evaluated during initial device characterization to insure that this propagation delay degradation is less than 250 ps per additional output switched.

## UNDERSHOOT ON ACTIVE SIGNALS

Undershoot noise on active signals is generally created by impedance mismatches in transmission lines. Yet, it can also be created by ground bounce. Figure 29 shows the voltage that is generated across the inductor during the edge transition. While at the beginning of the transition the ground bounce is positive, at the end it is negative. This is due to the currents turning off as the output reaches the end of its voltage swing.

TL/F/10232-33
FIGURE 28. Propagation Delay vs Number of Outputs Switching
Unfortunately, the negative ground bounce occurs when the output is finishing its transition. The output will follow the internal ground as a quiet output would. This results in the output undershooting and then returning to ground.

TL/F/10232-34

## FIGURE 29. Quiet Output Noise Concurrent

 with Active EdgeUndershoot amplitudes are generally slightly less than the associated ground bounce. This undershoot noise will generally not be a problem because most standard logic families have input structures, such as clamp diodes, that tend to damp it out. However, some specialized devices, exemplified by dynamic RAMs, may be sensitive to undershoots greater than -2.0 V .

## QUIET OUTPUT NOISE

Quiet, or static, output noise is usually the symptom of ground bounce that is first noticed by system designers. As pointed out earlier, quiet output noise occurs because LOW outputs tend to follow internal ground. If there is a shift between the external and internal grounds, it will appear as noise on a quiet output. The effects of this noise can range from noise on the output signals to system failure. If the noise is great enough to cross the input threshold on the next device on the line, this next device may react.
The reaction, of course, will depend upon the type of input. If the input is synchronous, the ground bounce noise will not propagate through the input into the device. If the input is combinatorial or asynchronous, output glitches or corrupted counters or registers may result. In order to predict the effects of this noise, it is necessary to consider some typical applications.
As shown earlier, ground bounce amplitude is dependent upon the number of outputs switching. Therefore, devices which have fewer outputs will have less noise. Because of this, our discussions will be limited to octal devices and their applications.

FIGURE 30. Application Segments

## SYNCHRONOUS DATA/ADDRESS BUSSES

One of the largest application segments for octal devices is driving/receiving data and address busses. In these bus applications, the receiver is usually synchronous and latches in the data on a clock edge. In Figure 29, notice that the quiet output noise exists only when the active outputs are switching. In addition, both quiet and active outputs achieve this stable and valid state within the propagation delay time specified in the FACT Data Book.
During the time that the data or address is latched in (when the data is expected to remain stable and valid) the quiet outputs are as stable and valid as the active outputs. Therefore, valid data will always be clocked in, and in these systems, no additional work is required to achieve maximum system performance and reliability.

## ASYNCHRONOUS CONTROL LINES

A much smaller application segment is driving asynchronous signals. Octal devices, like the ' 240 series, offer eight buffers in a 20-pin package. This feature can be useful to the system designer trying to reduce board size and part count. It is in these applications that problems are most likely to occur. However, there are several factors that work in the designer's favor.
It is important to look at the type of input that is being driven. CMOS-level inputs have much greater low noise margins than TTL-level inputs. Standard CMOS inputs have input thresholds set to $50 \%$ of $V_{D D}$. This means that if $V_{D D}$ equals 5.0 V , there is 2.5 V of low noise margin. Test results show that the ground bounce will never be this great in a system. In addition, as noted above, the actual ground bounce noise expected in a real system is less than the AC noise margins of most TTL families.
Finally, it is very important to note that the duration of the ground bounce noise spike is short (tyically 2-3 ns @ 0.8 V ). Typically, AC noise margins increase with decreasing pulse width. This is more pronounced in slower technologies. Figure 31 shows the typical low level input noise thresholds of FAST, Schottky, and Low Power Schottky. For pulse width typically seen with ground bounce noise, the AC noise margins of FAST and Schottky approach 2.0 V and 1.5 V respectively. Even LS devices, which have the lowest input thresholds, have AC noise margins that exceed 2.0 V for pulse

## Low Level Noise Immunity

TL/F/10232-35

TL/F/10232-36
FIGURE 31. AC Noise Thresholds
widths as great as 8 ns . For ground bounce type noise pulses, with widths of $2-3 \mathrm{~ns}$, the LS AC thresholds are well above 2.0 V .
There are also several design techniques under the system designer's control which can be used to minimize ground bounce noise, thereby eliminating ground bounce-induced problems.
The first factor that should be considered, in many cases, is that the need for a buffer can be eliminated. This is due to the fact that all FACT logic devices feature the same 24 mA output stages. A quick example will help to clarify this. For the example, a divide-by-2 clock generator drives a clock onto a large processor board. Figure 32a shows the circuit built with ALS devices while Figure 32b shows the same circuit built with FACT devices. The difference is obvious: the ALS circuit required a buffer to drive the clock line because the 'ALS74 does not have enough output drive to drive the line. On the other hand the 'AC74 has the same drive capability as the 'AC240, so adding the buffer is redundant. In addition, the output of the 'AC74 is double buffered to isolate the internal logic from noise on the outputs. Removing an additional propagation delay gains performance advantages besides board space and part count savings. If it is not possible to remove the buffer, the designer can still insure minimum noise on the output. This can be accomplished with several methods, some of which are discussed here.
Board-level timing analysis may show that not all of the outputs can switch at the same time. Under these conditions, the worst-case ground bounce will be reduced (Figure 6). As

TL/F/10232-37
(a)

TL/F/10232-38
(b)

## FIGURE 32. Example Circuits

mentioned earlier, outputs closer to the ground pin may have up to $50 \%$ less noise than outputs further away. Therefore, asynchronous lines should be driven from outputs closer to the device ground pin whenever possible.
Some other methods, which may be more difficult to implement, include reducing the power supply voltage or using two power supply voltages. Running the system $V_{D D}$ lower (closer to 4.5 V ) will reduce the ground bounce noise levels of the CMOS devices while not affecting the input thresholds of the TTL devices. In addition, as we stated earlier, the $V_{D D}$ value for the CMOS devices can be lowered to 3.3 V . This reduces the ground bounce by $60 \%$ while maintaining TTL-compatible inputs and outputs. For a small number of CMOS devices, a standard zener diode regulated circuit may be used. For larger numbers of devices, a second (3.3V) power plane may be added.

Take a moment to summarize the material covered thus far. While at first glance, the problems associated with quiet output noise may seem to be the most precarious to system designers, there are many issues that affect them. First, a large percentage of the octal applications are synchronous busses. In these applications, quiet output noise will not be a problem.
It is the smaller segment of asynchronous applications that are most suspect. Fortunately, only octal devices generate enough ground bounce noise to be of serious concern. Secondly, if the inputs are CMOS, the input noise margins are greater than any ground bounce. If the inputs are TTL, the ground bounce will generally be less than the TTL AC input noise margins. Additionally, designers have several techniques available to reduce the ground bounce. These include: a) use logic devices that provide buffer-type drive capability, thereby eliminating the need for these octal buffers (all FACT devices have the same 24 mA outputs); b) do not have all of the outputs on an octal device switch simultaneously; c) select outputs closer to the ground pin for driv-
ing asynchronous inputs, and d) reduce the $V_{D D}$ level. Any or all of these may be used to eliminate the possibility of system failures due to quiet output noise in the small number of octal applications where these problems might occur. Most applications require no special precautions.
The major points of concern regarding ground bounce:
Ground bounce occurs because of the parasitic inductances found in all conductors.
Ground bounce causes shifts in input thresholds and noise on outputs.
There are many factors which affect the amplitude of the ground bounce:

- Number of outputs switching simultaneously: More outputs mean more ground bounce.
- Type of output load: Lumped capacitive loads generate 2 to 3 times more gorund bounce than system traces. Increasing the capacitive load increases ground bounce to approximately $60-70 \mathrm{pF}$. Beyond 70 pF , ground bounce drops off due to the filtering effect of the load. Moving the load away from the output reduces the ground bounce.
- Location of the output pin: Outputs closer to the ground pin exhibit less ground bounce than those further away.
- Voltage: Lowering $V_{D D}$ reduces the ground bounce.
- Test fixtures: Standard test fixtures generate 30 to $50 \%$ more ground bounce than a typical system since they use capacitive loads which increase the AC load and form LCR tank circuits that oscillate.
Ground bounce produces several symptoms:
- Altered device states. FACT logic does not exhibit this symptom.
- Propagation delay degradation. FACT devices are characterized not to degrade more than 250 ps per additional output switching.
- Undershoot on active outputs. The worst-case undershoot will be approximately equal to the worst-case quiet output noise.
- Quiet output noise: FACT's worst case quiet output noise has been measured to be around $500-1100 \mathrm{mV}$ in real system applications.

## DESIGN RULES

From this, we can develop a simple set of rules that will protect any system from problems associated with ground bounce. This set of design rules listed below is recommended to ensure reliable system operation by providing the optimum power supply connection to the devices. Most designers will recognize these guidelines. These guidelines are the same ones as those they have been using for years for the advanced bipolar logic families.
Use multi-layer boards with $\mathrm{V}_{\mathrm{DD}}$ and ground planes, with the device power pins soldered directly to the planes, to insure the lowest power line impedances possible.
Use decoupling capacitors for every device, usually $0.10 \mu \mathrm{~F}$ should be adequate. These capacitors should be located as close to the ground pin as possible.
Avoid using sockets or wirewrap boards.
Avoid connecting capacitors directly to the outputs.
In addition, observing either one of the following rules is sufficient to avoid running into any of the problems associated with ground bounce.
Use caution when driving asynchronous TTL-level inputs from CMOS octal outputs.
Use caution when running control lines (set, reset, load, clock, chip select) which are glitch sensitive through the same device that drive data or address lines.
While it is desirable to avoid the above conditions, there are simple precautions available which can minimize ground bounce noise. These are:
Locate these outputs as close to the ground pin as possible. Use the lowest $V_{D D}$ as possible or split the power supply.
Use board design practices which reduce any additive noise sources, such as crosstalk, reflections, etc.
Ground bounce is an unwanted noise source that is found in most logic families available today. Due to increased edge rates and voltage swings, ground bounce can be more of a problem with new Advanced CMOS logic families. National, with the vast experience in high performance logic design gained from its leadership position with the FAST family, defined FACT logic so that high performance problems, as exemplified by ground bounce, were minimized while not sacrificing performance. By following the simple design guidelines outlined, designers can use FACT logic to maximize system performance while ensuring their systems are free from the problems associated with ground bounce.

## Dynamic Threshold for Advanced CMOS Logic

## INTRODUCTION

Most users of digital logic are quite familiar with the threshold specifications found on family logic data sheets. Designers using products with TTL level input thresholds will see numbers like $\mathrm{V}_{I H}=2.0 \mathrm{~V}$ and $\mathrm{V}_{I L}=0.8 \mathrm{~V}$. These threshold guarantees are static, a part's response to these levels during switching transients can be undesirable. Through the course of this paper the reader should gain an understanding for the difference between a static threshold and a dynamic threshold. This paper will also discuss how various products respond dynamically, how dynamic thresholds are tested, and specified. Lastly, this paper will look at how FACT Quiet Series ${ }^{\text {TM }}$ has addressed and specified dynamic threshold characteristics.

## WHAT IS A DYNAMIC THRESHOLD?

If National Semiconductor were able to package its I.C.'s in "ideal" packages, then dynamic and static thresholds would be one and the same. However, our package, like that of all our competitors, is not "ideal" and has a finite amount of inductance associated with each signal lead. As will be shown later, it is the inductance in the power leads which are the primary cause for the non-ideality.
To understand the phenomena of dynamic thresholds the properties of ground bounce must first be exarnined. Figure 1 is a representation for a 74 XX 00 product which includes package inductance. Figure $2 a$ shows an output pulldown making an HL/ZL transition. In discharging the load capacitor a current $\mathrm{I}_{\mathrm{C}}$ equaling $\mathrm{C}^{*} \mathrm{dv} / \mathrm{dt}$ flows into the chip, this current is approximated versus time in Figure $2 b$. The changing current, $\mathrm{I}_{\mathrm{C}}$, generates a voltage across the ground inductor represented in Figure $2 c$ through the equation $\mathrm{L}^{*} \mathrm{di} / \mathrm{dt}$. It is the voltage across the ground inductor, commonly known as ground bounce, which is the cause for static and dynamic thresholds to differ.

TL/F/10643-1
FIGURE 1. A Typical " 00 " 2-Input Quad NAND Gate

FIGURE 2
The threshold of an IC is referenced to its internal ground. Therefore, voltages induced on the ground inductor are reflected directly as a change in threshold with respect to external ground. Figure 3 shows the effects of ground bounce on an input threshold. If when the threshold is moving it crosses the input voltage levels, a problem area exists. However, having the threshold cross the input level does not necessarily induce a product failure. The threshold must cross the input level for a period of time for a false switch to occur. (Figure 4 shows the voltage time relationship). Note that in the high speed technologies two things have come together, faster delays and output edge rates, generally meaning larger di/dt's, and an ability to react to narrower pulses.

FIGURE 3

TL/F/10643-5
FIGURE 4
In the example discussed above, ground bounce was outlined as the cause for the threshold change. For bipolar TTL technologies, this is the only noise source of concern since the threshold is created by a $V_{B E}$ stack referenced to ground. As $V_{D D}$ changes in a bipolar circuit, the threshold will change logarithmically as the currents in the transistors change, i.e., a 1 V change in $V_{D D}$ creates approximately a 34 mV shift in threshold. CMOS thresholds are set up as a percentage of $V_{D D}$ and track linearly with $V_{D D}$ changes. Therefore, a noise spike on $V_{D D}$ from an LH/ZH transition generates dynamic threshold characteristics which must be considered along with those of the HL/ZL edges. In this example let internal ground bounce to a 1 V peak; the bipolar threshold will peak to approximately 2.5 V while the CMOS circuit will peak to $\left(\left(V_{\text {th }} / V_{D D} *\left(V_{D D}-V_{\text {bounce }}\right)+\right.\right.$ $1.0 \mathrm{~V})=\left(\left(0.3^{*}(4.0)+1.0\right)=2.2 \mathrm{~V}\right.$. Consider a negative bounce of 1 V on the internal $\mathrm{V}_{D D}$ bus, the threshold delta for the bipolar product will be negligible, but the CMOS chip's threshold will change as follows: $\left(\left(\mathrm{V}_{\mathrm{th}} / \mathrm{V}_{\mathrm{DD}}{ }^{*}\left(\mathrm{~V}_{\mathrm{DD}}-\right.\right.\right.$ $\left.\left.\mathrm{V}_{\text {bounce }}\right)\right)=\left(0.3^{*}(4)\right)=1.2 \mathrm{~V}$.

## HOW ARE DYNAMIC THRESHOLDS SPECIFIED?

A circuits dynamic threshold characteristics are quantified with the specifications $V_{I H D}$ and $V_{I L D}$, where the " $D$ " appendage stands for "dynamic". The definitions are as below,

- $\mathrm{V}_{\text {IHD }}$ - The minimum HIGH input level such that normal switching/functional characteristics are observed during output transients.
- $\mathrm{V}_{\text {ILD }}$ - The maximum LOW input level such that normal switching/functional characteristics are observed during output transients.

## HOW ARE DYNAMIC THRESHOLDS CHARACTERIZED?

The characterization of dynamic thresholds requires some planning for each product. The test will vary depending upon which edge will generate the supply noise; i.e., is the edge an LH or a ZL? Is the test for a data or control pin? This section discusses the planning process for testing an ACQ244, ACQ374, and an FCT534. From this discussion the reader should be able to test other products and understand the FACT Quiet Series dynamic noise specifications.
Test Fixturing/Setup: Dynamic threshold tests are sensitive to the test configuration. The same considerations used to measure AC propagation delays should be exercised. $\mathrm{Na}-$ tional Semiconductor uses the same fixturing for both AC propagation delay and noise testing. The inputs for this test are driven with a word generator running at 1 MHz which has been deskewed such that no more than 150 ps exists between channels. FACT Quiet Series specifies $\mathrm{V}_{\text {IHD }} / \mathrm{V}_{\text {ILD }}$ at $25^{\circ} \mathrm{C}$ with $V_{D D}$ at 5.0 V . For CMOS, true worst case exists where ground bounce is maximized, at cold temp high $V_{D D}$. Bipolar circuits are not as straightforward; the threshold has a temperature coefficient tracking its $\mathrm{V}_{\mathrm{BE}}$ stack which can change nearly a volt from $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$. The temperature and $V_{D D}$ that create worst case bounce may not induce worst case $\mathrm{V}_{\mathrm{IHD}} / \mathrm{V}_{\text {ILD }}$.

Each product subject to $\mathrm{V}_{\text {IHD }} / V_{\text {ILD }}$ testing will have multiple test possibilities. Through the case studies below, the reader should gain an understanding for some of the test tradeoffs.

## Case 1: Product $=$ ACTQ244 test data pins with $\mathrm{LH} / \mathrm{HL}$ transitions.

The algorithm for this test is as follows. Maximize the number of outputs switching, $N$, in this case $8 . N-1$ of the inputs will be transitioning to and from nonthreshold levels, $0 \mathrm{~V}-3 \mathrm{~V}$. The last input will transition from 3 V to $\mathrm{V}_{\text {ILD }}$ or from OV to $\mathrm{V}_{\mathrm{IHD}}$. Figure 5 shows the four combinations of tests. It should be noted that values of $\mathrm{V}_{\text {ILD }}$ and $\mathrm{V}_{\text {IHD }}$ that induce failure will vary as a function of the test pin. This is due mostly to voltage drops on the internal power bussing. As a result, pins farthest from the ground pin, and sometimes the $V_{C C}$ pin, are likely to be worst case pins.
Case 2: Product $=$ ACTQ244 test data pins with $\mathrm{ZL} / \mathrm{ZH}$ transitions.
This test will ramp the enable pin from $3 \mathrm{~V}-0 \mathrm{~V}$ while holding the input under test at threshold, i.e., have all outputs transitioning $Z L$, with $N-1$ inputs at $O V$ and the input under test at $\mathrm{V}_{\text {ILD }}$. The other tests are as follows, $\mathrm{N}-1$ transitioning ZL pin under test (PUT) at $\mathrm{V}_{\text {IHD }}$, all outs going ZH PUT at $\mathrm{V}_{\mathrm{IHD}}$, and $\mathrm{N}-1$ a ZH switch and PUT at $\mathrm{V}_{\mathrm{ILD}}$.
Case 3: Product $=$ ACTQ244 test $O E$ pin with HL/LH transitions.
$V_{\text {ILD }}$ is the parameter to check here. Data inputs should be switching $0 \mathrm{~V}-3 \mathrm{~V}$ while the OE pin is being stepped up from OV to VILD. While testing the OE pin with an LH output tran-

sition, the standard $50 \mathrm{pF}, 500 \Omega$ load should be used. When testing with an HL on the output, the TRI-STATE ${ }^{\oplus}$ ZL/LZ $500 \Omega$ to $\mathrm{V}_{\mathrm{CC}}{ }^{*} 2$ should be used. Without the pullup resistor, failure cannot be detected. The LZ and HZ edges create supply noise by switching off currents being sourced or sunk by the device. With standard AC loading, their transients are much less than those of the other edges. Therefore, $\mathrm{V}_{\mathrm{IHD}}$ for the chip is guaranteed by the data pins.
The test cases discussed in cases 1-3 are all possible test methods, note there are other possible combinations. In practice National has found that tests done in conjunction with HL transitions are worst case, i.e., case 1, and will guarantee $V_{I L D}$ and $V_{I H D}$ for the chip.
Case 4: Product $=$ ACTQ374
This class of function, the non-inverting register, will have very good data and clock pin dynamic threshold characteristics. For instance, take the worst case bounce where all output are transitioning HL. To accomplish this, all inputs are LOW on the active edge of clock. If a $\mathrm{V}_{\mathrm{IHD}}$ test of the clock were performed, the positive ground bounce at some level of $\mathrm{V}_{I H D}$ will stimulate one, if not multiple, false clocks to occur. A failure is not detected because the false clock or clocks merely regenerated an existing low output. The positive ground bounce had the effect of making the logic low data look lower. Always associated with positive bounce is negative bounce, which on an HL transition occurs later. If this negative bounce is able to switch the internal data gate, setup and hold times have been violated and again failure is not detected. Reference Figure 6 for a representation of this scenario.

(a)

TL./F/10643-11
(b)

FIGURE 6

The most rigorous test for the non-inverting flop will be to have clock held at $\mathrm{V}_{\mathrm{IHD}}$, data at a hard HIGH, and all outputs are transitioning ZL .
Case 5: Product = FCTQ534
The inverting products, as this one is, inherently have poorer $\mathrm{V}_{\text {IHD }} / \mathrm{V}_{\text {ILD }}$ characteristics than the non-inverting. While testing a 240 is straightforward, the 534 testing and results require further consideration. While the output is transitioning, both data and clock are HIGH. If data is held at a hard HIGH and clock lowered, false clocks occur, but a failure is not detected. The reverse is also true, as data is lowered, the data gate changes, but no clocks occur. However, as both data and clock HIGH levels are lowered simultaneously a window of $\mathrm{V}_{I H D}$ failure will be observed.
Figure 7 plots this "window of failure". This plot will be examined by sweeping from right to left. It can be seen that for
clock $\mathrm{V}_{\text {IHD }}$ levels down to approximately 2.6 V , proper data continues to clock out for data levels down to 1.5 V , the static threshold value. For all $\mathrm{V}_{\mathrm{IHD}}$ voltages of the clock below 2.6 V , false clocking exists. If data is raised high enough, no internal data changes occur and therefore no product test failures. A data is lowered, internal data pulses down (Figure 8). The initial internal pulses may not cause device failure either because the voltage has not dropped to a valid logic level or because setup and hold times to the master latch have not been satisified, but eventually failures are observed. It is interesting to note that were the FCT534 to have a more positive hold time, its hold time is slightly negative, the data voltage inducing failure would be much lower.

FIGURE 8

The implication of the data in Figure 7 is that if the high voltage levels droop down to approximately 2.9 V on data and 2.6 V on clock simultaneously, a system failure is possible. How can these conditions exist at the same time? The temperature of Figure 7 is $0^{\circ} \mathrm{C}$, if the inputs are driven by TTL drivers at a $\mathrm{V}_{\mathrm{DD}}=4.5 \mathrm{~V}, 2.6 \mathrm{~V} \mathrm{~V}_{\mathrm{OH}}$ 's are possible. However, the $V_{D D}$ of the plot is 5.25 , assuming the driver TTL chips are on the $V_{D D}$ bus, the HIGH levels will be greater than 2.6 V . There is another variable to be considered before stating that no problem exists: what termination scheme is being used? If both data and clock signals come from transmission lines using either parallel or thevenin termination, HIGH voltage levels below 2.6 V are possible. If either or both of the signals are unterminated, series terminated, or AC terminated then functionality is assured. In summary, a problem may exist if this parts data and clock pins are driven by parallel or thevenin terminated transmission lines while the $V_{D D}$ bus is at 5.25 V and the junction temperature is $0^{\circ} \mathrm{C}$.

## HOW DO DYNAMIC THRESHOLD PROBLEMS MANIFEST THEMSELVES?

There are three main modes of failure during dynamic threshold testing. Firstly, the part can malfunction through a state change. Also possible are oscillations, glitches, AC delay changes, and slew rate degradation. One octal register tested recently was seen to exhibit metastable type characteristics. Failure criteria are as follows.

- On a LOW output the LOW level will not rise above a TTL threshold LOW, 0.8 V , after the transition of the output.
- On a HIGH output the HIGH level will not drop below a CMOS threshold HIGH, 3.5V @ $\mathrm{V}_{\mathrm{DD}}=5.0 \mathrm{~V}$, after the transition of the output.
- If the natural ringing, other than initial switching rail bounce, of the output violates the previous two criteria then the ringing amplitude will be noted. Failure is then defined as a 100 mV movement in the output toward the threshold from the peak ringing amplitude, (Figure 9).
- Gross failures will include functional state changes, oscillations, AC delay changes, and slew rates effects.

## HOW DO DYNAMIC THRESHOLD PROBLEMS AFFECT DIFFERENT FUNCTIONS?

All the products discussed thus far pass the FACT Quiet Series dynamic threshold limits of $\mathrm{V}_{\mathrm{IHD}}=2.2 \mathrm{~V}$ and $\mathrm{V}_{\text {ILD }}=$ 0.8 V , which are specified as being tested singularly. The case of the FCTQ534 represents one where much effort was required to observe the failure mode. There are classes of product that will display clock $\mathrm{V}_{\text {IHD }}$ failures readily. These would be products which toggle the outputs independent of data. The most common functions in the list would be counters and shift registers. If the 74XXX299 clock pin were tested, the initial clock edge would shift data inducing ground bounce. If the clock $V_{I H D}$ is low enough, it will be that observed false clocks will continue until all outputs are in the same logic state as the serial data pin.

FIGURE 9

## WHAT DOES FACT QUIET SERIES DO TO ADDRESS DYNAMIC THRESHOLDS?

The Quiet Series product utilizes two technical innovations to accomplish its performance. First, by using a split ground bus configuration, input and output grounds are given a degree of isolation. Schematically this is shown in Figures 10a and $b$. The ground bus for inputs stages and outputs sections are separated on chip and only connected by the common inductance near the shoulder of the package and a mutual inductance between the leadframe fingers. Note, the $V_{D D}$ input and output $V_{D D}$ busses are electrically shorted on chip by the substrate resistance. The leadframe inductance forms a voltage divider such that the input only sees a percentage of the output ground noise. Secondly, a proprietary GTOTM technology, shown in Figure 10c, is used to shape the output edge. This then yields an output voltage waveform shown in Figure 10d. The soft turn on of the output attenuates the $\mathrm{dv} / \mathrm{dt}$, and therefore the $\mathrm{di} / \mathrm{dt}$ presented to the ground inductance, yielding a reduction in the ground noise.

## HOW DOES NATIONAL COMPARE WITH OTHER VENDORS?

The characteristics of National Semiconductor's FACT Quiet Series ensure superior dynamic threshold performance in conventional corner pinned packaging. The split power rail technology used to isolate inputs and outputs addresses a noise issue which goes unresolved in multiple power pin ACL logic families, and most single pin families. The same split rail technology is used in the FACT FCT and FCTA logic lines. Referencing the FCT534 already discussed, Figure 11 shows one of the dramatic differences created by the Quiet Series technology.

## SUMMARY

With the new advanced CMOS technologies, the specifications and characteristics for dynamic thresholds need to be considered along with the other variables that impact the choice of a device type or family. This applications note has discussed the theories of test philosophy, failure criteria, and the root causes of dynamic thresholds. This information should provide the systems designer the tools to analyze any impact to design performance.

## Design Innovations Address Advanced CMOS Logic Noise Considerations

## UNDERSTANDING THE FUNDAMENTALS OF NOISE

Today's electronic system designers are becoming increasingly more familiar with the issues involved in migrating to high-speed logic. One key issue is total system noise.
Noise in an electronic system can be described according to its source. The first category is system-generated noise, i.e., noise generated from the printed board up, such as power distribution and decoupling noise, crosstalk noise, electromagnetic interference (EMI), and transmission line reflections. System noise is a function of signal characteristics such as edge rate, voltage swing, and frequency. This type of noise can be minimized by strictly adhering to proper printed circuit board design practice commonplace in the design of ECL-based systems. The system designer can do more to control this type of noise than device-generated noise.
Device-generated noise is the second category, i.e., noise that is generated at the integrated circuit level such as simultaneous switching noise, or ground bounce, device undershoot, and dynamic input threshold shift. System designers may use techniques that minimize the level of devicegenerated noise. Device-generated noise is more effectively minimized by the IC designer and manufacturer. In some asynchronous applications, such as the distribution of timing signals, use of inherently lower-noise ICs can be critical.

## CONTROLLING SYSTEM-GENERATED NOISE IS CRITICAL

The power distribution network is a key source of system noise. High-performance logic switches large amounts of current in a short amount of time and almost always requires multiple-plane printed circuit boards with separate power and ground planes instead of traces. Due to their high impedance, power and ground traces may generate too large of a power supply droop for low noise systems.
In addition, the logic's switching-current demand also requires bypass capacitors for each device, located as close to power or ground pin as possible. Usually a $0.1 \mu \mathrm{~F}$ ceramic chip capacitor provides adequate decoupling. Including power supply decoupling at every step of the system design is critical for a high-performance, low-noise system. Power supply noise is easily coupled and radiated throughout the system.
Crosstalk is another system noise. If not addressed during system design, it can create problems in high-performance systems. Crosstalk refers to the noise created when a signal on an "active" trace is coupled onto an adjacent parallel "quiet" signal trace.
Forward crosstalk manifests itself as a negative voltage spike on the adjacent quiet trace and results from mutual inductance effects. Its amplitude and duration are generally much less than reverse crosstalk. Reverse crosstalk is noise on the quiet trace resulting from a combination of ca-pacitively-coupled and mutually-induced energy from the active signal trace. Its amplitude and duration are determined
by the active signal's edge rate and the length of adjacent parallel traces. The faster the edge or the closer the adjacent traces, the higher the crosstalk amplitude. The longer the adjacent traces run, the longer the duration of the reverse crosstalk. Reverse crosstalk travels in the direction opposite to the active signal's propagation and lasts for twice the one-way delay time of the signal trace.
Crosstalk control methods include minimizing the coupled trace length and maximizing the distance between the two adjacent traces. If board area does not allow large spaces between lines, the insertion of a ground trace between the two adjacent traces also minimizes crosstalk.
Proper termination of all adjacent traces is important in minimizing crosstalk. Reflections are also propagating signals and will create crosstalk. Terminating adjacent transmission lines will eliminate the reflected signal.
Electromagnetic Interference (EMI) is another type of system noise. EMI is the radiation of energy outside the system. Whenever an electric charge is accelerated, electromagnetic waves result. The efficiency of this process is mainly determined by the geometry of the charge paths. The most significant charge paths in a system are the printed circuit board signal traces, power supplies, and I/O cables. The largest and most plentiful charge paths, they are also leading sources of EMI.
The EMI bandwidth is a function of the signal frequency, amplitude, edge rate, duty cycle, edge discontinuity, and ringing. These characteristics of high-performance logic, especially advanced CMOS logic, can cause signal traces and I/O cables to radiate more noise than ever before. The higher frequencies generated as a result of these characteristics will radiate more efficiently from signal lines because of their shorter wavelengths.
Addressing the characteristics of a signal that may create EMI is critical to reducing EMI, or achieving electromagnetic compatibility (EMC). Reliable solutions to EMC include proper shielding and grounding of all cables as well as proper termination of all signal traces. Adhering to other system design guidelines for power supply decoupling and crosstalk can also minimize EMI. Some of the output edge control techniques discussed later will also minimize EMI by directly effecting several key signal characteristics.
The last major form system noise is reflections on the transmission line and the resultant ringing. Ringing observed on signal traces has two sources: one is system-generated; the other, device-generated. The two are often confused. It is important to note that improperly terminated transmission lines will create ringing caused by reflections, i.e., systemgenerated noise.
Reflections are caused by mismatches in impedance from driver to transmission line or from transmission line to receiver/termination. The magnitude of these reflections is related to the length of the transmission line and the impedance along the line. Transmission line impedances and driver/receiver I/O impedances seldom match. Most often
these impedances are orders of magnitude different. With the edge rates of today's advanced CMOS logic, transmission lines of approximately 20 centimeters ( 8 inches) or longer will most probably need some type of termination.
Choosing the right termination scheme is important. When designing with low-power advanced CMOS, do not select a termination that will dissipate several tens of milliamperes. Popular bipolar terminations such as a DC parallel termination (resistor to ground) or a Thevenin (voltage divider) termination (resistors to both rails) draw large amounts of DC current. Effective termination schemes that preserve low CMOS power consumption are a series resistor (for a single driver/receiver pair) or an AC parallel termination (resistor in series with a capacitor to ground) for distributed multiple loads.
Device-generated ringing is due to the parasitic LCR tank circuits in the IC and its load. The stimulus for this type of ringing is an overshoot or undershoot in the output signal. This ringing is minimized by slowing the output edge rate with higher loads or by improvements in IC circuitry.

## WHAT IS DEVICE-GENERATED NOISE?

Device-generated noise includes dynamic threshold shift, ground bounce, and output undershoot.
The first type of device-generated noise is dynamic threshold shift. System designers are very familiar with DC input threshold requirements, namely $\mathrm{V}_{\mathrm{IH}}$ (Input Voltage HIGH) and $\mathrm{V}_{\mathrm{IL}}$ (Input Voltage LOW). For TTL-based logic, these levels are typically 2.0 V and 0.8 V , respectively. For CMOSbased logic, these levels are typically $70 \%$ and $30 \%$ of $V_{D D}$, respectively and are measured and guaranteed in a static (DC) mode only. Switching any part of the device-under-test is an invalid condition. In a real-life situation the IC is dynamic and so are the input thresholds.

FIGURE 1. Dynamic Threshold
Dynamic input threshold shifts arise when one or several of the inputs are toggled, generating noise on the device's onchip power rails. The input threshold voltage is proportional to the power supply voltage. Any fluctuation of these rails, such as ground bounce and/or undershoot, will create fluctuations of the input threshold. Figure 1 illustrates a nega-
tive excursion on the internal ground of an IC. The input threshold tracks this excursion and crosses through the static LOW input level. This creates an unwanted change of state on the output when the threshold falls below the input level. In this case, an undershoot caused by bounce on the chip ground causes a normally valid input level to create an invalid output state.
Dynamic threshold shifts may create problems on synchronizing inputs should the device's output noise be great enough to cause the device's threshold voltage to shift across the input voltage level. On TTL-compatible inputs, dynamic threshold shifts could substantially reduce an already low noise margin.
In addition to causing erroneous changes in state, the output may begin to go into a high-frequency oscillation as input voltage levels approach the dynamic threshold. Regardless of whether the input in question is a synchronizing input, this high frequency oscillation will increase chip heating. Should this situation continue, device reliability could be effected.

TL/F/10655-2
FIGURE 2. Ground Bounce Model
The second type of device-generated noise is ground bounce or simultaneous switching noise. Ground bounce or $V_{\text {OLP }}$ (Voltage Output LOW, Peak) and undershoot or VolV (Voltage Output LOW, Valley) are names given to noise levels associated with the output of a logic device. While these two issues are not new to logic, they are of greater concern with advanced logic families. Since advanced CMOS outputs switch rail to rail at high speed and into heavy loads, performance and design concerns have risen in this area.
Similary, $\mathrm{V}_{\mathrm{DD}}$ droop and overshoot are also device-generated noise issues. However, since both affect the logic HIGH level and since using CMOS outputs to drive TTL inputs provides much higher noise margin than the logic LOW level, this discussion focuses on low-level noise margin issues.

As the model in Figure 2 illustrates, ground bounce is the voltage induced on the device ground inductance by current as it quickly discharges from a capacitive load, sinking into the output's N -channel transistor. The greater the amount and rate of discharge that is created by multiple simultaneously switching outputs, the greater the ground bounce level. Essentially there are more current sources sinking current into the same ground inductor
Device undershoot or VoLV (Voltage Output LOW, Valley) is simply a function of the LCR tank circuit at the output. As edge rates increase, undershoot and subsequent ringing increase. Undershoot also decreases as the capacitive load
on the output increase and/or as the inductance of the output decreases. Therefore, advanced CMOS logic devices driving one or two other advanced CMOS logic devices will have more undershoot than an advanced CMOS device driving a heavily loaded bus. For this reason, in most systems undershoot levels are much less than those observed in test fixture environments. Also, improper bus termination may appear to worsen undershoot. In fact it is the energy of the reflected wave that increases the undershoot and not the device itself. Most undershoot levels in excess of 2.0 V are the result of some mismatched impedance along the transmission line and can be eliminated with proper termination.

FIGURE 3. Example of Ground Bounce

FIGURE 4. Location of Bounce Pulse

## WHERE CAN DEVICE-GENERATED

## NOISE AFFECT SYSTEM PERFORMANCE?

An integrated circuit ground inductor's di/dt is determined by the number of outputs switching and the capacitive load on each output. In a system, transmission line effects will reduce the effective capacitive load the output may actually drive. In a test fixture, the load is made up of low-dissipation factor chip capacitors soldered directly to the output pins. In a system, a finite physical distance separates the various capacitive loads from each other as well as the driver's output. The net effect of capacitance distributed along the transmission line is to lower the effective impedance of the transmission line. As a result, ground bounce in a system is typically $50 \%$ less than test fixture measurements. Test fixture measurements of ground bounce should only be used for comparative analysis and characterization.
The magnitude of system ground bounce and the segment of applications where that bounce may present problems is very small. Ground bounce occurs concurrently with the transition of the active outputs of the device. Ground bounce on quiet output(s) driving synchronous signalssuch as data and address lines-are not of concern since these signals will not be synchronized or sampled until long after ground bounce has settled out. See Figure 4.
However, while asynchronous signals, such as resets, presets, latch enables, and clock lines, typically number far fewer than synchronous signals in a system they may be more susceptible to ground bounce.
Since substantial ground bounce voltage levels are only achieved with six or more outputs switching simultaneously in the same package, device with eight or more bits, i.e., octals, are the primary focus of ground bounce.
Also, noise signals, such as ground bounce, driven into CMOS-level inputs generally have no effect due to the higher amount of energy needed to switch CMOS inputs. Typical voltage levels needed to switch full CMOS inputs are 3.0 V for approximately 2.0 ns ; ground bounce levels in a system
or a test fixture do not reach this level. However, ground bounce on asynchronous signals into TTL-input levels may cause system errors. Typically TTL inputs need only 1.7 V of noise of 2.0 ns to switch (e.g. FAST® and ALS).
For these reasons, the small segment of applications where ground bounce noise may compound with system noise levels and possibly affect system performance is where advanced CMOS octals drive asynchronous signals into TTLlevel inputs. See Figure 5. Since the mechanisms are similar, shifts in dynamic threshold are also a possible concern in this small segment.
Undershoot, either on quiescent low or high-to-low switching outputs, can create noise problems in some systems by generating excess ringing on the signal line. As stated earlier, ringing also adds to EMI and crosstalk noise. Additionally, most devices driven by logic devices have clamp diodes on their inputs that will limit the input voltage excursions. However, as devices such as DRAMs, DACs, and PLDs have no protection and are sensitive to negative voltage excursions on the input, system faults or damage to these devices, caused by latch-up, may result. The use of series resistors can safeguard against such faults.
The system designer may further minimize ground bounce and undershoot effects by choosing surface mount technology (SMT). SMT package inductance on the order of 2 nH to 4 nH can reduce ground bounce and undershoot by as much as $25 \%$, without the board area penalty incurred by larger non-standard pinout. Also, if the design allows, placing asynchronous signal lines on pins closest to the ground pin will minimize the noise on these lines-as much as $20 \%$ less noise than pins furthest from ground.
If device-generated noise is still a critical issue in the system design, National Semiconductor Corporation has implemented several design improvements that greatly minimize device-generated noise. The result is an extension to the FACTTM line-FACT Quiet Series or FACT QS.

## DESIGN INNOVATIONS RESOLVE DEVICE NOISE ISSUES

FACT Quiet Series implements patented technological breakthroughs in device-generated noise suppression as well as several major performance improvements. Design improvements include a split ground bus and leadframe, a graduated output N -channel turn-on circuit, and an output undershoot correction circuit.
The first design improvement, a split ground bus and leadframe, addresses dynamic threshold shift. Since the cause of threshold shift is noise on the IC ground bus created by simultaneous output switching, separating the output and input ground buses virtually eliminates dynamic threshold shift.
FACT QS has separate on-chip ground buses for the input transistors and for the remainder of the internal gates, including the output transistors. FACT QS goes one step further to isolate output noise from the inputs by implementing a split leadframe for the ground pin. Figure 8 illustrates the change in the ground bus structure. Note that the split leadframe joins just prior to exiting the cavity. Standard pinout, package quality, and reliability are maintained using this technique.

Resulting from output noise, dynamic threshold shifts are worst-case under conditions of multiple simultaneously switching outputs. Values of dynamic thresholds on advanced CMOS without the split ground bus and leadframe range from 0.3 V to 0.7 V .
The result of the split ground bus and leadframe is a dynamic threshold equivalent to the static threshold. For FACT ACTQ logic, typical dynamic threshold is 1.4 V for a logic low. In this way, output switching noise becomes inconsequent to the input using split ground bussing. National Semiconductor's FACT QS, FACT FCT and FACT FCTA logic lines all incorporate split ground bus and leadframe improvements.
A second design improvement, a graduated output N -channel turn-on circuit (GTOTM), greatly reduces ground bounce. As Figure 2 illustrated, ground bounce is a function of the output waveshape, $\mathrm{d}^{2} \mathrm{v} / \mathrm{dt}^{2}$. Reducing package and chip inductance does have some effect in reducing ground bounce, but the reduction in ground bounce is not linear with inductance reduction. Package inductances may change by an order of magnitude, yet ground bounce is reduced only by as much as $25 \%$.

Second order effects, such as increases in di/dt as output reactance is decreased, cause ground bounce reductions to flatten as inductance is reduced. The cost of reducing inductance on dual-in-line packages is an increased number of power and ground pins, increased package size, and a non-standard pinout. Package pinout changes have negligible effect on surface mount devices where inductance is low to begin with.
The greater reduction in ground bounce is found by rounding the transition point on the high-to-low edge, or waveshaping. Figure 9 illustrates the effect of output waveshaping on ground bounce. This waveshaping is actually achieved by combining several design techniques. The two most notable are the slow decay of the load capacitance charge through a soft turn-on circuit prior to the actual transition, and the delaying of the actual turn-on of the large N -channel output transistor.
Since ground bounce levels are more substantial on the high-to-low transition, the low-to-high transition remains unchanged. In addition, design considerations were taken to ensure the integrity of the high-to-low edge rate, and thereby maintain device AC performance.
Ground bounce on advanced CMOS logic without output waveshaping is on the order of 2.0 V to $3.0 \mathrm{~V} \mathrm{~V}_{\mathrm{OLP}}$ in a test fixture environment. In the same environment, FACT QS, with the GTO circuitry, provides $V_{\text {OLP }}$ performance in the range of 1.0 V to 1.3 V . In a system, $30 \%$ to $50 \%$ lower Volps should result.

The third design improvement, undershoot corrector circuitry (USCTM), reduces output undershoot, both on the switching and quiescent (at ground) outputs. Undershoot is also a matter of di/dt. As output edge rates speed up and voltage swings increase, undershoot increases. Undershoot also increases as the number of simultaneously switching outputs increases. The result, $V_{\text {OLV }}$, can be seen on both the switching edges as well as outputs quiescent at ground.
The undershoot correction circuit works by limiting negative di/dt excursions. The first part of this two-stage circuit senses a high-to-low edge. At a predetermined point on that edge, the undershoot corrector is turned on. The corrector simply activates a P-channel transistor which sources current into the output. This softens the di/dt that occurs when the load is depleted of charge. An internal RC timer controls the duration and decay of the correction.
Should the RC timer time out before undershoot is fully resolved, a differential amplifier, sensing that the output voltage is still below the input ground, keeps the current source turned on. This two-stage design is more reliable because of the time required for the current injector to turn on after the output goes negative.
Because USC operation is affected by package inductance, plastic DIP packages react differently than ceramic DIP packages. Similarly, surface mount devices have a different correction level. As ground bounce and undershoot decrease with decreasing inductance, the need for undershoot correction also decreases with decreasing inductance.

FIGURE 12. ACMOS Dynamic Threshold Comparison

## OUTPUT CONTROL CIRCUITRY RESULTS IN LOWER NOISE

Figures 10 and 11 compare three major ACMOS product lines. These ACMOS manufacturers have different levels of noise suppression. All measurements were taken using an industry-accepted fixture and methodology.
FACT QS is manufactured on a smaller geometry CMOS process than standard FACT products. Because of the use of this technology, FACT QS AC speeds are faster than standard FACT. Propagation delays as well as set-up and hold times are also specified identically to or faster than standard FACT.

## DESIGN IMPROVEMENTS GO BEYOND NOISE

In addition to improvements which reduce device-generated noise, FACT QS also incorporates design improvements for greatly enhanced performance and reliability. These parameters include specification of output pin-to-pin propagation delay skew, higher electrostatic discharge (ESD) immunity, and higher latchup immunity, than standard FACT products.
Pin-to-pin skew becomes an issue as high-performance logic is designed into clock distribution and other timing-sensitive applications. Since, part-to-part skews are not effected by variations in $V_{D D}$ or temperature, the only variable that could effect part-to-part skew is processing variations from one device to another. Part-to-part skews may be interpreted by subtracting the $25^{\circ} \mathrm{C}, 5.0 \mathrm{~V}-\mathrm{V}_{\mathrm{DD}}$ propagation delay minimum specification from the maximum specification on most advanced CMOS logic data sheets.
Guaranteed ACMOS logic pin-to-pin skew specifications are unique to National Semiconductor's FACT QS product line. For clock distribution applications where all outputs tran-
sition to the same state simultaneously, output skew is typically less than 500 ps , with worst case being 1.0 ns . For bus applications where outputs can transition to either state simultaneously, typical skew is less than 800 ps , with worst case being 1.0 ns .
Another performance improvement is higher ESD immunity. Process improvements for FACT QS have improved ESD immunity to $8,000 \mathrm{~V}$ or better. ESD is specified at $6,000 \mathrm{~V}$ typical, with worst case being at $4,000 \mathrm{~V}$ minimum. MIL Class 3 ( $4,000 \mathrm{~V}$ or more) is guaranteed.
A third performance improvement in National's FACT QS is a higher latch-up immunity specification. As with standard FACT, the implementation of epitaxial silicon in the FACT process essentially eliminated latch-up possibility. The currents needed to latch-up devices manufactured on the FACT processes are typically in excess of 1A. FACT QS latchup immunity is tested to 300 mA on the inputs and up to 1A on the outputs. Latchup immunity is specified at 300 mA minimum at $+125^{\circ} \mathrm{C}$.

## General Description

The 'AC/'ACTOO contains four 2-input NAND gates.

## Features

■ Outputs source/sink 24 mA

- 'ACT00 has TTL-compatible inputs
m Standard Military Drawing (SMD)
— 'AC00: 5962-87549
- 'ACT00: 5962-87699

Ordering Code: See Section 8

## Logic Symbol

IEEE/IEC

TL/F/9911-1

Connection Diagrams

TL/F/9911-2

| Pin Names | Description |
| :--- | :--- |
| $\mathrm{A}_{n}, \mathrm{~B}_{\mathrm{n}}$ | Inputs |
| $\overline{\mathrm{O}}_{\mathrm{n}}$ | Outputs |

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
-0.5 V to +7.0 V
DC Input Diode Current ( $I_{\mathrm{IK}}$ )
$\begin{array}{ll}V_{1}=-0.5 \mathrm{~V} & -20 \mathrm{~mA} \\ V_{1}=V_{C C}+0.5 \mathrm{~V} & +20 \mathrm{~mA}\end{array}$
DC Input Voltage $\left(V_{1}\right)$

$$
-0.5 \mathrm{~V} \text { to } \mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
$$

DC Output Diode Current (lok)

$$
V_{O}=-0.5 \mathrm{~V}
$$

$$
-20 \mathrm{~mA}
$$

$$
V_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
$$

$$
+20 \mathrm{~mA}
$$

DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source
or Sink Current (lo)
DC VCC or Ground Current per Output Pin (ICC or IGND)
$\pm 50 \mathrm{~mA}$
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
CDIP
$175^{\circ} \mathrm{C}$
PDIP
$140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage (VCC)
'AC
2.0 V to 6.0 V
'ACT
Input Voltage $\left(V_{1}\right)$ 4.5 V to 5.5 V OV to $\mathrm{V}_{\mathrm{CC}}$ OV to $\mathrm{V}_{\mathrm{CC}}$
Output Voltage (VO)
Operating Temperature $\left(T_{A}\right)$
74AC/ACT
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'AC Devices
$V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{C C}$
$\mathrm{V}_{\mathrm{CC}} @ 3.3 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'ACT Devices
V IN from 0.8 V to 2.0 V
$\mathrm{V}_{\mathrm{CC}}$ @ $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$

## DC Characteristics for 'AC Family Devices

## 54AC/74AC02®54ACT/74ACT02 <br> Quad 2-Input NOR Gate

## General Description

The 'AC02/'ACT02 contains four, 2-input NOR gates.
The information on the ACT02 is Preliminary Information Only.

## Features

■ Outputs source/sink 24 mA

- 'ACT02 has TTL-compatible inputs
© Standard Military Drawing (SMD) — AC02: 5962-87612

Ordering Code: See Section 8

Logic Symbol

Connection Diagrams

TL/F/9912-3

TL/F/9912-2

| Pin Names | Description |
| :--- | :--- |
| $A_{n}, B_{n}$ | Inputs |
| $\bar{O}_{n}$ | Outputs |

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (VCC)
DC Input Diode Current ( $l_{\mathrm{IK}}$ )
$V_{1}=-0.5 \mathrm{~V}$
$V_{1}=V_{C C}+0.5 \mathrm{~V}$

DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
DC Output Diode Current (IOK)

$$
\begin{aligned}
& V_{O}=-0.5 \mathrm{~V} \\
& V_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
\end{aligned}
$$

-0.5 V to +7.0 V

C Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current (IO)
DC $V_{C C}$ or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG) Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
$175^{\circ} \mathrm{C}$
PDIP

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating

 ConditionsSupply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )
'AC

Input Voltage ( $\mathrm{V}_{\mathrm{I}}$ )
Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
Operating Temperature $\left(T_{A}\right)$

## 74AC/ACT

$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
54AC/ACT
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Minimum Input Edge Rate $(\Delta \mathrm{V} / \Delta \mathrm{t})$
'AC Devices
$\mathrm{V}_{\mathrm{IN}}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\mathrm{CC}}$
$V_{C C}$ @ $3.3 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate $(\Delta \mathrm{V} / \Delta \mathrm{t})$ 'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$V_{C C} @ 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
2.0 V to 6.0 V 4.5 V to 5.5 V OV to $\mathrm{V}_{\mathrm{CC}}$ OV to $\mathrm{V}_{\mathrm{CC}}$

## 54AC/74AC04 • 54ACT/74ACT04 Hex Inverter

## General Description

The 'AC/'ACT04 contains six inverters.
The information for the ACT04 is preliminary information only.

## Features

■ Outputs source/sink 24 mA

- 'ACT04 has TTL-compatible inputs
- Standard Military Drawing (SMD)
— 'AC04: 5962-87609

Ordering Code: See Section 8

## 54AC/74AC10 • 54ACT/74ACT10 Triple 3-Input NAND Gate

## General Description

The 'AC/'ACT10 contains three, 3-input NAND gates. The information for the ACT10 is Preliminary Information only.

## Features

[ Outputs source/sink 24 mA

- ${ }^{\text {Standard Military Drawing (SMD) }}$
- 'AC10: 5962-87610
Ordering Code: See Section 8
Logic Symbol

Pin Assignment for DIP Flatpak and

TL/F/9915-3

TL/F/9915-2

| Pin Names | Description |
| :--- | :--- |
| $A_{n}, B_{n}, C_{n}$ | Inputs |
| $\bar{O}_{n}$ | Outputs |

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required,
please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
-0.5 V to +7.0 V
DC Input Diode Current (IIK)
$V_{1}=-0.5 \mathrm{~V}$
$V_{1}=V_{C C}+0.5 V$
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
DC Input Voltage ( $V_{l}$ )
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Diode Current (lok)
$V_{\mathrm{O}}=-0.5 \mathrm{~V}$
$\mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current (o)
DC V $V_{C C}$ or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG) Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
-0.5 V to to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$\pm 50 \mathrm{~mA}$
$\pm 50 \mathrm{~mA}$
$-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$
$175^{\circ} \mathrm{C}$
$140^{\circ} \mathrm{C}$

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating

 ConditionsSupply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )

| 'AC | 2.0 V to 6.0 V |
| :--- | :--- |
| 'ACT | 4.5 V to 5.5 V |

Input Voltage ( $\mathrm{V}_{1}$ )
Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
Operating Temperature ( $\mathrm{T}_{\mathrm{A}}$ ) 74AC/ACT 54AC/ACT
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'AC Devices
$\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\mathrm{CC}}$
$V_{C C}$ @ $3.3 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate $(\Delta V / \Delta t)$
'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$V_{C C}$ @ 4.5V,5.5V $125 \mathrm{mV} / \mathrm{ns}$

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating Conditions

Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) $\begin{array}{ll}\text { 'AC } & 2.0 \mathrm{~V} \text { to } 6.0 \mathrm{~V} \\ \text { 'ACT } & 4.5 \mathrm{~V} \text { to } 5.5 \mathrm{~V}\end{array}$
Input Voltage ( $\mathrm{V}_{1}$ )

## 54AC/74AC14 Hex Inverter with Schmitt Trigger Input

## General Description

The 'AC14 contains six inverter gates each with a Schmitt trigger input. The 'AC14 contains six logic inverters which accept standard CMOS input signals and provide standard CMOS output levels. They are capable of transforming slowly changing input signals into sharply defined, jitter-free output signals. In addition, they have a greater noise margin than conventional inverters.

The 'AC14 has hysteresis between the positive-going and negative-going input thresholds (typically 1.0 V ) which is determined internally by transistor ratios and is essentially insensitive to temperature and supply voltage variations.

## Features

- Outputs source/sink 24 mA
- Standard Military Drawing (SMD)
- 'AC14: 5962-87624

## 54AC/74AC74 • 54ACT/74ACT74 Dual D-Type Positive Edge-Triggered Flip-Flop

## General Description

The 'AC/'ACT74 is a dual D-type flip-flop with Asynchronous Clear and Set inputs and complementary ( $Q, \bar{Q}$ ) outputs. Information at the input is transferred to the outputs on the positive edge of the clock pulse. Clock triggering occurs at a voltage level of the clock pulse and is not directly related to the transition time of the positive-going pulse. After the Clock Pulse input threshold voltage has been passed, the Data input is locked out and information present will not be transferred to the outputs until the next rising edge of the Clock Pulse input.

Asynchronous Inputs: LOW input to $\bar{S}_{D}$ (Set) sets $Q$ to HIGH level LOW input to $\bar{C}_{D}$ (Clear) sets $Q$ to LOW level Clear and Set are independent of clock Simultaneous LOW on $\overline{\mathrm{C}}_{\mathrm{D}}$ and $\overline{\mathrm{S}}_{\mathrm{D}}$ makes both Q and $\overline{\mathrm{Q}}$ HIGH

## Features

■ Output source/sink 24 mA

- 'ACT74 has TTL-compatible inputs
- Standard Military Drawing (SMD)
- 'AC74: 5962-88520
- 'ACT74: 5962-87525

Ordering Code: See Section 8

## Logic Diagram

TL/F/9920-6
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Rating (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )
-0.5 V to +7.0 V
DC Input Diode Current ( $I_{I K}$ )
$\begin{array}{ll}V_{1}=-0.5 \mathrm{~V} & -20 \mathrm{~mA} \\ V_{1}=V_{C C}+0.5 \mathrm{~V} & +20 \mathrm{~mA}\end{array}$
DC Input Voltage $\left(V_{1}\right)$

$$
-0.5 \mathrm{~V} \text { to } \mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
$$

DC Output Diode Current (IOK)

$$
V_{O}=-0.5 \mathrm{~V}
$$

$$
-20 \mathrm{~mA}
$$

$$
V_{O}=V_{C C}+0.5 \mathrm{~V}
$$

$$
+20 \mathrm{~mA}
$$

DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current (lo)
DC V ${ }_{\mathrm{CC}}$ or Ground Current per Output Pin (ICC or IGND)
$\pm 50 \mathrm{~mA}$
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
CDIP
$175^{\circ} \mathrm{C}$
PDIP
$140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating Conditions

Supply Voltage (VCC) 'AC
Input Voltage ( $\mathrm{V}_{1}$ ) 4.5 V to 5.5 V OV to $\mathrm{V}_{\mathrm{CC}}$ OV to $\mathrm{V}_{\mathrm{CC}}$
Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
74AC/ACT
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'AC Devices
$\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\mathrm{CC}}$
$V_{\text {CC }}$ @ 3.3V, 4.5V, 5.5 V
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$V_{C C}$ @ 4.5V, 5.5 V
$125 \mathrm{mV} / \mathrm{ns}$

## 54AC/74AC86 <br> Quad 2-Input Exclusive-OR Gate

## General Description

The 'AC86 contains four, 2-input exclusive-OR gates.

## Features

- Outputs source/sink 24 mA

■ Standard Military Drawing (SMD)
— 'AC86: 5962-89550

Ordering Code: See Section 8
Logic Symbol

Pin Assignment for DIP, Flatpak and SOIC

Pin Assignment for LCC
$B_{1}$ NC $A_{1} N C O_{0}$ [8] [7] [5]

TL/F/9909-1

| Pin Names | Description |
| :--- | :--- |
| $A_{0}-A_{3}$ | Inputs |
| $B_{0}-B_{3}$ | Inputs |
| $O_{0}-O_{3}$ | Outputs |

## Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

## Supply Voltage (VCC)

-0.5 V to +7.0 V
DC Input Diode Current ( $I_{\mathrm{I}}$ )

$$
\begin{aligned}
& V_{1}=0.5 \mathrm{~V} \\
& V_{1}=V_{C C}+0.5 V
\end{aligned}
$$

DC Input Voltage ( $\mathrm{V}_{\mathrm{I}}$ )
DC Output Diode Current (IOK)

$$
\begin{aligned}
& V_{O}=-0.5 \mathrm{~V} \\
& V_{O}=V_{C C}+0.5 \mathrm{~V}
\end{aligned}
$$

DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current (o)

$$
\begin{aligned}
& -20 \mathrm{~mA} \\
& +20 \mathrm{~mA}
\end{aligned}
$$

-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$

$$
\begin{aligned}
& -20 \mathrm{~mA} \\
& +20 \mathrm{~mA}
\end{aligned}
$$

-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$\pm 50 \mathrm{~mA}$
DC V CC or Ground Current
Per Output Pin (ICC or $\mathrm{I}_{\mathrm{GND}}$ )
$\pm 50 \mathrm{~mA}$
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
PDIP $140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )

| 'AC | 2.0 V to 6.0 V |
| :--- | ---: |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage $\left(\mathrm{V}_{1}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage $\left(\mathrm{V}_{\mathrm{O}}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Operating Temperature $\left(\mathrm{T}_{\mathrm{A}}\right)$ |  |
| 74AC/ACT | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| 54AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'AC Devices $V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{\text {CC }}$ $\mathrm{V}_{\mathrm{CC}} @ 3.3 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'ACT Devices $\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V $V_{C C} @ 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$

## 54AC/74AC109 • 54ACT/74ACT109 Dual JK Positive Edge-Triggered Flip-Flop

## General Description

The 'AC/'ACT109 consists of two high-speed completely independent transition clocked $\sqrt{\mathrm{K}}$ flip-flops. The clocking operation is independent of rise and fall times of the clock waveform. The $\sqrt{\mathrm{K}}$ design allows operation as a D flip-flop (refer to 'AC/'ACT74 data sheet) by connecting the $J$ and $\bar{K}$ inputs together.
Asynchronous Inputs:
LOW input to $\bar{S}_{D}$ (Set) sets $Q$ to HIGH level
LOW input to $\overline{\mathrm{C}}_{\mathrm{D}}$ (Clear) sets $Q$ to LOW level

Clear and Set are independent of clock Simultaneous LOW on $\overline{\mathrm{C}}_{D}$ and $\overline{\mathrm{S}}_{D}$ makes both $Q$ and $\overline{\mathrm{Q}}$ HIGH

## Features

- Outputs source/sink 24 mA
- 'ACT109 has TTL-compatible inputs
- Standard Military Drawing (SMD)
— 'AC109: 5962-89551
- 'ACT109: 5962-88534

Logic Diagram (one half shown)

Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Rating (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributurs for availability and specifications.
Supply Voltage (VCC)
-0.5 V to +7.0 V
DC Input Diode Current (IK)
$V_{1}=-0.5 \mathrm{~V}$
$V_{I}=V_{C C}+0.5 \mathrm{~V}$
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
DC Input Voltage ( $\mathrm{V}_{\mathrm{I}}$ )
DC Output Diode Current (IOK)
$\mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V}$
$\mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$

DC Output Voltage (Vo)
DC Output Source or Sink Current (lo)
DC $V_{C C}$ or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG) Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
$175^{\circ} \mathrm{C}$ PDIP $140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )
'AC
2.0 V to 6.0 V
'ACT
4.5 V to 5.5 V

Input Voltage ( $\mathrm{V}_{1}$ )
Output Voltage (VO)
OV to $\mathrm{V}_{\mathrm{CC}}$
OV to $\mathrm{V}_{\mathrm{CC}}$
Operating Temperature $\left(T_{A}\right)$

| 74AC/ACT | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| :--- | ---: |
| 54AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'AC Devices
$V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{C C}$
$V_{C C}$ @ 3.3V, $4.5 \mathrm{~V}, 5.5 \mathrm{~V} \quad 125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$\mathrm{V}_{\mathrm{CC}} @ 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$

## 54AC/74AC125•54ACT/74ACT125 Quad Buffer with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'AC/'ACT125 contains four independent non-inverting buffers with TRI-STATE outputs.

## Features

(1. Outputs source/sink 24 mA

- 'ACT125 has TTL-compatible outputs

Ordering Code: See Section 8

## Logic Symbol

IEEE/IEC

## Connection Diagrams

Pin Assignment for DIP, SOIC and Flatpak

TL/F/10692-2

Pin Assignment for LCC and PCC

TL/F/10692-3

[^13]Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
-0.5 V to +7.0 V
DC Input Diode Current ( $\mathrm{I}_{\mathrm{K}}$ )

$$
\begin{aligned}
& V_{1}=-0.5 V \\
& V_{1}=V_{C C}+0.5 V
\end{aligned}
$$

$$
-20 \mathrm{~mA}
$$

$$
+20 \mathrm{~mA}
$$

DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Diode Current (lok)
$\mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V}$
$\mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Voltage (V)
DC Output Source or Sink Current (lo)
DC V CC or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG) Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
PDIP
$175^{\circ} \mathrm{C}$
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$\pm 50 \mathrm{~mA}$
$\pm 50 \mathrm{~mA}$
$-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ $140^{\circ} \mathrm{C}$

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating Conditions

Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )
'AC
Input Voltage ( $\mathrm{V}_{1}$ )
Output Voltage (V)
Operating Temperature $\left(T_{A}\right)$

| $74 \mathrm{AC} / \mathrm{ACT}$ | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| :--- | ---: |
| 54AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'AC Devices $\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\mathrm{CC}}$ $\mathrm{V}_{\text {CC }}$ @ $3.3 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$

125 mV/ns
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$V_{C C}$ @ 4.5V,5.5V $125 \mathrm{mV} / \mathrm{ns}$

## 54AC/74AC138 • 54ACT/74ACT138 1-of-8 Decoder/Demultiplexer

## General Description

The 'AC/'ACT138 is a high-speed 1 -of-8 decoder/demultiplexer. This device is ideally suited for high-speed bipolar memory chip select address decoding. The multiple input enables allow parallel expansion to a 1-of-24 decoder using just three 'AC/'ACT138 devices or a 1-of-32 decoder using four 'AC/'ACT138 devices and one inverter.

## Features

- Demultiplexing capability
- Multiple input enable for easy expansion
- Active LOW mutually exclusive outputs
- Outputs source/sink 24 mA
- 'ACT138 has TTL-compatible inputs
- Standard Military Drawing (SMD)
— 'AC138: 5962-87622
- 'ACT138: 5962-87554

Ordering Code: See Section 8

## Logic Symbol

| Pin Names | Description |
| :--- | :--- |
| $A_{0}-A_{2}$ | Address Inputs |
| $\bar{E}_{1}-\bar{E}_{2}$ | Enable Inputs |
| $E_{3}$ | Enable Input |
| $\overline{\mathrm{O}}_{0}-\bar{O}_{7}$ | Outputs |

## Connection Diagrams

## Functional Description

The 'AC/'ACT138 high-speed 1-of-8 decoder/demultiplexer accepts three binary weighted inputs ( $A_{0}, A_{1}, A_{2}$ ) and, when enabled, provides eight mutually exclusive active-LOW outputs $\left(\overline{\mathrm{O}}_{0}-\overline{\mathrm{O}}_{7}\right)$. The 'AC/'ACT138 features three Enable inputs, two active-LOW ( $\bar{E}_{1}, \bar{E}_{2}$ ) and one active-HIGH ( $\mathrm{E}_{3}$ ). All outputs will be HIGH unless $\bar{E}_{1}$ and $\bar{E}_{2}$ are LOW and $E_{3}$ is HIGH. This multiple enable function allows easy parallel expansion of the device to a 1-of-32 (5 lines to 32 lines)
decoder with just four 'AC/'ACT138 devices and one inverter (see Figure 1). The 'AC/'ACT138 can be used as an 8output demultiplexer by using one of the active LOW Enable inputs as the data input and the other Enable inputs as strobes. The Enable inputs which are not used must be permanently tied to their appropriate active-HIGH or activeLOW state.

$$

$$
+20 \mathrm{~mA}
$$

DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ ) or Sink Current (lo)
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
-0.5 V to to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$\pm 50 \mathrm{~mA}$
DC VCC or Ground Current per Output Pin (ICC or IGND)
$\pm 50 \mathrm{~mA}$
Storage Temperature ( $\mathrm{T}_{\mathrm{STG}}$ )
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
$175^{\circ} \mathrm{C}$
$140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating Conditions

Supply Voltage (VCC)

Input Voltage ( $\mathrm{V}_{1}$ )
Output Voltage (VO)
Operating Temperature $\left(T_{A}\right)$

## 74AC/ACT

$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Minimum Input Edge Rate $(\Delta \mathrm{V} / \Delta \mathrm{t})$
'AC Devices

## 54AC/74AC139•54ACT/74ACT139 Dual 1-of-4 Decoder/Demultiplexer

## General Description

The 'AC/'ACT139 is a high-speed, dual 1-of-4 decoder/demultiplexer. The device has two independent decoders, each accepting two inputs and providing four mutually-exclusive active-LOW outputs. Each decoder has an activeLOW Enable input which can be used as a data input for a 4-output demultiplexer. Each half of the 'AC/'ACT139 can be used as a function generator providing all four minterms of two variables.

## Features

- Multifunction capability
- Two completely independent 1-of-4 decoders
active LOW mutually exclusive outputs
■ Outputs source/sink 24 mA
- 'ACT139 has TTL-compatible inputs
- Standard Military Drawing (SMD)
-'AC139: 5962-87623
-'ACT139: 5962-87553

Ordering Code: See Section 8

## Functional Description

The 'AC/'ACT139 is a high-speed dual 1-of-4 decoder/demultiplexer. The device has two independent decoders, each of which accepts two binary weighted inputs $\left(A_{0}-A_{1}\right)$ and provides four mutually exclusive active-LOW outputs ( $\overline{\mathrm{O}}_{0}-\overline{\mathrm{O}}_{3}$ ). Each decoder has an active-LOW enable ( $\overline{\mathrm{E}}$ ). When $\bar{E}$ is HIGH all outputs are forced HIGH. The enable can be used as the data input for a 4-output demultiplexer application. Each half of the 'AC/'ACT139 generates all four minterms of two variables. These four minterms are useful in some applications, replacing multiple gate functions as shown in Figure a, and thereby reducing the number of packages required in a logic network.

DC Output Diode Current (IOK)

$$
\begin{aligned}
& V_{\mathrm{O}}=-0.5 \mathrm{~V} \\
& \mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
\end{aligned}
$$

DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current (lo)
-0.5 V to +7.0 V
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$

DC V $\mathrm{V}_{\mathrm{C}}$ or Ground Current per Output Pin (ICC or I ${ }_{\text {GND }}$ )
Storage Temperature ( $T_{S T G}$ ) Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )

CDIP
$175^{\circ} \mathrm{C}$
PDIP
PD
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions

## 54AC/74AC151•54ACT/74ACT151 <br> 8-Input Multiplexer

## General Description

The 'AC/'ACT151 is a high-speed 8 -input digital multiplexer. It provides, in one package, the ability to select one line of data from up to eight sources. The 'AC/'ACT151 can be used as a universal function generator to generate any logic function of four variables. Both true and complementary outputs are provided.

Features

- Outputs source/sink 24 mA
- 'ACT151 has TTL-compatible inputs
- Standard Military Drawing (SMD)
-'AC151: 5962-87691
-'ACT151: 5962-88756

Ordering Code: See Section 8

Logic Symbol

| Pin Names | Description |
| :--- | :--- |
| $\mathrm{I}_{0}-\mathrm{I}_{7}$ | Data Inputs |
| $\mathrm{S}_{0}-\mathrm{S}_{2}$ | Select Inputs |
| $\overline{\mathrm{E}}$ | Enable Input |
| Z | Data Output |
| $\bar{Z}$ | Inverted Data Output |

[^18]
## Functional Description

The 'AC/'ACT151 is a logic implementation of a single pole, 8 -position switch with the switch position controlled by the state of three Select inputs, $\mathrm{S}_{0}, \mathrm{~S}_{1}, \mathrm{~S}_{2}$. Both true and complementary outputs are provided. The Enable input ( $\bar{E}$ ) is active LOW. When it is not activated, the complementary output is HIGH and the true output is LOW regardless of all other inputs. The logic function provided at the output is:
$Z=\bar{E} \bullet\left(I_{0} \bullet \bar{S}_{0} \bullet \bar{S}_{1} \bullet \bar{S}_{2}+I_{1} \bullet S_{0} \bullet \bar{S}_{1} \bullet \bar{S}_{2}+\right.$

$$
\begin{aligned}
& I_{2} \bullet \mathrm{~S}_{0} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{2}+I_{3} \bullet \mathrm{~S}_{0} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{2}+ \\
& I_{4} \bullet \mathrm{~S}_{0} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{2}+I_{5} \bullet \mathrm{~S}_{0} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{2}+ \\
& \left.I_{6} \bullet \mathrm{~S}_{0} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{2}+I_{7} \bullet \mathrm{~S}_{0} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{2}\right)
\end{aligned}
$$

## Logic Diagram

TL/F/9927-4
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
-0.5 V to +7.0 V
DC Input Diode Current ( $l_{\mathrm{I}}$ )

$$
\begin{array}{ll}
V_{1}=-0.5 V & -20 \mathrm{~mA} \\
V_{1}=V_{C C}+0.5 V & +20 \mathrm{~mA}
\end{array}
$$

DC Input Voltage ( $\mathrm{V}_{\mathrm{I}}$ )
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Diode Current (Iok)

$$
\begin{aligned}
& V_{O}=-0.5 \mathrm{~V} \\
& V_{O}=V_{C C}+0.5 \mathrm{~V}
\end{aligned}
$$

$$
-20 \mathrm{~mA}
$$

$$
+20 \mathrm{~mA}
$$

DC Output Voltage (VO)
DC Output Source or Sink Current (I) DC V ${ }_{C C}$ or Ground Current per Output Pin (ICc or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )

| CDIP | $175^{\circ} \mathrm{C}$ |
| :--- | :--- |
| PDIP | $140^{\circ} \mathrm{C}$ |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions

| Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) |  |
| :---: | :---: |
| 'AC | 2.0 V to 6.0 V |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage ( $\mathrm{V}_{1}$ ) | O to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage (V) | OV to $\mathrm{V}_{\mathrm{CC}}$ |
| Operating Temperature ( $\mathrm{T}_{\mathrm{A}}$ ) |  |
| 74AC/ACT | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| 54AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) |  |
| 'AC Devices |  |
| $\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\text {CC }}$ |  |
| $\mathrm{V}_{\text {CC }}$ @ 3.3V, $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$ | $125 \mathrm{mV} / \mathrm{ns}$ |
| Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) |  |
| 'ACT Devices |  |
| $\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V |  |
| $\mathrm{V}_{\mathrm{CC}}$ @ 4.5V,5.5V | $125 \mathrm{mV} / \mathrm{ns}$ |

## 54AC/74AC153 • 54ACT/74ACT153 Dual 4-Input Multiplexer

## General Description

The 'AC/'ACT153 is a high-speed dual 4 -input multiplexer with common select inputs and individual enable inputs for each section. It can select two lines of data from four sources. The two buffered outputs present data in the true (noninverted) form. In addition to multiplexer operation, the 'AC/ 'ACT153 can act as a function generator and generate any two functions of three variables.

Features

- Outputs source/sink 24 mA
- 'ACT153 has TTL-compatible inputs
- Standard Military Drawings (SMD)
- 'AC153: 5962-87625
- 'ACT153: 5962-87698

Ordering Code: See Section 8

## Functional Description

The 'AC/'ACT153 is a dual 4 -input multiplexer. It can select two bits of data from up to four sources under the control of the common Select inputs $\left(\mathrm{S}_{0}, \mathrm{~S}_{1}\right)$. The two 4 -input multiplexer circuits have individual active-LOW Enables ( $\bar{E}_{a}, \bar{E}_{b}$ ) which can be used to strobe the outputs indepedently. When the Enables ( $\bar{E}_{\mathrm{a}}, \overline{\mathrm{E}}_{\mathrm{b}}$ ) are HIGH, the corresponding outputs $Z_{a}, Z_{b}$ ) are forced LOW. The 'AC/'ACT153 is the logic implementation of a 2-pole, 4-position switch, where the position of the switch is determined by the logic levels supplied to the Select inputs. The logic equations for the outputs are shown below.

$$
\begin{aligned}
\mathrm{Z}_{\mathrm{a}}= & \overline{\mathrm{E}}_{\mathrm{a}} \bullet\left(\mathrm{l}_{0 \mathrm{a}} \bullet \overline{\mathrm{~S}}_{1} \bullet \overline{\mathrm{~S}}_{0}+\mathrm{I}_{1 \mathrm{a}} \bullet \overline{\mathrm{~S}}_{1} \bullet \mathrm{~S}_{0}+\right. \\
& \left.\mathrm{I}_{2 \mathrm{a}} \cdot \mathrm{~S}_{1} \bullet \mathrm{~S}_{0}+\mathrm{I}_{3 \mathrm{a}} \cdot \mathrm{~S}_{1} \bullet \mathrm{~S}_{0}\right) \\
\mathrm{Z}_{\mathrm{b}}= & \overline{\mathrm{E}}_{\mathrm{b}} \bullet\left(\mathrm{l}_{0 \mathrm{~b}} \bullet \overline{\mathrm{~S}}_{1} \bullet \overline{\mathrm{~S}}_{0}+\mathrm{I}_{1 \mathrm{~b}} \bullet \overline{\mathrm{~S}}_{1} \bullet \mathrm{~S}_{0}+\right. \\
& \left.\mathrm{I}_{2 \mathrm{~b}} \cdot \mathrm{~S}_{1} \bullet \mathrm{~S}_{0}+\mathrm{I}_{3 \mathrm{~b}} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{0}\right)
\end{aligned}
$$

## Logic Diagram

TL/F/9928-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
DC Input Diode Current ( $I_{\mid K}$ )
$V_{1}=-0.5 V$
$V_{1}=V_{C C}+0.5 V$
DC Input Voltage ( $\mathrm{V}_{1}$ )
DC Output Diode Current (lok)
$V_{O}=-0.5 \mathrm{~V}$
$V_{O}=V_{C C}+0.5 \mathrm{~V}$
DC Output Voltage (Vo)
DC Output Source
or Sink Current (lo)
DC VCC or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
CDIP
$175^{\circ} \mathrm{C}$
PDIP
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating

 ConditionsSupply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )

| 'AC | 2.0 V to 6.0 V |
| :--- | ---: |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage $\left(\mathrm{V}_{\mathrm{l}}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage $\left(\mathrm{V}_{\mathrm{O}}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Operating Temperature $\left(\mathrm{T}_{\mathrm{A}}\right)$ |  |
| $74 \mathrm{AC} /$ ACT | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| 54AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta t$ ) 'AC Devices $V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{C C}$ $\mathrm{V}_{\mathrm{CC}}$ @ 3.3V, 4.5V, 5.5V
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$\mathrm{V}_{\mathrm{CC}} @ 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$

## 54AC/74AC157 • 54ACT/74ACT157 <br> Quad 2-Input Multiplexer

## General Description

The 'AC/'ACT157 is a high-speed quad 2-input multiplexer. Four bits of data from two sources can be selected using the common Select and Enable inputs. The four outputs present the selected data in the true (noninverted) form. The 'AC/'ACT157 can also be used as a function generator.

## Features

■ Outputs source/sink 24 mA
■ 'ACT157 has TTL-compatible inputs

- Standard Military Drawing (SMD)
- 'AC157: 5962-89539
- 'ACT157: 5962-89688

Ordering Code: See Section 8

TL/F/9929-4

## Functional Description

The 'AC/'ACT157 is a quad 2-input multiplexer. It selects four bits of data from two sources under the control of a common Select input (S). The Enable input ( $\bar{E}$ ) is activeLOW. When $\bar{E}$ is HIGH, all of the outputs (Z) are forced LOW regardless of all other inputs. The 'AC/'ACT157 is the logic implementation of a 4 -pole, 2-position switch where the position of the switch is determined by the logic levels supplied to the Select input. The logic equations for the outputs are shown below:

$$
\begin{aligned}
& Z_{\mathrm{a}}=\overline{\mathrm{E}} \bullet\left(\mathrm{I}_{1 \mathrm{a}} \bullet \mathrm{~S}+\mathrm{I}_{\mathrm{oa}} \bullet \overline{\mathrm{~S}}\right) \\
& \mathrm{Z}_{\mathrm{b}}=\overline{\mathrm{E}} \bullet\left(\mathrm{I}_{1 \mathrm{~b}} \bullet \mathrm{~S}+\mathrm{I}_{\mathrm{ob}} \bullet \overline{\mathrm{~S}}\right) \\
& \mathrm{Z}_{\mathrm{c}}=\overline{\mathrm{E}} \cdot\left(\mathrm{I}_{1 \mathrm{c}} \bullet \mathrm{~S}+\mathrm{I}_{0 \mathrm{c}} \bullet \overline{\mathrm{~S}}\right) \\
& \mathrm{Z}_{\mathrm{d}}=\overline{\mathrm{E}} \cdot\left(\mathrm{I}_{1 \mathrm{~d}} \bullet \mathrm{~S}+\mathrm{I}_{0 \mathrm{~d}} \bullet \overline{\mathrm{~S}}\right)
\end{aligned}
$$

A common use of the 'AC/ACT157 is the moving of data from two groups of registers to four common output busses. The particular register from which the data comes is determined by the state of the Select input. A less obvious use is
as a function generator. The 'AC/'ACT157 can generate any four of the sixteen different functions of two variables with one variable common. This is useful for implementing gating functions.

Truth Table

| Inputs |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Outputs |  |  |  |  |
| $\bar{E}$ | S | I $_{\mathbf{O}}$ | $\mathbf{I}_{\mathbf{1}}$ | Z |
| H | X | X | X | L |
| L | H | X | L | L |
| L | H | X | H | H |
| L | L | L | X | L |
| L | L | H | X | H |

$H=$ HIGH Voltage Level
$L=$ LOW Voltage Level
$X=$ Immaterial

## Logic Diagram

TL/F/9929-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Rating (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

## Supply Voltage (VCC)

DC Input Diode Current ( $I_{\mathrm{IK}}$ )

$$
\begin{aligned}
& V_{1}=-0.5 \mathrm{~V} \\
& V_{1}=V_{C C}+0.5 \mathrm{~V}
\end{aligned}
$$

-0.5 V to +7.0 V

DC Output Diode Current (IOK)

$$
-20 \mathrm{~mA}
$$

$$
+20 \mathrm{~mA}
$$

DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )

$$
-0.5 \mathrm{~V} \text { to } \mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
$$

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V} \\
& \mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
\end{aligned}
$$

$$
-20 \mathrm{~mA}
$$

$$
+20 \mathrm{~mA}
$$

DC Output Voltage (Vo)
-0.5 V to to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$\pm 50 \mathrm{~mA}$
$\pm 50 \mathrm{~mA}$
$-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ or Sink Current (lo)
$175^{\circ} \mathrm{C}$
$140^{\circ} \mathrm{C}$

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )

| 'AC | 2.0 V to 6.0 V |
| :--- | ---: |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage $\left(\mathrm{V}_{\mathrm{l}}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage $\left(\mathrm{V}_{\mathrm{O}}\right)$ | 0 V to VCC |
| Operating Temperature $\left(\mathrm{T}_{\mathrm{A}}\right)$ |  |
| 74AC/ACT | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| 54AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Minimum Input Edge Rate $(\Delta \mathrm{V} / \Delta \mathrm{t})$
'AC Devices
$\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\mathrm{CC}}$
$V_{C C}$ @ 3.3V, 4.5V, 5.5V $125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate $(\Delta \mathrm{V} / \Delta \mathrm{t})$ 'ACT Devices
$\mathrm{V}_{\mathrm{IN}}$ from 0.8 V to 2.0 V
$\mathrm{V}_{\mathrm{CC}}$ @ $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$

## 54AC/74AC158•54ACT/74ACT158 Quad 2-Input Multiplexer

## General Description

The 'AC/'ACT158 is a high-speed quad 2-input multiplexer. It selects four bits of data from two sources using the common Select and Enable inputs. The four buffered outputs present the selected data in the inverted form. The 'AC/ 'ACT158 can also be used as a function generator.

Features
■ Outputs source/sink 24 mA

- 'ACT158 has TTL-compatible inputs
- Standard Military Drawing (SMD)
- 'AC158: 5962-89729
- 'ACT158: 5962-88755

Ordering Code: See Section 8

## Logic Symbols

IEE/IEC

| Pin Names | Description |
| :--- | :--- |
| $\mathrm{I}_{\mathrm{a}}-\mathrm{I}_{0 \mathrm{~d}}$ | Source 0 Data Inputs |
| $\mathrm{I}_{\mathrm{a}}-\mathrm{I}_{1 \mathrm{~d}}$ | Source 1 Data Inputs |
| $\overline{\mathrm{E}}^{\mathrm{S}}$ | Enable Input |
| S | Select Input |
| $\overline{\mathrm{Z}}_{\mathrm{a}}-\overline{\mathrm{Z}}_{\mathrm{d}}$ | Inverted Outputs |

## Functional Description

The 'AC/'ACT158 quad 2-input multiplexer selects four bits of data from two sources under the control of a common Select input ( S ) and presents the data in inverted form at the four outputs. The Enable input ( $\bar{E}$ ) is active-LOW. When $\overline{\mathrm{E}}$ is HIGH, all of the outputs ( $\overline{\mathrm{Z}}$ ) are forced HIGH regardless of all other inputs. The 'AC/'ACT158 is the logic implementation of a 4-pole, 2-position switch where the position of the switch is determined by the logic levels supplied to the Select input.
A common use of the 'AC/'ACT158 is the moving of data from two groups of registers to four common output busses. The particular register from which the data comes is determined by the state of the Select input. A less obvious use is as a function generator. The 'AC/'ACT158 can generate four functions of two variables with one variable common. This is useful for implementing gating functions.

Truth Table

| Inputs |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| $\bar{E}$ | $S$ | $I_{0}$ | $I_{\mathbf{1}}$ | $\bar{Z}$ |
| $H$ | $X$ | $X$ | $X$ | $H$ |
| L | L | L | $X$ | $H$ |
| L | L | $H$ | $X$ | $L$ |
| L | $H$ | $X$ | $L$ | $H$ |
| L | $H$ | $X$ | $H$ | L |

$H=$ HIGH Voltage Level
$\mathrm{L}=$ LOW Voltage Level
$X=$ Immaterial

## Logic Diagram

Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Rating (Note 1)
If Milltary/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )
DC Input Diode Current (l|k)
$V_{1}=-0.5 \mathrm{~V}$
$V_{1}=V_{C C}+0.5 \mathrm{~V}$
DC Input Voltage ( $\mathrm{V}_{1}$ )
DC Output Diode Current (lok)
$V_{O}=-0.5 \mathrm{~V}$
$V_{O}=V_{C C}+0.5 \mathrm{~V}$
DC Output Voltage (V)
DC Output Source
or Sink Current (lo)
DC VCC or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
CDIP $75^{\circ} \mathrm{C}$ PDIP $140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating

 ConditionsSupply Voltage (VCC)

| 'AC | 2.0 V to 6.0 V |
| :--- | ---: |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage $\left(V_{1}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage $\left(V_{\mathrm{O}}\right)$ | 0 V to VCC |
| Operating Temperature $\left(\mathrm{T}_{\mathrm{A}}\right)$ | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| $744 \mathrm{C} / \mathrm{ACT}$ | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'AC Devices $V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{C C}$ $\mathrm{V}_{\mathrm{CC}}$ @ $3.3 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$\mathrm{V}_{\mathrm{CC}}$ @ $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$

## 54AC/74AC161•54ACT/74ACT161 Synchronous Presettable Binary Counter

## General Description

The 'AC/'ACT161 are high-speed synchronous modulo-16 binary counters. They are synchronously presettable for application in programmable dividers and have two types of Count Enable inputs plus a Terminal Count output for versatility in forming synchronous multistage counters. The 'AC/ 'ACT161 has an asynchronous Master Reset input that overrides all other inputs and forces the outputs LOW.

## Features

- Synchronous counting and loading
- High-speed synchronous expansion
- Typical count rate of 125 MHz
- Outputs source/sink 24 mA

■ 'ACT161 has TTL-compatible inputs

- Standard Military Drawing (SMD)
- 'AC161: 5962-89561

Ordering Code: See Section 8

## Functional Description

The 'AC/'ACT161 count in modulo-16 binary sequence. From state 15 (HHHH) they increment to state 0 (LLLL). The clock inputs of all flip-flops are driven in parallel through a clock buffer. Thus all changes of the Q outputs (except due to Master Reset of the '161) occur as a result of, and synchronous with, the LOW-to-HIGH transition of the CP input signal. The circuits have four fundamental modes of operation, in order of precedence: asynchronous reset, parallel load, count-up and hold. Five control inputs-Master Reset, Parallel Enable ( $\overline{\mathrm{PE}}$ ), Count Enable Parallel (CEP) and Count Enable Trickle (CET)-determine the mode of operation, as shown in the Mode Select Table. A LOW signal on $\overline{\mathrm{MR}}$ overrides all other inputs and asynchronously forces all outputs LOW. A LOW signal on $\overline{\text { PE overrides counting and }}$ allows information on the Parallel Data $\left(P_{n}\right)$ inputs to be loaded into the flip-flops on the next rising edge of CP. With $\overline{\mathrm{PE}}$ and $\overline{\mathrm{MR}}$ HIGH, CEP and CET permit counting when both are HIGH. Conversely, a LOW signal on either CEP or CET inhibits counting.
The 'AC/'ACT161 use D-type edge-triggered flip-flops and changing the $\overline{\mathrm{PE}}, \mathrm{CEP}$ and CET inputs when the CP is in either state does not cause errors, provided that the recommended setup and hold times, with respect to the rising edge of CP, are observed.
The Terminal Count (TC) output is HIGH when CET is HIGH and counter is in state 15 . To implement synchronous multistage counters, the TC outputs can be used with the CEP and CET inputs in two different ways.
Figure 1 shows the connections for simple ripple carry, in which the clock period must be longer than the CP to TC delay of the first stage, plus the cumulative $\overline{\mathrm{CET}}$ to $\overline{\mathrm{TC}}$ delays of the intermediate stages, plus the $\overline{\mathrm{CET}}$ to CP setup time of the last stage. This total delay plus setup time sets the upper limit on clock frequency. For faster clock rates, the carry lookahead connections shown in Figure 2 are recommended. In this scheme the ripple delay through the intermediate stages commences with the same clock that causes the first stage to tick over from max to min in the Up mode, or min to max in the Down mode, to start its final cycle. Since this final cycle requires 16 clocks to complete, there is plenty of time for the ripple to progress through the intermediate stages. The critical timing that limits the clock period is the CP to $\overline{\mathrm{TC}}$ delay of the first stage plus the $\overline{\mathrm{CEP}}$ to CP setup time of the last stage. The $\overline{T C}$ output is subject
to decoding spikes due to internal race conditions and is therefore not recommended for use as a clock or asynchronous reset for flip-flops, registers or counters.
When the Output Enable ( $\overline{\mathrm{OE}}$ ) is LOW, the parallel data outputs $\mathrm{O}_{0}-\mathrm{O}_{3}$ are active and follow the flip-flop Q outputs. A HIGH signal on $\overline{O E}$ forces $\mathrm{O}_{0}-\mathrm{O}_{3}$ to the High Z state but does not prevent counting, loading or resetting.
Logic Equations: Count Enable $=$ CEP $\bullet$ CET $\bullet \overline{P E}$ $T C=Q_{0} \bullet Q_{1} \bullet Q_{2} \bullet Q_{3} \bullet C E T$

Mode Select Table

| $\overline{\text { PE }}$ | CET | CEP | Action on the Rising <br> Clock Edge ( |

## Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
DC Input Diode Current (IIK)
$V_{1}=-0.5 \mathrm{~V}$
$V_{1}=V_{C C}+0.5 V$

DC Input Voltage $\left(V_{1}\right)$
DC Output Diode Current (lok)
$V_{0}=-0.5 \mathrm{~V}$
$V_{O}=V_{C C}+0.5 V$
DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current (lo)
DC V $\mathrm{V}_{\mathrm{CC}}$ or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) $\begin{array}{ll}\text { CDIP } & 175^{\circ} \mathrm{C} \\ \text { PDIP } & 140^{\circ} \mathrm{C}\end{array}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) 'AC
2.0 V to 6.0 V
'ACT
4.5 V to 5.5 V

Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
Output Voltage (VO)
Operating Temperature $\left(T_{A}\right)$
74AC/ACT
54AC/ACT
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$

Minimum Input Edge Rate $(\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'AC Devices
$V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{C C}$
$V_{C C}$ @ 3.3V, 4.5V, 5.5V $125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$V_{C C} @ 4.5 \mathrm{~V}, 5.5 \mathrm{~V} \quad 125 \mathrm{mV} / \mathrm{ns}$

## 54AC／74AC163 • 54ACT／74ACT163 Synchronous Presettable Binary Counter

## General Description

The＇AC／＇ACT163 are high－speed synchronous modulo－16 binary counters．They are synchronously presettable for ap－ plication in programmable dividers and have two types of Count Enable inputs plus a Terminal Count output for versa－ tility in forming synchronous multistage counters．The＇AC／ ＇ACT163 has a Synchronous Reset input that overrides counting and parallel loading and allows the outputs to be simultaneously reset on the rising edge of the clock．

## Features

国 Synchronous counting and loading
－High－speed synchronous expansion
－Typical count rate of 125 MHz
－Outputs source／sink 24 mA
⿴囗＇ACT163 has TTL－compatible inputs
田 Standard Military Drawing（SMD）
－＇AC163：5962－89582

Ordering Code：See Section 8

## Functional Description

The 'AC/'ACT163 counts in modulo-16 binary sequence. From state $15(\mathrm{HHHH})$ it increments to state 0 (LLLL). The clock inputs of all flip-flops are driven in parallel through a clock buffer. Thus all changes of the Q outputs occur as a result of, and synchronous with, the LOW-to-HIGH transition of the CP input signal. The circuits have four fundamental modes of operation, in order of precedence: synchronous reset, parallel load, count-up and hold. Four control inputsSynchronous Reset ( $\overline{\mathrm{SR}}$ ), Parallel Enable ( $\overline{\mathrm{PE}})$, Count Enable Parallel (CEP) and Count Enable Trickle (CET)-determine the mode of operation, as shown in the Mode Select Table. A LOW signal on $\overline{\mathrm{SR}}$ overrides counting and parallel loading and allows all outputs to go LOW on the next rising edge of CP. A LOW signal on PE overrides counting and allows information on the Parallel Data $\left(P_{n}\right)$ inputs to be loaded into the flip-flops on the next rising edge of CP. With $\overline{\text { PE }}$ and $\overline{\text { SR }}$ HIGH, CEP and CET permit counting when both are HIGH. Conversely, a LOW signal on either CEP or CET inhibits counting.
The 'AC/'ACT163 uses D-type edge-triggered flip-flops and changing the $\overline{\mathrm{SR}}, \overline{\mathrm{PE}}, \mathrm{CEP}$ and CET inputs when the CP is in either state does not cause errors, provided that the recommended setup and hold times, with respect to the rising edge of CP, are observed.
The Terminal Count (TC) output is HIGH when CET is HIGH and counter is in state 15. To implement synchronous multistage counters, the TC outputs can be used with the CEP and CET inputs in two different ways.
Figure 1 shows the connections for simple ripple carry, in which the clock period must be longer than the CP to $\overline{T C}$ delay of the first stage, plus the cumulative $\overline{\mathrm{CET}}$ to $\overline{\mathrm{TC}}$ delays of the intermediate stages, plus the CET to CP setup time of the last stage. This total delay plus setup time sets the upper limit on clock frequency. For faster clock rates, the carry lookahead connections shown in Figure 2 are recommended. In this scheme the ripple delay through the intermediate stages commences with the same clock that causes the first stage to tick over from max to min in the Up mode, or min to max in the Down mode, to start its final cycle. Since this final cycle takes 16 clocks to complete, there is plenty of time for the ripple to progress through the intermediate stages. The critical timing that limits the clock period is the CP to $\overline{T C}$ delay of the first stage plus the $\overline{C E P}$ to CP setup time of the last stage. The $\overline{T C}$ output is subject
to decoding spikes due to internal race conditions and is therefore not recommended for use as a clock or asynchronous reset for flip-flops, registers or counters. For such applications, the Clocked Carry ( $\overline{\mathrm{CC}}$ ) output is provided. The $\overline{\mathrm{CC}}$ output is normally HIGH. When CEP, $\overline{\mathrm{CET}}$, and TC are LOW, the $\overline{C C}$ output will go LOW when the clock next goes LOW and will stay LOW until the clock goes HIGH again, as shown in the $\overline{\mathrm{CC}}$ Truth Table. When the Output Enable ( $\overline{\mathrm{OE}}$ ) is LOW, the parallel data outputs $\mathrm{O}_{0}-\mathrm{O}_{3}$ are active and follow the flip-flop Q outputs. A HIGH signal on OE forces $\mathrm{O}_{0}-\mathrm{O}_{3}$ to the High Z state but does not prevent counting, loading or resetting.
Logic Equations: Count Enable $=\mathrm{CEP} \bullet \mathrm{CET} \bullet \overline{\mathrm{PE}}$

$$
T C=Q_{0} \bullet Q_{1} \bullet Q_{2} \bullet Q_{3} \bullet C E T
$$

| PDIP | $140^{\circ} \mathrm{C}$ |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) 'AC
2.0 V to 6.0 V 'ACT
4.5 V to 5.5 V

## 54AC/74AC169•54ACT/74ACT169 4-Stage Synchronous Bidirectional Counter

## General Description

The 'AC/'ACT169 is fully synchronous 4-stage up/down counter. The 'AC/'ACT169 is a modulo-16 binary counter. It features a preset capability for programmable operation, carry lookahead for easy cascading and a U/D input to control the direction of counting. All state changes, whether in counting or parallel loading, are initiated by the LOW-toHIGH transition of the Clock.

## Features

- Synchronous counting and loading
- Built-In lookahead carry capability
- Presettable for programmable operation
- Outputs source/sink 24 mA
- 'ACT has TTL-compatible inputs

## Ordering Code: See Section 8

## Logic Symbol

## Logic Diagram

Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

## Functional Description

The 'AC/'ACT169 uses edge-triggered J-K-type flip-flops and have no constraints on changing the control or data input signals in either state of the Clock. The only requirement is that the various inputs attain the desired state at least a setup time before the rising edge of the clock and remain valid for the recommended hold time thereafter. The parallel load operation takes precedence over the other operations, as indicated in the Mode Select Table. When $\overline{\mathrm{PE}}$ is LOW, the data on the $\mathrm{P}_{0}-\mathrm{P}_{3}$ inputs enters the flip-flops on the next rising edge of the Clock. In order for counting to occur, both $\overline{\mathrm{CEP}}$ and $\overline{\mathrm{CET}}$ must be LOW and $\overline{\mathrm{PE}}$ must be HIGH; the U/D input then determines the direction of counting. The Terminal Count ( $\overline{\mathrm{TC}}$ ) output is normally HIGH and goes LOW, provided that CET is LOW, when a counter reaches zero in the Count Down mode or reaches 15 in the Count Up mode. The TC output state is not a function of the Count Enable Parallel ( $\overline{\mathrm{CEP}}$ ) input level. If an illegal state occurs, the 'AC169 will return to the legitimate sequence within two counts. Since the TC signal is derived by decoding the flip-flop states, there exists the possibility of decoding spikes on $\overline{\mathrm{TC}}$. For this reason the use of $\overline{\mathrm{TC}}$ as a clock signal is not recommended (see logic equations below).

1) Count Enable $=\overline{\mathrm{CEP}} \bullet \overline{\mathrm{CET}} \cdot \overline{\mathrm{PE}}$
2) $U p: \overline{T C}=Q_{0} \bullet Q_{1} \bullet Q_{2} Q_{3} \bullet(U p) \bullet \overline{C E T}$
3) Down: $\overline{T C}=\bar{Q}_{0} \bullet \bar{Q}_{1} \bullet \bar{Q}_{2} \bullet \bar{Q}_{3} \bullet($ Down $) \bullet \overline{\mathrm{CET}}$

Mode Select Table

| $\overline{\text { PE }}$ | CEP | CET | U/D | Action on Rising <br> Clock Edge |
| :---: | :---: | :---: | :---: | :--- |
| L | X | X | X | Load (P n to Q $_{n}$ ) |
| H | L | L | H | Count Up (Increment) |
| H | L | L | L | Count Down (Decrement) |
| H | H | X | X | No Change (Hold) |
| H | X | H | X | No Change (Hold) |

H = HIGH Voltage Level
L = LOW Voltage Level
$X=$ Immaterial

## State Diagrams

| Absolute Maximum Ratings (Note 1) |  |
| :---: | :---: |
| If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications. |  |
| Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) | -0.5 V to +7.0 V |
| DC Input Diode Current ( $\mathrm{I}_{1}$ ) |  |
| $V_{1}=-0.5 \mathrm{~V}$ | -20 mA |
| $V_{1}=V_{C C}+0.5 \mathrm{~V}$ | + 20 mA |
| DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ ) | -0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$ |
| DC Output Diode Current (IOK) |  |
| $\mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V}$ | -20 mA |
| $V_{O}=V_{C C}+0.5 \mathrm{~V}$ | + 20 mA |
| DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ ) | -0.5 V to to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$ |
| DC Output Source or Sink Current (lo) | $\pm 50 \mathrm{~mA}$ |
| DC V ${ }_{C C}$ or Ground Current per Output Pin (ICC or IGND) | $\pm 50 \mathrm{~mA}$ |
| Storage Temperature ( $\mathrm{T}_{\text {STG }}$ ) | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) |  |
| CDIP | $175^{\circ} \mathrm{C}$ |
| PDIP | $140^{\circ} \mathrm{C}$ |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )

| 'AC | 2.0 V to 6.0 V |
| :--- | ---: |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage $\left(\mathrm{V}_{1}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage $\left(\mathrm{V}_{\mathrm{O}}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |

Operating Temperature $\left(T_{A}\right)$

| $74 \mathrm{AC} / \mathrm{ACT}$ | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| :--- | :--- |
| $54 \mathrm{AC} / \mathrm{ACT}$ | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'AC Devices $\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\mathrm{CC}}$ $\mathrm{V}_{\mathrm{CC}}$ @ $3.3 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$\mathrm{V}_{\mathrm{CC}}$ @ $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$

## 54AC／74AC174 • 54ACT／74ACT174 Hex D Flip－Flop with Master Reset

## General Description

The＇AC／＇ACT174 is a high－speed hex D flip－flop．The de－ vice is used primarily as a 6－bit edge－triggered storage regis－ ter．The information on the D inputs is transferred to storage during the LOW－to－HIGH clock transition．The device has a Master Reset to simultaneously clear all flip－flops．

## Features

■ Outputs source／sink 24 mA
－＇ACT174 has TTL－compatible inputs
■ Standard Military Drawing（SMD）
—＇AC174：5962－87626
—＇ACT174：5962－87757
Ordering Code：See Section 8

Functional Description
The 'AC/'ACT174 consists of six edge-triggered $D$ flip-flops with individual $D$ inputs and Q outputs. The Clock (CP) and Master Reset (MR) are common to all flip-flops. Each D input's state is transferred to the corresponding flip-flop's output following the LOW-to-HIGH Clock (CP) transition. A LOW input to the Master Reset ( $\overline{\mathrm{MR}}$ ) will force all outputs LOW independent of Clock or Data inputs. The 'AC/ 'ACT174 is useful for applications where the true output only is required and the Clock and Master Reset are common to all storage elements.

Truth Table

| Inputs |  |  | Output |
| :---: | :---: | :---: | :---: |
| $\overline{M R}$ | CP | D | Q |
| L | X | X | L |
| H | - | H | H |
| H | - | L | L |
| H | L | X | Q |

$H=H I G H$ Voltage Level
L = LOW Voltage Level
X = Immaterial
$\Omega=$ LOW-to-HIGH Transition

## Logic Diagram

Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specifled devices are required, please contact the National Semiconductor Sales Office/Distributors for avallability and specifications.

\end{aligned}
$$

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating Conditions

Supply Voltage (VCC)

| 'AC | 2.0 V to 6.0 V |
| :--- | ---: |
| 'ACT | 4.5 V to 5.5 V |

## 54AC/74AC175 • 54ACT/74ACT175 Quad D Flip-Flop

## General Description

The 'AC/'ACT175 is a high-speed quad D flip-flop. The device is useful for general flip-flop requirements where clock and clear inputs are common. The information on the D inputs is stored during the LOW-to-HIGH clock transition. Both true and complemented outputs of each flip-flop are provided. A Master Reset input resets all flip-flops, independent of the Clock or D inputs, when LOW.

## Features

■ Edge-triggered D-type inputs
a Buffered positive edge-triggered clock

- Asynchronous common reset

■ True and complement output
国 Outputs source/sink 24 mA

- 'ACT175 has TTL-compatible inputs
- Standard Military Drawing (SMD)
- 'AC175: 5962-89552
— 'ACT175: 5962-89693

Ordering Code: See Section 8

| Pin Names | Description |
| :--- | :--- |
| $D_{0}-D_{3}$ | Data Inputs |
| $C P$ | Clock Pulse Input |
| $\overline{M R}$ | Master Reset Input |
| $Q_{0}-Q_{3}$ | True Outputs |
| $\bar{Q}_{0}-\bar{Q}_{3}$ | Complement Outputs |

Functional Description
The 'AC/'ACT175 consists of four edge-triggered D flipflops with individual $D$ inputs and $Q$ and $\bar{Q}$ outputs. The Clock and Master Reset are common. The four flip-flops will store the state of their individual $D$ inputs on the LOW-toHIGH clock (CP) transition, causing individual $Q$ and $\bar{Q}$ outputs to follow. A LOW input on the Master Reset (MR) will force all $Q$ outputs LOW and $\bar{Q}$ outputs HIGH independent of Clock or Data inputs. The 'AC/'ACT175 is useful for general logic applications where a common Master Reset and Clock are acceptable.

Truth Table

| Inputs | Outputs |  |
| :---: | :---: | :---: |
| $@ \mathbf{t}_{\mathbf{n}}, \overline{\mathbf{M R}}=\mathbf{H}$ |  | $@ \mathbf{t}_{\mathrm{n}+1}$ |
| $\mathbf{D}_{\mathbf{n}}$ | $\mathbf{Q}_{\mathbf{n}}$ | $\overline{\mathbf{Q}}_{\mathrm{n}}$ |
| $L$ | $L$ | $H$ |
| $H$ | $H$ | $L$ |

$H=$ HIGH Voltage Level
L = LOW Voltage Level
$t_{n}=$ Bit Time before Clock Pulse $\mathrm{t}_{\mathrm{n}+1}=$ Bit Time after Clock Pulse

## Logic Diagram

TL/F/9936-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

## Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
DC Input Diode Current ( $l_{\mathrm{K}}$ )
$V_{1}=-0.5 \mathrm{~V}$
$V_{1}=V_{C C}+0.5 \mathrm{~V}$
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
DC Output Diode Current (lok)
$\mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V}$
$\mathrm{V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source
or Sink Current (lo)
DC V ${ }_{C C}$ or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )

| CDIP | $175^{\circ} \mathrm{C}$ |
| :--- | :--- |
| PDIP | $140^{\circ} \mathrm{C}$ |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating Conditions

| Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) |  |
| :---: | :---: |
| 'AC | 2.0 V to 6.0 V |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage ( $\mathrm{V}_{1}$ ) | OV to $\mathrm{V}_{\mathrm{Cc}}$ |
| Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ ) | O to $\mathrm{V}_{\mathrm{Cc}}$ |
| Operating Temperature ( $\mathrm{T}_{\mathrm{A}}$ ) |  |
| 74AC/ACT | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| 54AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) |  |
| 'AC Devices |  |
| $\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\text {CC }}$ |  |
| $\mathrm{V}_{\mathrm{CC}}$ @ 3.3V, $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$ | $125 \mathrm{mV} / \mathrm{ns}$ |
| Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) |  |
| 'ACT Devices |  |
| $\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V |  |
| $\mathrm{V}_{\mathrm{CC}} @ 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$ | $125 \mathrm{mV} / \mathrm{ns}$ |

## 54AC/74AC191

Up/Down Counter with Preset and Ripple Clock

## General Description

The 'AC191 is a reversible modulo 16 binary counter. It features synchronous counting and asynchronous presetting. The preset feature allows the 'AC191 to be used in programmable dividers. The Count Enable input, the Terminal Count output and the Ripple Clock output make possible a variety of methods of implementing multistage counters. In the counting modes, state changes are initiated by the rising edge of the clock.

## Features

- High speed- 133 MHz typical count frequency
- Synchronous counting
- Asynchronous parallel load
- Cascadable
- Outputs source/sink 24 mA

## Ordering Code: See Section 8

## Functional Description

The 'AC191 is a synchronous up/down counter. The 'AC191 is organized as a 4-bit binary counter. It contains four edge-triggered flip-flops with internal gating and steering logic to provide individual preset, count-up and countdown operations.
Each circuit has an asynchronous parallel load capability permitting the counter to be preset to any desired number. When the Parallel Load ( $\overline{\mathrm{PL}})$ input is LOW, information present on the Parallel Load inputs $\left(\mathrm{P}_{0}-\mathrm{P}_{3}\right)$ is loaded into the counter and appears on the Q outputs. This operation overrides the counting functions, as indicated in the Mode Se lect Table.
A HIGH signal on the $\overline{C E}$ input inhibits counting. When $\overline{C E}$ is LOW, internal state changes are initiated synchronously by the LOW-to-HIGH transition of the clock input. The direction of counting is determined by the $\bar{U} / \mathrm{D}$ input signal, as indicated in the Mode Select Table. $\overline{C E}$ and U/D can be changed with the clock in either state, provided only that the recommended setup and hold times are observed.
Two types of outputs are provided as overflow/underflow indicators. The terminal count (TC) output is normally LOW. It goes HIGH when the circuits reach zero in the count down mode or 15 in the count up mode. The TC output will then remain HIGH until a state change occurs, whether by counting or presetting or until $\bar{U} / D$ is changed. The TC output should not be used as a clock signal because it is subject to decoding spikes.
The TC signal is also used internally to enable the Ripple Clock ( $\overline{\mathrm{RC}}$ ) output. The $\overline{\mathrm{RC}}$ output is normally HIGH. When $\overline{\mathrm{CE}}$ is LOW and TC is HIGH, $\overline{\mathrm{RC}}$ output wil go LOW when the clock next goes LOW and will stay LOW until the clock goes HIGH again. This feature simplifies the design of multistage counters, as indicated in Figures $A$ and $B$. In Figure $A$, each $\overline{\mathrm{RC}}$ output is used as the clock input for the next higher stage. This configuration is particularly advantageous when the clock source has a limited drive capability, since it drives only the first stage. To prevent counting in all stages it is only necessary to inhibit the first stage, since a HIGH signal on $\overline{\mathrm{CE}}$ inhibits the $\overline{\mathrm{RC}}$ output pulse, as indicated in the $\overline{\mathrm{RC}}$ Truth Table. A disadvantage of this configuration, in some applications, is the timing skew between state changes in the first and last stages. This represents the cumulative delay of the clock as it ripples through the preceding stages.
A method of causing state changes to occur simultaneously in all stages is shown in Figure B. All clock inputs are driven in parallel and the $\overline{\mathrm{RC}}$ outputs propagate the carry/borrow signals in ripple fashion. In this configuration the LOW state duration of the clock must be long enough to allow the neg-ative-going edge of the carry/borrow signal to ripple through to the last stage before the clock goes HIGH. There is no such restriction on the HIGH state duration of the clock, since the $\overline{R C}$ output of any device goes HIGH shortly after its CP input goes HIGH.
The configuration shown in Figure $C$ avoids ripple delays and their associated restrictions. The $\overline{\mathrm{CE}}$ input for a given stage is formed by combining the TC signals from all the preceding stages. Note that in order to inhibit counting an enable signal must be included in each carry gate. The simple inhibit scheme of Figures $A$ and $B$ doesn't apply, because the TC output of a given stage is not affected by its own $\overline{\mathrm{CE}}$.

Logic Diagram

Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (VCC)
DC Input Diode Current ( $I_{\text {K }}$ )

$$
\begin{aligned}
& V_{1}=-0.5 \mathrm{~V} \\
& V_{1}=V_{C C}+0.5 \mathrm{~V}
\end{aligned}
$$

DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
DC Output Diode Current (IOK)
$\mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V}$
$V_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current (IO)
DC V $C C$ or Ground Current per Output Pin (Icc or IGND)
Storage Temperature (TSTG) Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
$175^{\circ} \mathrm{C}$ PDIP

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating

 Conditions| Supply Voltage $\left(V_{C C}\right)$ | 2.0 V to 6.0 V |
| :--- | ---: |
| Input Voltage $\left(\mathrm{V}_{1}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage $\left(\mathrm{V}_{\mathrm{O}}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Operating Temperature $\left(\mathrm{T}_{\mathrm{A}}\right)$ |  |
| $74 \mathrm{AC} /$ ACT | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| $54 \mathrm{AC} /$ ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'AC Devices $\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\mathrm{CC}}$ $\mathrm{V}_{\mathrm{CC}}$ @ 3.3V $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate $(\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$\mathrm{V}_{\mathrm{CC}} @ 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$

## DC Characteristics for 'AC Family Devices

## 54AC/74AC240•54ACT/74ACT240

## Octal Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'AC/'ACT240 is an octal buffer and line driver designed to be employed as a memory address driver, clock driver and bus oriented transmitter or receiver which provides improved PC board density.

## Features

I Inverting TRI-STATE outputs drive bus lines or buffer memory address registers
( Outputs source/sink 24 mA

- 'ACT240 has TTL-compatible inputs
m Standard Military Drawing (SMD)
— 'AC240: 5962-87550
- 'ACT240: 5962-87759

Ordering Code: See Section 8

H = HIGH Voltage Level
L = LOW Voltage Level
$X=$ Immaterial
$Z=$ High Impedance

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )
DC Input Diode Current ( $I_{1 K}$ )

$$
\begin{aligned}
& V_{1}=-0.5 V \\
& V_{1}=V_{C C}+0.5 V
\end{aligned}
$$

DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
DC Output Diode Current (loK)

| $V_{\mathrm{O}}=-0.5 \mathrm{~V}$ | -20 mA |
| :--- | ---: |
| $\mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$ | +20 mA |
| DC Output Voltage $\left(\mathrm{V}_{\mathrm{O}}\right)$ | -0.5 V to to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$ |
| DC Output Source |  |
| or Sink Current ( $\mathrm{l}_{\mathrm{O}}$ ) | $\pm 50 \mathrm{~mA}$ |
| DC $\mathrm{V}_{\mathrm{CC}}$ or Ground Current |  |
| per Output Pin (lCC or $\left.\mathrm{I}_{\mathrm{GND}}\right)$ | $\pm 50 \mathrm{~mA}$ |
| Storage Temperature (TSTG) | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Junction Temperature ( $\left.\mathrm{T}_{\mathrm{J}}\right)$ |  |
| CDIP | $175^{\circ} \mathrm{C}$ |
| PDIP | $140^{\circ} \mathrm{C}$ |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating

 ConditionsSupply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )

| 'AC | 2.0 V to 6.0 V |
| :--- | ---: |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage $\left(\mathrm{V}_{\mathrm{V}}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage $\left(\mathrm{V}_{\mathrm{O}}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |

Operating Temperature $\left(T_{A}\right)$

## 74AC/ACT

$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$

## 54AC/74AC241 • 54ACT/74ACT241 Octal Buffer/Line Driver with TRI-STATE® Outputs

## General Description

The 'AC/'ACT241 is an octal buffer and line driver designed to be employed as a memory address driver, clock driver and bus-oriented transmitter or receiver which provides improved PC board density.

## Features

- Non-inverting TRI-STATE outputs drive bus lines or buffer memory address registers
- Outputs source/sink 24 mA
- 'ACT241 has TTL-compatible inputs
- Standard Military Drawing (SMD)
- 'AC241: 5962-87551
— 'ACT241: 5962-89847

Ordering Code: See Section 8
Logic Symbol

[^36]Absolute Maximum Rating (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
DC Input Diode Current ( $l_{\mathrm{IK}}$ )
$V_{1}=-0.5 \mathrm{~V}$
$V_{1}=V_{C C}+0.5 V$
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
-0.5 V to +7.0 V

DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
DC Output Diode Current (lok)

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V} \\
& \mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
\end{aligned}
$$

$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current (lo)
DC VCC or Ground Current per Output Pin (ICC or $I_{G N D}$ )
Storage Temperature ( $\mathrm{T}_{\mathrm{STG}}$ )
Junction Temperature ( $T_{J}$ ) CDIP
$175^{\circ} \mathrm{C}$ PDIP

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )

| 'AC | 2.0 V to 6.0 V |
| :--- | ---: |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage $\left(\mathrm{V}_{1}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage $\left(\mathrm{V}_{\mathrm{O}}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Operating Temperature $\left(\mathrm{T}_{\mathrm{A}}\right)$ |  |
| 74AC/ACT | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| 54AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'AC Devices $V_{I N}$ from $30 \%$ to $70 \%$ of $V_{C C}$ $\mathrm{V}_{\mathrm{CC}}$ @ $3.3 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$V_{C C}$ @ 4.5V, $5.5 \mathrm{~V} \quad 125 \mathrm{mV} / \mathrm{ns}$

## 54AC/74AC244 • 54ACT/74ACT244 Octal Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'AC/'ACT244 is an octal buffer and line driver designed to be employed as a memory address driver, clock driver and bus-oriented transmitter/receiver which provides improved PC board density.

## Features

TRI-STATE outputs drive bus lines or buffer memory address registers

- Outputs source/sink 24 mA
- 'ACT244 has TTL-compatible inputs
- Standard Military Drawing (SMD)
- 'AC244: 5962-87552
- 'ACT244: 5962-87760

Ordering Code: See Section 8

## Logic Symbol

IEEE/IEC

Pin Assignment for DIP, Flatpak and SOIC

TL/F/9943-2

TL/F/9943-3

$H=$ HIGH Voltage Level
L = LOW Voltage Level
$\mathrm{X}=$ Immaterial
$Z=$ High Impedance

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

## Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )

DC Input Diode Current (IIK)
$V_{1}=-0.5 \mathrm{~V}$
$V_{1}=V_{C C}+0.5 \mathrm{~V}$

DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
DC Output Diode Current (lok)
$V_{0}=-0.5 \mathrm{~V}$
$V_{O}=V_{C C}+0.5 \mathrm{~V}$
DC Output Voltage (V)
DC Output Source or Sink Current (IO)
-0.5 V to +7.0 V

$$
\begin{aligned}
&-20 \mathrm{~mA} \\
&+ 20 \mathrm{~mA} \\
&-0.5 \mathrm{~V} \text { to } \mathrm{V} \mathrm{CC}+0.5 \mathrm{~V} \\
&-20 \mathrm{~mA} \\
&+20 \mathrm{~mA}
\end{aligned}
$$

-0.5 V to to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$\pm 50 \mathrm{~mA}$
DC VCC or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
$175^{\circ} \mathrm{C}$
PDIP
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )
'AC
'ACT
Input Voltage ( $\mathrm{V}_{1}$ )

## 54AC/74AC245 • 54ACT/74ACT245 Octal Bidirectional Transceiver with TRI-STATE ${ }^{\circledR}$ Inputs/Outputs

## General Description

The 'AC/'ACT245 contains eight non-inverting bidirectional buffers with TRI-STATE outputs and is intended for bus-oriented applications. Current sinking capability is 24 mA at both the $A$ and $B$ ports. The Transmit/Receive (T/信) input determines the direction of data flow through the bidirectional transceiver. Transmit (active-HIGH) enables data from A ports to B ports; Receive (active-LOW) enables data from B ports to A ports. The Output Enable input, when HIGH, disables both A and B ports by placing them in a HIGH Z condition.

Features

- Noninverting buffers
- Bidirectional data path
- A and B outputs source/sink 24 mA
- 'ACT245 has TTL-compatible inputs
- Standard Military Drawing (SMD)
_ 'AC245: 5962-87758
- 'АСТ245: 5962-87663

Ordering Code: See Section 8

## Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
-0.5 V to +7.0 V
DC Input Diode Current ( $l_{\mid K}$ )

$$
\begin{aligned}
& V_{1}=-0.5 \mathrm{~V} \\
& V_{1}=V_{C C}+0.5 \mathrm{~V}
\end{aligned}
$$

$$
\begin{aligned}
& -20 \mathrm{~mA} \\
& +20 \mathrm{~mA}
\end{aligned}
$$

DC Input Voltage ( $\mathrm{V}_{1}$ )

$$
-0.5 \mathrm{~V} \text { to } \mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
$$

DC Output Diode Current (lok)
$V_{O}=-0.5 \mathrm{~V}$
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
-0.5 V to to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$\pm 50 \mathrm{~mA}$
or Sink Current (lo)
DC V $C C$ or Ground Current per Output Pin (ICC or IGND)
$\pm 50 \mathrm{~mA}$
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
$175^{\circ} \mathrm{C}$ PDIP
$140^{\circ} \mathrm{C}$

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage (VCC)
'AC
2.0 V to 6.0 V
'ACT
4.5 V to 5.5 V

Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
Operating Temperature $\left(T_{A}\right)$ 74AC/ACT
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
54AC/ACT
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Minimum Input Edge Rate $(\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'AC Devices
$V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{C C}$
$V_{C C}$ @ 3.3V, 4.5V, $5.5 \mathrm{~V} \quad 125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate $(\Delta V / \Delta t)$
'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$\mathrm{V}_{\mathrm{CC}} @ 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$

## 54AC/74AC251 • 54ACT/74ACT251 8-Input Multiplexer with TRI-STATE ${ }^{\circledR}$ Output

## General Description

The 'AC/'ACT251 is a high-speed 8 -input digital multiplexer. It provides, in one package, the ability to select one bit of data from up to eight sources. It can be used as universal function generator to generate any logic function of four variables. Both true and complementary outputs are provided.

## Features

- Multifunctional capability
- On-chip select logic decoding
- Inverting and noninverting TRI-STATE outputs
- Outputs source/sink 24 mA
- 'ACT251 has TTL-compatible inputs
- Standard Military Drawing (SMD)
- 'AC251: 5962-87692
- 'ACT251: 5962-89599

Ordering Code: See Section 8

Pin Assignment for LCC
$\bar{z} \quad \mathrm{ZNC} \mathrm{I}_{0} \mathrm{I}_{1}$

TL/F/9945-4

## Functional Description

This device is a logical implementation of a single-pole, 8 -position switch with the switch position controlled by the state of three Select inputs, $\mathrm{S}_{0}, \mathrm{~S}_{1}, \mathrm{~S}_{2}$. Both true and complementary outputs are provided. The Output Enable input $(\overline{\mathrm{OE}})$ is active LOW. When it is activated, the logic function provided at the output is:

$$
\begin{aligned}
\mathrm{Z}=\overline{\mathrm{OE}} \bullet & \left(I_{0} \bullet \overline{\mathrm{~S}}_{0} \bullet \overline{\mathrm{~S}}_{1} \bullet \overline{\mathrm{~S}}_{2}+I_{1} \bullet \mathrm{~S}_{0} \bullet \overline{\mathrm{~S}}_{1} \bullet \overline{\mathrm{~S}}_{2}+\right. \\
& I_{2} \bullet \overline{\mathrm{~S}}_{0} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{2}+I_{3} \bullet \mathrm{~S}_{0} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{2}+ \\
& I_{4} \bullet \overline{\mathrm{~S}}_{0} \bullet \overline{\mathrm{~S}}_{1} \bullet \mathrm{~S}_{2}+I_{5} \bullet \mathrm{~S}_{0} \bullet \overline{\mathrm{~S}}_{1} \bullet \mathrm{~S}_{2}+ \\
& \left.I_{6} \bullet \overline{\mathrm{~S}}_{0} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{2}+I_{7} \bullet \mathrm{~S}_{0} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{2}\right)
\end{aligned}
$$

When the Output Enable is HIGH, both outputs are in the high impedance (High Z) state. This feature allows multiplexer expansion by tying the outputs of up to 128 devices together. When the outputs of the TRI-STATE devices are tied together, all but one device must be in the high impedance state to avoid high currents that would exceed the maximum ratings. The Output Enable signals should be designed to ensure there is no overlap in the active-LOW portion of the enable voltages.

Truth Table

| Inputs |  |  |  |  | Outputs |  |

## 54AC/74AC253 • 54ACT/74ACT253 Dual 4-Input Multiplexer with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'AC/'ACT253 is a dual 4-input multiplexer with TRISTATE outputs. It can select two bits of data from four sources using common select inputs. The outputs may be individually switched to a high impedance state with a HIGH on the respective Output Enable ( $\overline{\mathrm{OE}}$ ) inputs, allowing the outputs to interface directly with bus oriented systems.

## Features

- Multifunction capability
- Noninverting TRI-STATE outputs

■ Outputs source/sink 24 mA

- 'ACT253 has TTL-compatible inputs
- Standard Military Drawing (SMD)
— 'AC253: 5962-87693
- 'АСТ253: 5962-87761

Ordering Code: See Section 8

## Functional Description

The 'AC/'ACT253 contains two identical 4-input multiplexers with TRI-STATE outputs. They select two bits from four sources selected by common Select inputs ( $\mathrm{S}_{0}, \mathrm{~S}_{1}$ ). The 4input multiplexers have individual Output Enable ( $\overline{\mathrm{OE}}_{\mathrm{a}}, \overline{\mathrm{OE}}_{\mathrm{b}}$ ) inputs which, when HIGH, force the outputs to a high impedance (High Z) state. This device is the logic implementation of a 2-pole, 4-position switch, where the position of the switch is determined by the logic levels supplied to the two select inputs. The logic equations for the outputs are shown:

$$
\begin{aligned}
& \mathrm{Z}_{\mathrm{a}}=\overline{\mathrm{OE}}_{\mathrm{a}} \circ\left(\mathrm{l}_{0 \mathrm{a}} \circ \overline{\mathrm{~S}}_{1} \circ \overline{\mathrm{~S}}_{0}+\mathrm{I}_{1 \mathrm{a}} \circ \overline{\mathrm{~S}}_{1} \bullet \mathrm{~S}_{0}+\right. \\
& \left.I_{2 a} \bullet S_{1} \bullet \bar{S}_{0}+I_{3 a} \circ S_{1} \bullet S_{0}\right) \\
& \mathrm{Z}_{\mathrm{b}}=\overline{\mathrm{OE}}_{\mathrm{b}} \bullet\left(\mathrm{l}_{0 \mathrm{~b}} \bullet \overline{\mathrm{~S}}_{1} \bullet \overline{\mathrm{~S}}_{0}+\mathrm{I}_{1 \mathrm{~b}} \bullet \overline{\mathrm{~S}}_{1} \bullet \mathrm{~S}_{0}+\right. \\
& \left.\mathrm{I}_{2 b} \bullet \mathrm{~S}_{1} \bullet \overline{\mathrm{~S}}_{0}+\mathrm{I}_{3 \mathrm{~b}} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{0}\right)
\end{aligned}
$$

If the outputs of TRI-STATE devices are tied together, all but one device must be in the high impedance state to avoid high currents that would exceed the maximum ratings. Designers should ensure that Output Enable signals to TRISTATE devices whose outputs are tied together are designed so that there is no overlap.

## Truth Table

| Select <br> Inputs |  | Data Inputs |  |  |  | Output <br> Enable | Outputs |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

\end{array}
$$

-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$

Note 1: Absotute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## 54AC/74AC257•54ACT/74ACT257 <br> Quad 2-Input Multiplexer with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'AC/'ACT257 is a quad 2 -input multiplexer with TRISTATE outputs. Four bits of data from two sources can be selected using a Common Data Select input. The four outputs present the selected data in true (noninverted) form. The outputs may be switched to a high impedance state by placing a logic HIGH on the common Output Enable ( $\overline{\mathrm{OE}}$ ) input, allowing the outputs to interface directly with bus-oriented systems.

## Features

■ Multiplexer expansion by tying outputs together

- Noninverting TRI-STATE outputs
- Outputs source/sink 24 mA
- 'ACT257 has TTL-compatible inputs
- Standard Military Drawing (SMD)
- 'AC257: 5962-88703
— 'АСТ257: 5962-89689

Ordering Code: See Section 8

## Logic Symbols

TL/F/9949-2

| Pin Names | Description |
| :--- | :--- |
| S | Common Data Select Input |
| $\overline{\mathrm{OE}}$ | TRI-STATE Output Enable Input |
| $\mathrm{I}_{0 \mathrm{a}}-\mathrm{I}_{0 \mathrm{~d}}$ | Data Inputs from Source 0 |
| $\mathrm{I}_{1 \mathrm{a}}-I_{1 \mathrm{~d}}$ | Data Inputs from Source 1 |
| $\mathrm{Z}_{\mathrm{a}}-\mathrm{Z}_{\mathrm{d}}$ | TRI-STATE Multiplexer Outputs |

## Connection Diagrams

Pin Assignment for LCC

TL/F/9949-4

## Functional Description

The 'AC/'ACT257 is quad 2-input multiplexer with TRISTATE outputs. It selects four bits of data from two sources under control of a Common Data Select input. When the Select input is LOW, the $\mathrm{I}_{0 x}$ inputs are selected and when Select is HIGH, the $l_{1 x}$ inputs are selected. The data on the selected inputs appears at the outputs in true (noninverted) form. The device is the logic implementation of a 4-pole, 2position switch where the position of the switch is determined by the logic levels supplied to the Select input. The logic equations for the outputs are shown below:

$$
\begin{aligned}
& \mathrm{Z}_{\mathrm{a}}=\overline{\mathrm{OE}} \bullet\left(1_{1 \mathrm{a}} \bullet \mathrm{~S}+\mathrm{I}_{0 \mathrm{a}} \bullet \overline{\mathrm{~S}}\right) \\
& \mathrm{Z}_{\mathrm{b}}=\overline{\mathrm{OE}} \bullet\left(1_{1 \mathrm{~b}} \bullet \mathrm{~S}+\mathrm{I}_{0 \mathrm{~b}} \bullet \overline{\mathrm{~S}}\right) \\
& \mathrm{Z}_{\mathrm{c}}=\overline{\mathrm{OE}} \bullet\left(1_{1 \mathrm{c}} \bullet \mathrm{~S}+\mathrm{I}_{0 \mathrm{c}} \bullet \overline{\mathrm{~S}}\right) \\
& \mathrm{Z}_{\mathrm{d}}=\overline{\mathrm{OE}} \bullet\left(1_{1 \mathrm{~d}} \bullet \mathrm{~S}+\mathrm{I}_{0 \mathrm{~d}} \bullet \overline{\mathrm{~S}}\right)
\end{aligned}
$$

When the Output Enable ( $\overline{\mathrm{OE}}$ ) is HIGH, the outputs are forced to a high impedance state. If the outputs are tied together, all but one device must be in the high impedance state to avoid high currents that would exceed the maxi-
mum ratings. Designers should ensure the Output Enable signals to TRI-STATE devices whose outputs are tied together are designed so there is no overlap.

Truth Table

| Output <br> Enable | Select <br> Input | Data <br> Inputs |  | Outputs |
| :---: | :---: | :---: | :---: | :---: |
| $\overline{\mathrm{OE}}$ | S | $\mathrm{I}_{\mathbf{0}}$ | $\mathrm{I}_{\mathbf{1}}$ | Z |
| H | X | X | X | Z |
| L | H | X | L | L |
| L | H | X | H | H |
| L | L | L | X | L |
| L | L | H | X | H |

H = HIGH Voltage Level
L = LOW Voltage Level
$\mathrm{X}=$ Immaterial
Z $=$ High Impedance

## Logic Diagram

TL/F/9949-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
-0.5 V to 7.0 V
DC Input Diode Current ( $I_{\mathrm{IK}}$ )

$$
\begin{aligned}
& V_{1}=-0.5 \mathrm{~V} \\
& V_{1}=V_{C C}+0.5 V
\end{aligned}
$$

$$
-20 \mathrm{~mA}
$$

$$
+20 \mathrm{~mA}
$$

DC Input Voltage ( $\mathrm{V}_{\mathrm{I}}$ )
DC Output Diode Current (IOK)
$V_{0}=-0.5 \mathrm{~V}$
$\mathrm{V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Voltage (Vo)
DC Output Source or Sink Current (lo)
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$

$$
\begin{aligned}
& -20 \mathrm{~mA} \\
& +20 \mathrm{~mA}
\end{aligned}
$$

-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$

DC V $V_{C C}$ or Ground Current
Per Output Pin (ICC or IGND)
$\pm 50 \mathrm{~mA}$
Storage Temperature (TSTG)
$-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
CDIP
$175^{\circ} \mathrm{C}$
$140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating

 Conditions| Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) |  |
| :---: | :---: |
| 'AC | 2.0 V to 6.0 V |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ ) | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ ) | O to $\mathrm{V}_{\mathrm{CC}}$ |
| Operating Temperature ( $\mathrm{T}_{\mathrm{A}}$ ) |  |
| 74AC/ACT | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| 54AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) |  |
| 'AC Devices |  |
| $\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\text {CC }}$ |  |
| $\mathrm{V}_{\mathrm{CC}}$ @ 3.3V, $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$ | $125 \mathrm{mV} / \mathrm{ns}$ |
| Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) |  |
| 'ACT Devices |  |
| $\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V |  |
| $\mathrm{V}_{\mathrm{CC}}$ @ 4.5V, 5.5 V | $125 \mathrm{mV} / \mathrm{ns}$ |

## 54AC/74AC258 • 54ACT/74ACT258 Quad 2-Input Multiplexer with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'AC/'ACT258 is a quad 2 -input multiplexer with TRISTATE outputs. Four bits of data from two sources can be selected using a common data select input. The four outputs present the selected data in the complement (inverted) form. The outputs may be switched to a high impedance state with a HIGH on the common Output Enable ( $\overline{\mathrm{OE}})$ input, allowing the outputs to interface directly with bus-oriented systems.

## Features

- Multiplexer expansion by tying outputs together
- Inverting TRI-STATE outputs
- Outputs source/sink 24 mA
- 'ACT258 has TTL-compatible inputs
- Standard Military Drawing (SMD)
— 'ACT258: 5962-88704

Ordering Code: See Section 8

${ }^{\circ}{ }_{o d} \bar{Z}_{c} N C I_{1 c} b_{c}$

Functional Description
The 'AC/'ACT258 is a quad 2 -input multiplexer with TRISTATE outputs. It selects four bits of data from two sources under control of a common Select input (S). When the Select input is LOW, the $l_{0 x}$ inputs are selected and when Se lect is HIGH, the $I_{1 x}$ inputs are selected. The data on the selected inputs appears at the outputs in inverted form. The 'AC/'ACT258 is the logic implementation of a 4-pole, 2-position switch where the position of the switch is determined by the logic levels supplied to the Select input. The logic equations for the outputs are shown below:

$$
\begin{aligned}
& \bar{Z}_{\mathrm{a}}=\overline{\mathrm{OE}} \bullet\left(\mathrm{l}_{1 \mathrm{a}} \bullet \mathrm{~S}+\mathrm{l}_{0 \mathrm{a}} \bullet \overline{\mathrm{~S}}\right) \\
& \bar{Z}_{\mathrm{b}}=\overline{\mathrm{OE}} \bullet\left(\mathrm{I}_{1 \mathrm{~b}} \bullet S+\mathrm{I}_{\mathrm{Ob}} \bullet \overline{\mathrm{~S}}\right) \\
& \bar{Z}_{c}=\overline{O E} \bullet\left(I_{1 c} \bullet S+I_{o c} \bullet \bar{S}\right) \\
& \bar{Z}_{d}=\overline{O E} \bullet\left(l_{1 d} \bullet S+l_{O d} \bullet \bar{S}\right)
\end{aligned}
$$

When the Output Enable input ( $\overline{\mathrm{OE}}$ ) is HIGH, the outputs are forced to a high impedance state. If the outputs of the TRISTATE devices are tied together, all but one device must be in the high impedance state to avoid high currents that would exceed the maximum ratings. Designers should
ensure that Output Enable signals to TRI-STATE devices whose outputs are tied together are designed so there is no overlap.

## Truth Table

## Logic Diagram

TL/F/9950-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Rating (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
DC Input Diode Current ( $I_{\mathrm{IK}}$ )

$$
\begin{array}{ll}
V_{1}=-0.5 \mathrm{~V} & -20 \mathrm{~mA} \\
V_{1}=V_{C C}+0.5 \mathrm{~V} & +20 \mathrm{~mA}
\end{array}
$$

DC Input Voltage ( $\mathrm{V}_{\mathrm{I}}$ )
DC Output Diode Current (lok)
$\mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V}$
$V_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Voltage (Vo)
DC Output Source or Sink Current (lo)
DC V CC or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) $\begin{array}{ll}\text { CDIP } & 175^{\circ} \mathrm{C} \\ \text { PDIP } & 140^{\circ} \mathrm{C}\end{array}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

$$

## 54AC/74AC273

## Octal D Flip-FIop

## General Description

The 'AC273 has eight edge-triggered D-type flip-flops with individual D inputs and Q outputs. The common buffered Clock (CP) and Master Reset ( $\overline{\mathrm{MR}}$ ) input load and reset (clear) all flip-flops simultaneously.
The register is fully edge-triggered. The state of each D input, one setup time before the LOW-to-HIGH clock transition, is transferred to the corresponding flip-flop's Q output.
All outputs will be forced LOW independently of Clock or Data inputs by a LOW voltage level on the MR input. The device is useful for applications where the true output only is required and the Clock and Master Reset are common to all storage elements

## Features

- Ideal buffer for MOS microprocessor or memory

■ Eight edge-triggered D flip-flops

- Buffered common clock
- Buffered, asynchronous master reset
- See '377 for clock enable version
- See '373 for transparent latch version
- See '374 for TRI-STATE version
- Outputs source/sink 24 mA
- Standard Military Drawing (SMD)
— 'AC273: 5962-87756

Ordering Code: See Section 8

## Logic Symbols

## Connection Diagrams

Pin Assignment for DIP, Flatpak and SOIC

TL/F/9954-3

| Pin Names | Description |
| :--- | :--- |

H = HIGH Voltage Level
L = LOW Voltage Level
$X=$ Immaterial
$\mathcal{L}=$ LOW-to-HIGH Transition

## Logic Diagram

Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Rating (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)

$$
-0.5 \mathrm{~V} \text { to }+7.0 \mathrm{~V}
$$

DC Input Diode Current ( $l_{\mathrm{IK}}$ )

$$
\begin{array}{ll}
V_{1}=-0.5 V & -20 \mathrm{~mA} \\
V_{1}=V_{C C}+0.5 V & +20 \mathrm{~mA}
\end{array}
$$

DC Input Voltage ( $\mathrm{V}_{1}$ )
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Diode Current (lok)
$V_{0}=-0.5 \mathrm{~V}$
$V_{O}=V_{C C}+0.5 V$
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
DC Output Voltage (Vo)
DC Output Source or Sink Current (lo)
DC V ${ }_{C C}$ or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
CDIP
$175^{\circ} \mathrm{C}$
$140^{\circ} \mathrm{C}$

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions

| Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) |  |
| :---: | :---: |
| 'AC | 2.0 V to 6.0 V |
| 'ACT | 4.5 to 5.5 V |
| Input Voltage ( $\mathrm{V}_{1}$ ) | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ ) | OV to $\mathrm{V}_{\mathrm{CC}}$ |
| Operating Temperature ( $\mathrm{T}_{\mathrm{A}}$ ) |  |
| 74AC/ACT | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| 54AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) |  |
| 'AC Devices |  |
| $\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\text {CC }}$ |  |
| $\mathrm{V}_{\mathrm{CC}}$ @ 3.3V, $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$ | $125 \mathrm{mV} / \mathrm{ns}$ |
| Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) |  |
| 'ACT Devices |  |
| $\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V |  |
| $\mathrm{V}_{\mathrm{CC}}$ @ 4.5V, 5.5 V | $125 \mathrm{mV} / \mathrm{ns}$ |

## 54AC/74AC280 <br> 9-Bit Parity Generator/Checker

## General Description

The 'AC280 is a high-speed parity generator/checker that accepts nine bits of input data and detects whether an even or an odd number of these inputs is HIGH. If an even number of inputs is HIGH, the Sum Even output is HIGH. If an odd number is HIGH, the Sum Even output is LOW. The Sum Odd output is the complement of the Sum Even output.

## Features

- 9-bit width for memory applications

Ordering Code: See Section 8

## Logic Symbols

| Pin Names | Description |
| :--- | :--- |
| $I_{0}-I_{8}$ | Data Inputs |
| $\Sigma_{O}$ | Odd Parity Output |
| $\Sigma_{E}$ | Even Parity Output |

## Connection Diagrams

| $1,3,5,7,9$ | L | H |

$H=$ HIGH Voltage Level
$L=$ LOW Voltage Level

## Logic Diagram

TL/F/9955-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Rating (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )

$$
-0.5 \mathrm{~V} \text { to }+7.0 \mathrm{~V}
$$

DC Input Diode Current (I $I_{K}$ )

$$
\begin{aligned}
& V_{1}=-0.5 \mathrm{~V} \\
& V_{1}=V_{C C}+0.5 \mathrm{~V}
\end{aligned}
$$

DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
DC Output Diode Current (IOK)

$$
\begin{aligned}
& V_{\mathrm{O}}=-0.5 \mathrm{~V} \\
& \mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
\end{aligned}
$$

DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current (lo)
DC $\mathrm{V}_{\mathrm{CC}}$ or Ground Current per Output Pin (ICC or IGND)
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$\pm 50 \mathrm{~mA}$
$\pm 50 \mathrm{~mA}$
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
CDIP
$175^{\circ} \mathrm{C}$
PDIP $140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions

## 54AC/74AC299 • 54ACT/74ACT299 <br> 8-Input Universal Shift/Storage Register with Common Parallel I/O Pins

## General Description

The 'AC/'ACT299 is an 8-bit universal shift/storage register with TRI-STATE ${ }^{\circledR}$ outputs. Four modes of operation are possible: hold (store), shift left, shift right and load data. The parallel load inputs and flip-flop outputs are multiplexed to reduce the total number of package pins. Additional outputs are provided for flip-flops $Q_{0}, Q_{7}$ to allow easy serial cascading. A separate active LOW Master Reset is used to reset the register.

## Features

- Common parallel I/O for reduced pin count
- Additional serial inputs and outputs for expansion

■ Four operating modes: shift left, shift right, load and store

- TRI-STATE outputs for bus-oriented applications
- Outputs source/sink 24 mA
- 'ACT299 has TTL-compatible inputs
- Standard Military Drawing (SMD)
- 'AC299: 5962-88754
— 'ACT299: 5962-88771

Ordering Code: See Section 8
Logic Symbols

|  | TRI-STATE Output Enable Inputs |
| $\mathrm{Q}_{0}, Q_{7}$ | Parallel Data Inputs or |
|  | TRI-STATE Parallel Outputs |
|  | Serial Outputs |

## Functional Description

The 'AC/'ACT299 contains eight edge-triggered D-type flipflops and the interstage logic necessary to perform synchronous shift left, shift right, parallel load and hold operations. The type of operation is determined by $\mathrm{S}_{0}$ and $\mathrm{S}_{1}$, as shown in the Truth Table. All flip-flop outputs are brought out through TRI-STATE buffers to separate I/O pins that also serve as data inputs in the parallel load mode. $Q_{0}$ and $Q_{7}$ are also brought out on other pins for expansion in serial shifting of longer words.
A LOW signal on $\overline{M R}$ overrides the Select and CP inputs and resets the flip-flops. All other state changes are initiated by the rising edge of the clock. Inputs can change when the clock is in either state provided only that the recommended setup and hold times, relative to the rising edge of CP , are observed.
A HIGH signal on either $\overline{\mathrm{OE}}_{1}$ or $\overline{\mathrm{OE}}_{2}$ disables the TRISTATE buffers and puts the I/O pins in the high impedance state. In this condition the shift, hold, load and reset operations can still occur. The TRI-STATE buffers are also disabled by HIGH signals on both $S_{0}$ and $S_{1}$ in preparation for a parallel load operation.

## Truth Table

| Inputs |  |  |  | Response |
| :---: | :---: | :---: | :---: | :---: |
| $\overline{\text { MR }}$ | $\mathrm{S}_{1}$ | $\mathrm{S}_{0}$ | CP |  |
| L | X | X | X | Asynchronous Reset; $Q_{0}-Q_{7}=L O W$ |
| H | H | H | $\Omega$ | Parallel Load; I/ $\mathrm{O}_{\mathrm{n}} \rightarrow \mathrm{Q}_{\mathrm{n}}$ |
| H | L | H | $\checkmark$ | Shift Right; $\mathrm{DS}_{0} \rightarrow \mathrm{Q}_{0}$, $Q_{0} \rightarrow Q_{1}$, etc. |
| H | H | L | $\checkmark$ | Shift Left, $\mathrm{DS}_{7} \rightarrow \mathrm{Q}_{7}$, $Q_{7} \rightarrow Q_{6}$, etc. |
| H | L | L | X | Hold |

$\mathrm{H}=\mathrm{HIGH}$ Voltage Level
L = LOW Voltage Level

$\mathcal{\sim}=$ LOW-to-HIGH Transition

## Logic Diagram

TL/F/9893-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
DC Input Diode Current (lik)

$$
\begin{aligned}
& V_{1}=-0.5 \mathrm{~V} \\
& V_{1}=V_{C C}+0.5 \mathrm{~V}
\end{aligned}
$$

DC Input Voltage ( $\mathrm{V}_{1}$ )
DC Output Diode Current (lok)
$V_{\mathrm{O}}=-0.5 \mathrm{~V}$
$V_{O}=V_{C C}+0.5 \mathrm{~V}$
DC Output Voltage (Vo)
DC Output Source or Sink Current (lo)
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$

DC VCC or Ground Current
Per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
CDIP
$175^{\circ} \mathrm{C}$
PDIP
$140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. Obviously the databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating

 Conditions| Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) |  |
| :---: | :---: |
| (Unless Otherwise Specified) |  |
| 'AC | 2.0 V to 6.0 V |
| 'ACT | 4.5 V to 5.0 V |

## 54ACT/74ACT323 <br> 8-Bit Universal Shift/Storage Register with Synchronous Reset and Common I/O Pins

## General Description

The 'ACT323 is an 8-bit universal shift/storage register with TRI-STATE ${ }^{\circledR}$ outputs. Parallel load inputs and flip-flop outputs are multiplexed to minimize pin count. Separate serial inputs and outputs are provided for $Q_{0}$ and $Q_{7}$ to allow easy cascading. Four operation modes are possible: hold (store), shift left, shift right and parallel load.

## Features

- Common parallel I/O for reduced pin count
- Additional serial inputs and outputs for expansion
- Four operating modes: shift left, shift right, load and store
- TRI-STATE outputs for bus-oriented applications
- Outputs source/sink 24 mA
- TTL-compatible inputs

Ordering Code: See Section 8

## Functional Description

The 'ACT323 contains eight edge-triggered D-type flip-flops and the interstage logic necessary to perform synchronous reset, shift left, shift right, parallel load and hold operations. The type of operation is determined by $\mathrm{S}_{0}$ and $\mathrm{S}_{1}$ as shown in the Mode Select Table. All flip-flop outputs are brought out through TRI-STATE buffers to separate I/O pins that also serve as data inputs in the parallel load mode. $Q_{0}$ and $Q_{7}$ are also brought out on other pins for expansion in serial shifting of longer words.
A LOW signal on $\overline{\mathrm{SR}}$ overrides the Select inputs and allows the flip-flops to be reset by the next rising edge of CP.

Mode Select Table

| Inputs |  |  |  | Response |
| :---: | :---: | :---: | :---: | :---: |
| $\overline{\mathbf{S R}}$ | $\mathrm{S}_{1}$ | $\mathrm{S}_{0}$ |  |  |
| L | X | X | $\sim$ | Synchronous Reset; $Q_{0}-Q_{7}=$ LOW |
| H | H | H | $\sim$ | Parallel Load; $\mathrm{I} / \mathrm{O}_{\mathrm{n}} \rightarrow \mathrm{Q}_{\mathrm{n}}$ |
| H | L | H | $\checkmark$ | Shift Right; $\mathrm{DS}_{0} \rightarrow \mathrm{Q}_{0}, \mathrm{Q}_{0} \rightarrow \mathrm{Q}_{1}$, etc. |
| H | H | L | $\checkmark$ | Shift Left; $D^{\text {d }} \rightarrow \mathrm{Q}_{7}, \mathrm{Q}_{7} \rightarrow \mathrm{Q}_{6}$, etc. |
| H | L | L | X | Hold |

$H=$ HIGH Voltage Level
L = LOW Voltage Level
$X=$ Immaterial
$\Gamma=$ LOW-to-HIGH Clock Transition

All other state changes are also initiated by the LOW-toHIGH CP transition. Inputs can change when the clock is in either state provided only that the recommended setup and hold times, relative to the rising edge of CP , are observed. A HIGH signal on either $\overline{\mathrm{OE}}_{1}$ or $\overline{\mathrm{OE}}_{2}$ disables the TRI-STATE buffers and puts the I/O pins in the high impedance state. In this condition the shift, load, hold and reset operations can still occur. The TRI-STATE buffers are also disabled by HIGH signals on both $\mathrm{S}_{0}$ and $\mathrm{S}_{1}$ in preparation for a parallel load operation.

TL/F/9787-4
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
DC Input Diode Current ( $I_{K}$ )
$V_{1}=-0.5 \mathrm{~V}$
$V_{1}=V_{C C}+0.5 V$
DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
DC Output Diode Current (IOK)
$\mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V}$
$\mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$

> -0.5 V to +7.0 V  -20 mA +20 mA

DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current ( $l_{0}$ )
DC V $V_{C C}$ or Ground Current Per Output Pin (ICC or IGND)
Storage Temperature (TSTG) Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
$175^{\circ} \mathrm{C}$ PDIP
$140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## 54ACT/74ACT367 <br> Hex Buffer with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACT367 contains six independent non-inverting buffers with TRI-STATE outputs.

## Features

- Outputs source/sink 24 mA

国 'ACT has TTL-compatible inputs

Ordering Code: See Section 8

## Logic Symbol

Function Table

| Inputs |  | Outputs |
| :---: | :---: | :---: |
| $\overline{O E}$ | I | O |
| L | L | H |
| L | $H$ | L |
| H | X | Z |

## 54AC/74AC373 • 54ACT/74ACT373 Octal Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'AC/'ACT373 consists of eight latches with TRI-STATE outputs for bus organized system applications. The flip-flops appear transparent to the data when Latch Enable (LE) is HIGH. When LE is LOW, the data that meets the setup time is latched. Data appears on the bus when the Output Enable ( $\overline{O E}$ ) is LOW. When $\overline{O E}$ is HIGH, the bus output is in the high impedance state.

## Features

- Eight latches in a single package
m TRI-STATE outputs for bus interfacing
a Outputs source/sink 24 mA
- 'ACT373 has TTL-compatible inputs
- Standard Military Drawing (SMD)
- 'AC373: 5962-87555
— 'АСТЗ73: 5962-87556

Ordering Code: See Section 8

## Logic Symbols

| Pin Names | Description |
| :--- | :--- |
| $\mathrm{D}_{0}-\mathrm{D}_{7}$ | Data Inputs |
| LE | Latch Enable Input |
| $\overline{\mathrm{OE}}$ | Output Enable Input |
| $\mathrm{O}_{0}-\mathrm{O}_{7}$ | TRI-STATE Latch Outputs |

## Connection Diagrams

Pin Assignment for LCC

TL/F/9958-4

## Functional Description

The 'AC/'ACT373 contains eight D-type latches with TRISTATE standard outputs. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent, i.e., a latch output will change state each time its D input changes. When LE is LOW, the latches store the information that was present on the D inputs a setup time preceding the HIGH-to-LOW transition of LE. The TRI-STATE standard outputs are controlled by the Output Enable ( $\overline{\mathrm{OE}}$ ) input. When $\overline{O E}$ is LOW, the standard outputs are in the 2-state mode. When $\overline{O E}$ is HIGH, the standard outputs are in the high impedance mode but this does not interfere with entering new data into the latches.

## Truth Table

| Inputs |  |  | Outputs |
| :---: | :---: | :---: | :---: |
| LE | $\overline{\mathbf{O E}}$ | $\mathbf{D}_{\mathbf{n}}$ | $\mathbf{O}_{\mathbf{n}}$ |
| X | $H$ | X | Z |
| H | L | L | L |
| $H$ | L | H | H |
| L | L | X | $\mathrm{O}_{\mathbf{0}}$ |

$H=$ HIGH Voltage Level
L = LOW Voltage Level
$Z=$ High Impedance
$\mathrm{X}=$ Immaterial
$\mathrm{O}_{0}=$ Previous $\mathrm{O}_{0}$ before HIGH to Low transition of Latch Enable

## Logic Diagram

TL/F/9958-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Rating (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Logic Symbols

Connection Diagrams

TL/F/9959-3

TL/F/9959-4

| Pin Names | Description |
| :--- | :--- |
| $D_{0}-D_{7}$ | Data Inputs |
| $\overline{C P}$ | Clock Pulse Input |
| $\overline{O E}$ | TRI-STATE Output Enable Input |
| $\mathrm{O}_{0}-\mathrm{O}_{7}$ | TRI-STATE Outputs |

Functional Description
The 'AC/'ACT374 consists of eight edge-triggered flip-flops with individual D-type inputs and TRI-STATE true outputs. The buffered clock and buffered Output Enable are common to all flip-flops. The eight flip-flops will store the state of their individual $D$ inputs that meet the setup and hold time requirements on the LOW-to-HIGH Clock (CP) transition. With the Output Enable ( $\overline{\mathrm{OE}})$ LOW, the contents of the eight flip-flops are available at the outputs. When the $\overline{\mathrm{OE}}$ is HIGH, the outputs go to the high impedance state. Operation of the $\overline{O E}$ input does not affect the state of the flip-flops.

## Truth Table

| Inputs |  |  | Outputs |
| :---: | :---: | :---: | :---: |
| $D_{n}$ | $C P$ | $\overline{O E}$ | $O_{n}$ |
| $H$ | - | $L$ | $H$ |
| $L$ | - | $L$ | $L$ |
| $X$ | $X$ | $H$ | $Z$ |

H = HIGH Voltage Level
L = LOW Voltage Level
$X=$ Immaterial
$Z=$ High Impedance
$\Omega=$ LOW-to-HIGH Transition

## Logic Diagram

TL/F/9959-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

## Absolute Maximum Rating (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
-0.5 V to +7.0 V
DC Input Diode Current (IK)

$$
\begin{aligned}
& V_{1}=-0.5 V \\
& V_{1}=V_{C C}+0.5 V
\end{aligned}
$$

$$
\begin{aligned}
& -20 \mathrm{~mA} \\
& +20 \mathrm{~mA}
\end{aligned}
$$

DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )

$$
-0.5 \mathrm{~V} \text { to } \mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
$$

DC Output Diode Current (IOK)

$$
\begin{aligned}
& V_{\mathrm{O}}=-0.5 \mathrm{~V} \\
& \mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
\end{aligned}
$$

DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current ( l )
DC V $\mathrm{VC}_{\text {or }}$ or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
$175^{\circ} \mathrm{C}$
$140^{\circ} \mathrm{C}$

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions

| Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) |  |
| :---: | :---: |
| 'AC | 2.0 V to 6.0 V |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage ( $\mathrm{V}_{1}$ ) | OV to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ ) | OV to $\mathrm{V}_{\mathrm{CC}}$ |
| Operating Temperature ( $\mathrm{T}_{\mathrm{A}}$ ) |  |
| 74AC/ACT | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| 54AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) |  |
| 'AC Devices |  |
| $\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\text {CC }}$ |  |
| $\mathrm{V}_{\mathrm{CC}}$ @ 3.3V, $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$ | $125 \mathrm{mV} / \mathrm{ns}$ |
| Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) |  |
| 'ACT Devices |  |
| $\mathrm{V}_{\mathrm{IN}}$ from 0.8 V to 2.0 V |  |
| $\mathrm{V}_{\mathrm{CC}}$ @ 4.5V, 5.5 V | $125 \mathrm{mV} / \mathrm{ns}$ |

## 54AC/74AC377 • 54ACT/74ACT377 Octal D Flip-Flop with Clock Enable

## General Description

The 'AC/'ACT377 has eight edge-triggered, D-type flip-flops with individual $D$ inputs and $Q$ outputs. The common buffered Clock (CP) input loads all flip-flops simultaneously, when the Clock Enable ( $\overline{\mathrm{CE}}$ ) is LOW.
The register is fully edge-triggered. The state of each D input, one setup time before the LOW-to-HIGH clock transition, is transferred to the corresponding flip-flop's Q output. The $\overline{\mathrm{CE}}$ input must be stable only one setup time prior to the LOW-to-HIGH clock transition for predictable operation.

## Features

团 Ideal for addressable register applications

- Clock enable for address and data synchronization applications
[ Eight edge-triggered D flip-flops
a Buffered common clock
■ Outputs source/sink 24 mA
■ See '273 for master reset version
(0) See '373 for transparent latch version
- See '374 for TRI-STATE ${ }^{\circledR}$ version
- 'ACT377 has TTL-compatible inputs
- Standard Military Drawing (SMD)
- 'AC377: 5962-88702
- 'АСТЗ77: 5962-87697

Ordering Code: See Section 8

$\mathcal{\sim}=$ LOW-to-HIGH Clock Transition

## Logic Diagram

Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Rating (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

## Supply Voltage (VCC)

-0.5 V to +7.0 V
DC Input Diode Current ( $I_{\mathrm{I}}$ )

$$
\begin{aligned}
& V_{1}=-0.5 \mathrm{~V} \\
& V_{1}=V_{C C}+0.5 \mathrm{~V}
\end{aligned}
$$

$$
-20 \mathrm{~mA}
$$

$$
+20 \mathrm{~mA}
$$

DC Input Voltage ( $\mathrm{V}_{\mathrm{I}}$ )

$$
-0.5 \mathrm{~V} \text { to } \mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
$$

DC Output Diode Current (IOK)

$$
\begin{array}{lr}
V_{\mathrm{O}}=-0.5 \mathrm{~V} & -20 \mathrm{~mA} \\
\mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V} & +20 \mathrm{~mA} \\
\text { DC Output Voltage }\left(\mathrm{V}_{\mathrm{O}}\right) & -0.5 \mathrm{~V} \text { to to } \mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V} \\
\text { DC Output Source } & \\
\text { or Sink Current (lo) } & \pm 50 \mathrm{~mA} \\
\text { DC } \mathrm{V}_{\mathrm{CC}} \text { or Ground Current } & \\
\text { per Output Pin (ICC or } \left.\mathrm{I}_{\mathrm{GND}}\right) & \pm 50 \mathrm{~mA} \\
\text { Storage Temperature (TSTG) } & -65^{\circ} \mathrm{C} \text { to }+150^{\circ} \mathrm{C} \\
\text { Junction Temperature ( } \left.\mathrm{T}_{\mathrm{J}}\right) & \\
\text { CDIP } & 175^{\circ} \mathrm{C} \\
\text { PDIP } & 140^{\circ} \mathrm{C}
\end{array}
$$

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions

| Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) |  |
| :---: | :---: |
| 'AC | 2.0V to 6.0 V |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage ( $\mathrm{V}_{1}$ ) | OV to $\mathrm{V}_{\mathrm{Cc}}$ |
| Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ ) | OV to $\mathrm{V}_{\mathrm{CC}}$ |
| Operating Temperature ( $\mathrm{T}_{\mathrm{A}}$ ) |  |
| 74AC/ACT | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| 54AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) |  |
| 'AC Devices |  |
| $\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\text {CC }}$ |  |
| $\mathrm{V}_{\text {CC }}$ @ 3.3V, $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$ | $125 \mathrm{mV} / \mathrm{ns}$ |
| Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) |  |
| 'ACT Devices |  |
| $\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V |  |
| $\mathrm{V}_{\mathrm{CC}}$ @ 4.5V, 5.5 V | $125 \mathrm{mV} / \mathrm{ns}$ |

Note 2: See individual datasheets for those devices which differ from the typical input rise and fall times noted here.

## DC Characteristics for 'AC Family Devices

## 54AC/74AC378 Parallel D Register with Enable

## General Description

The 'AC378 is a 6-bit register with a buffered common Enable. This device is similar to the 'AC174, but with common Enable rather than common Master Reset.

## Features

- 6-bit high-speed parallel register
- Positive edge-triggered D-type inputs
- Fully buffered common clock and enable inputs - Input clamp diodes limit high-speed termination effects

Ordering Code: See Section 8

Logic Symbols

| Pin Names | Description |
| :--- | :--- |
| $\bar{E}$ | Enable Input (Active LOW) |
| $D_{0}-D_{5}$ | Data Inputs |
| $C P$ | Clock Pulse Input (Active Rising Edge) |
| $Q_{0}-Q_{5}$ | Outputs |

## Functional Description

The 'AC378 consists of six edge-triggered D-type flip-flops with individual D inputs and Q inputs. The Clock (CP) and Enable ( $\overline{\mathrm{E}}$ ) inputs are common to all flip-flops.
When the $\bar{E}$ input is LOW, new data is entered into the register on the LOW-to-HIGH transition of the CP input. When the $\overline{\mathrm{E}}$ input is HIGH the register will retain the present data independent of the CP input.

## Truth Table

## 54ACT/74ACT399 <br> Quad 2-Port Register

## General Description

The 'ACT399 is the logical equivalent of a quad 2 -input multiplexer feeding into four edge-triggered flip-flops. A common Select input determines which of the two 4-bit words is accepted. The selected data enters the flip-flop on the rising edge of the clock.

## Features

- Select inputs from two data sources
- Fully positive edge-triggered operation
- Outputs source/sink 24 mA
- 'АСТ399 has TTL-compatible inputs

## Ordering Code: See Section 8

## Logic Symbols

Connection Diagrams

| $\mathrm{I}_{1 \mathrm{a}}-\mathrm{I}_{1 \mathrm{~d}}$ | Data Inputs from Source 1 |
| $\mathrm{Q}_{\mathrm{a}}-\mathrm{Q}_{\mathrm{d}}$ | Register True Outputs |

## Functional Description

The 'ACT399 is a high-speed quad 2-port register. It selects four bits of data from either of two sources (Ports) under control of a common Select input (S). The selected data is transferred to a 4-bit output register synchronous with the LOW-to-HIGH transition of the Clock input (CP). The 4 -bit D-type output register is fully edge-triggered. The Data inputs ( $l_{0 x}, l_{1 \mathrm{x}}$ ) and Select input ( S ) must be stable only a setup time prior to and hold time after the LOW-to-HIGH transition of the Clock input for predictable operation.

## 54AC/74AC520 • 54ACT/74ACT520 8-Bit Identity Comparator

## General Description

The 'AC/'ACT520 are expandable 8-bit comparators. They compare two words of up to eight bits each and provide a LOW output when the two words match bit for bit. The expansion input $\bar{I}_{A}=\mathrm{B}$ also serves as an active LOW enable input.

## Features

- Compares two 8-bit words in 6.5 ns typ
- Expandable to any word length
( $\mathbf{4}$ 2-pin package
- Outputs source/sink 24 mA
- 'ACT520 has TTL-compatible inputs

Ordering Code: See Section 8

## Logic Symbols

## Logic Diagram

TL/F/10194-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Rating (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )
-0.5 V to +7.0 V
DC Input Diode Current ( $\mathrm{I}_{\mathrm{K}}$ )

$$
\begin{aligned}
& V_{1}=-0.5 V \\
& V_{1}=V_{C C}+0.5 V
\end{aligned}
$$

$$
-20 \mathrm{~mA}
$$

$$
+20 \mathrm{~mA}
$$

DC Input Voltage ( $V_{1}$ )
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Diode Current (IOK)
$V_{0}=-0.5 \mathrm{~V}$
$V_{O}=V_{C C}+0.5 \mathrm{~V}$
DC Output Voltago (VO)
DC Output Source or Sink Current (lo)
DC V $C C$ or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
PDIP $140^{\circ} \mathrm{C}$

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without excoption, to onsure that the system design is reliable over its power supply, tomporaturo, and output/input loading variables. National does not recommond oporation of FACTTM circuits outside databook specifications.

## Recommended Operating

 Conditions| Supply Voltage $\left(V_{C C}\right)$ | 2.0 V to 6.0 V |
| :--- | ---: |
| 'AC | 4.5 V to 5.5 V |
| 'ACT | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Input Voltage $\left(\mathrm{V}_{1}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage $\left(\mathrm{V}_{\mathrm{O}}\right)$ |  |
| Operating Temperature $\left(T_{A}\right)$ | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| 74AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta t$ )
'AC Devices
$V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{C C}$
$V_{C C}{ }^{\text {© }} 3.3 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V} \quad 125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'ACT Devices
$V_{\mathbb{N}}$ from 0.8 V to 2.0 V
$V_{C C}$ @ 4.5V,5.5V $125 \mathrm{mV} / \mathrm{ns}$

## Applications

TL/F/10194-6

## 54AC/74AC521• 54ACT/74ACT521 <br> 8-Bit Identity Comparator

## General Description

The 'AC/'ACT521 is an expandable 8 -bit comparator. It compares two words of up to eight bits each and provides a LOW output when the two words match bit for bit. The expansion input $\overline{\mathrm{I}}_{\mathrm{A}}=\mathrm{B}$ also serves as an active LOW enable input.

## Features

(1) Compares two 8-bit words in 6.5 ns typ
(1) Expandable to any word length
m 20-pin package
Outputs source/sink 24 mA

- 'ACT521 has TTL-compatible inputs

## Ordering Code: See Section 8

## Logic Symbols

Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )

| CDIP | $175^{\circ} \mathrm{C}$ |
| :--- | :--- |
| PDIP | $140^{\circ} \mathrm{C}$ |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )

| 'AC | 2.0 V to 6.0 V |
| :--- | ---: |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage $\left(\mathrm{V}_{1}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |

## 54ACT/74ACT534 Octal D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACT534 is a high-speed, low-power octal D-type flipflop featuring separate D-type inputs for each flip-flop and TRI-STATE outputs for bus-oriented applications. A buffered Clock (CP) and Output Enable ( $\overline{\mathrm{OE}}$ ) are common to all flip-flops. The 'ACT534 is the same as the 'ACT374 except that the outputs are inverted.

## Features

■ Edge-triggered D-type inputs

- Buffered positive edge-triggered clock

■ TRI-STATE outputs for bus-oriented applications

- Outputs source/sink 24 mA
- 'ACT534 has TTL-compatible inputs
- Inverted output version of 'АСТЗ74

Ordering Code: See Section 8

Pin Assignment

TL/F/9965-4

## Functional Description

The 'ACT534 consists of eight edge-triggered flip-flops with individual D-type inputs and TRI-STATE complementary outputs. The buffered clock and buffered Output Enable are common to all flip-flops. The eight flip-flops will store the state of their individual $D$ inputs that meet the setup and hold times requirements on the LOW-to-HIGH Clock (CP)
transition. With the Output Enable ( $\overline{\mathrm{OE}}$ ) LOW, the contents of the eight flip-flops are available at the outputs. When the $\overline{O E}$ is HIGH, the outputs go to the high impedance state. Operation of the $\overline{O E}$ input does not affect the state of the flip-flops.

## Logic Diagram

## 54AC/74AC540

Octal Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'AC540 is an octal buffer/line drivers designed to be employed as memory and address drivers, clock drivers and bus oriented transmitter/receivers.
These devices are similar in function to the 'AC240 while providing flow-through architecture (inputs on opposite side from outputs). This pinout arrangement makes these devices especially useful as output ports for microprocessors, allowing ease of layout and greater PC board density.

## Features

- TRI-STATE inverting outputs
- Inputs and outputs opposite side of package, allowing easier interface to microprocessors
■ Output source/sink 24 mA

Ordering Code: See Section 8

## Logic Symbol

## 54AC/74AC541 <br> Octal Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'AC541 is an octal buffer/line driver designed to be employed as memory and address drivers, clock drivers and bus oriented transmitter/receivers. The 'AC541 is a noninverting option of the 'AC540.
This device is similar in function to the 'AC244 while providing flow-through architecture (inputs on opposite side from outputs). This pinout arrangement makes this device especially useful as an output port for microprocessors, allowing ease of layout and greater PC board density.

## Features

- TRI-STATE outputs
- Inputs and outputs opposite side of package, allowing easier interface to microprocessors
■ Output source/sink 24 mA
- 'AC540 provides inverted outputs
- Standard Military Drawing (SMD)
— 'AC541: 5962-88706

Ordering Code: See Section 8
Logic Symbol

[^64]
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating Conditions

Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) 'AC

## 54ACT/74ACT563

## Octal Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACT563 is a high-speed octal latch with buffered common Latch Enable (LE) and buffered common Output Enable ( $\overline{\mathrm{OE}}$ ) inputs.
The 'ACT563 device is functionally identical to the 'ACT573, but with inverted outputs.

## Features

■ Inputs and outputs on opposite sides of package allow easy interface with microprocessors

- Useful as input or output port for microprocessors

■ Functionally identical to 'ACT573 but with inverted outputs

- Outputs source/sink 24 mA
- 'ACT563 has TTL-compatible inputs

Ordering Code: See Section 8

Logic Symbols

IEEE/IEC

Connection Diagrams

TL/F/9970-4

## Functional Description

The 'ACT563 contains eight D-type latches with TRI-STATE complementary outputs. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent, i.e., a latch output will change state each time its $D$ input changes. When LE is LOW the latches store the information that was present on the D inputs a setup time preceding the HIGH-to-LOW transition of LE. The TRI-STATE buffers are controlled by the Output Enable ( $\overline{\mathrm{OE}}$ ) input. When $\overline{\mathrm{OE}}$ is LOW, the buffers are in the bi-state mode. When $\overline{\mathrm{OE}}$ is HIGH the buffers are in the high impedance mode but that does not interfere with entering new data into the latches.

Function Table

| Inputs |  | Internal | Outputs | Function |  |
| :---: | :---: | :---: | :---: | :---: | :--- |
| $\overline{\text { OE }}$ | LE | D | Q |  |  |
| H | X | X | X | Z | High-Z |
| H | H | L | H | Z | High-Z |
| H | H | H | L | Z | High-Z |
| H | L | X | NC | Z | Latched |
| L | H | L | H | H | Transparent |
| L | H | H | L | L | Transparent |
| L | L | X | NC | NC | Latched |

H = HIGH Voltage Level
L = LOW Voltage Level
$X=$ Immaterial
Z = High Impedance
NC = No Change

## 54ACT/74ACT564 Octal D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACT564 is a high-speed, low power octal flip-flop with a buffered common Clock (CP) and a buffered common Output Enable ( $\overline{\mathrm{OE}}$ ). The information presented to the D inputs is stored in the flip-flops on the LOW-to-HIGH Clock (CP) transition.
The 'ACT564 device is functionally identical to the 'ACT574, but with inverted outputs.

## Features

■ Inputs and outputs on opposite sides of package allow easy interface with microprocessors

- Useful as input or output port for microprocessors

■ Functionally identical to 'ACT574 but with inverted outputs

- TRI-STATE outputs for bus-oriented applications

■ Outputs source/sink 24 mA

- 'ACT564 has TTL-compatible inputs

## Ordering Code: See Section 8

## 54ACT/74ACT573

## Octal Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACT573 is a high-speed octal latch with buffered common Latch Enable (LE) and buffered common Output Enable ( $\overline{\mathrm{OE}}$ ) inputs.
The 'ACT573 is functionally identical to the 'ACT373 but has inputs and outputs on opposite sides.

## Features

■ Inputs and outputs on opposite sides of package allowing easy interface with microprocessors

- Useful as input or output port for microprocessors
- Functionally identical to 'ACT373
- TRI-STATE outputs for bus interfacing
- Outputs source/sink 24 mA
- 'ACT573 has TTL-compatible inputs
- Standard Military Drawing (SMD)
— 'ACT573: 5962-87664

## Ordering Code: See Section 8

## Logic Symbols

| Pin Names | Description |
| :--- | :--- |
| $\mathrm{D}_{0}-\mathrm{D}_{7}$ | Data Inputs |
| LE | Latch Enable Input |
| $\overline{\mathrm{OE}}$ | TRI-STATE Output Enable Input |
| $\mathrm{O}_{0}-\mathrm{O}_{7}$ | TRI-STATE Latch Outputs |

## Connection Diagrams

Pin Assignment for DIP, Flatpak and SOIC

TL/F/9973-3

TL/F/9973-4

## Functional Description

The 'ACT573 contains eight D-type latches with TRI-STATE output buffers. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent, i.e., a latch output will change state each time its D input changes. When LE is LOW the latches store the information that was present on the $D$ inputs a setup time preceding the HIGH-to-LOW transition of LE. The TRI-STATE buffers are controlled by the Output Enable ( $\overline{\mathrm{OE}}$ ) input. When $\overline{\mathrm{OE}}$ is LOW, the buffers are enabled. When $\overline{O E}$ is HIGH the buffers are in the high impedance mode but this does not interfere with entering new data into the latches.

Truth Table

| Inputs |  |  | Outputs |
| :---: | :---: | :---: | :---: |
| $\overline{\mathbf{O E}}$ | LE | $\mathbf{D}$ | $\mathbf{O}_{\mathbf{n}}$ |
| L | $H$ | $H$ | $H$ |
| L | $H$ | $L$ | L |
| L | L | X | $\mathrm{O}_{\mathbf{0}}$ |
| $H$ | $X$ | $X$ | $Z$ |

H = HIGH Voltage
L = LOW Voltage
$Z=$ High Impedance
$\mathrm{X}=$ Immaterial
$\mathrm{O}_{0}=$ Previous $\mathrm{O}_{0}$ before HIGH-to-LOW transition of Latch Enable

## Logic Diagram

TL/F/9973-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (VCC)
DC Input Diode Current (IK)

$$
\begin{aligned}

$$

DC Input Voltage ( $\mathrm{V}_{1}$ )
DC Output Diode Current (Iok)
$\mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V}$
$V_{O}=V_{C C}+0.5 V$
DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current (o)
DC V CC or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )

| CDIP | $175^{\circ} \mathrm{C}$ |
| :--- | :--- |
| PDIP | $140^{\circ} \mathrm{C}$ |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## 54AC／74AC574 • 54ACT／74ACT574 Octal D－Type Flip－Flop with TRI－STATE ${ }^{\circledR}$ Outputs

## General Description

The＇AC／＇ACT574 is a high－speed，low power octal flip－flop with a buffered common Clock（CP）and a buffered common Output Enable（ $\overline{\mathrm{OE}}$ ）．The information presented to the D inputs is stored in the flip－flops on the LOW－to－HIGH Clock （CP）transition．
The＇AC／＇ACT574 is functionally identical to the＇AC／ ＇ACT374 except for the pinouts．

## Features

－Inputs and outputs on opposite sides of package allowing easy interface with microprocessors
－Useful as input or output port for microprocessors
■ Functionally identical to＇AC／＇ACT374
－TRI－STATE outputs for bus－oriented applications
■ Outputs source／sink 24 mA
－＇ACT574 has TTL－compatible inputs
－Standard Military Drawing（SMD）
—＇ACT574：5962－89601

Ordering Code：See Section 8

| $\overline{O E}$ | TRI－STATE Output Enable Input |
| $\mathrm{O}_{0}-\mathrm{O}_{7}$ | TRI－STATE Outputs |

## Functional Description

The 'AC/'ACT574 consists of eight edge-triggered flip-flops with individual D-type inputs and TRI-STATE true outputs. The buffered clock and buffered Output Enable are common to all flip-flops. The eight flip-flops will store the state of their individual $D$ inputs that meet the setup and hold time requirements on the LOW-to-HIGH Clock (CP) transition. With the Output Enable ( $\overline{\mathrm{OE}})$ LOW, the contents of the eight flip-flops are available at the outputs. When $\overline{O E}$ is HIGH, the outputs go to the high impedance state. Operation of the $\overline{O E}$ input does not affect the state of the flip-flops.

| Inputs |  |  | Internal | Outputs | Function |

## 54AC／74AC646 • 54ACT／74ACT646 Octal Transceiver／Register with TRI－STATE ${ }^{\circledR}$ Outputs

## General Description

The＇AC／＇ACT646 consist of registered bus transceiver cir－ cuits，with outputs，D－type flip－flops and control circuitry pro－ viding multiplexed transmission of data directly from the in－ put bus or from the internal storage registers．Data on the A or $B$ bus will be loaded into the respective registers on the LOW－to－HIGH transition of the appropriate clock pin（CPAB or CPBA）．The four fundamental data handling functions available are illustrated in Figures 1－4．

## Features

－Independent registers for $A$ and $B$ buses
－Multiplexed real－time and stored data transfers
－TRI－STATE outputs
－ 300 mil slim dual－in－line package
－Outputs source／sink 24 mA
－＇ACT646 has TTL compatible inputs
－Standard Military Drawing（SMD）
－＇AC646：5962－89682

## Ordering Code：See Section 8

Logic Symbols

TL／F／10132－1

## Connection Diagrams

Pin Assignment for DIP，Flatpak and SOIC

TL／F／10132－3

Pin Assignment for LCC and PCC
$A_{5} A_{4} A_{3} N C A_{2} A_{1} A_{0}$四回国图7

TL／F／10132－4

| Pin Names | Description |
| :--- | :--- |
| $A_{0}-A_{7}$ | Data Register A Inputs |
|  | Data Register A Outputs |
| $B_{0}-B_{7}$ | Data Register B Inputs |
|  | Data Register B Outputs |
| CPAB，CPBA | Clock Pulse Inputs |
| SAB，SBA | Transmit／Receive Inputs |
| $\bar{G}$ | Output Enable Input |
| DIR | Direction Control Input |

(
*The data output functions may be enabled or disabled by various signals at the $\bar{G}$ and DIR inputs. Data input functions are always enabled; i.e., data at the bus pins will be stored on every LOW-to-HIGH transition of the appropriate clock inputs.
$H=$ HIGH Voltage Level
$X=$ Immaterial
L = LOW Voltage Level

$$
\mathcal{F}=\text { LOW-to-HIGH Transition }
$$

## Logic Diagram

TL/F/10132-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

## Absolute Maximum Rating (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )
-0.5 V to +7.0 V
DC Input Diode Current ( $l_{\mathrm{IK}}$ )

$$
\begin{aligned}
& V_{1}=-0.5 V \\
& V_{1}=V_{C C}+0.5 V
\end{aligned}
$$

DC Input Voltage ( $\mathrm{V}_{1}$ )
DC Output Diode Current (IOK)
$\mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V}$
$\mathrm{V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Voltage (Vo)
DC Output Source or Sink Current (lo)
DC V ${ }_{C C}$ or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP PDIP
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage (VCC)
'AC
'ACT
2.0 V to 6.0 V
4.5 V to 5.5 V

Input Voltage ( $\mathrm{V}_{\mathrm{I}}$ )
Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
Operating Temperature $\left(T_{A}\right)$ 74AC/ACT
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
54AC/ACT
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'AC Devices
$V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{C C}$
$\mathrm{V}_{\text {CC }}$ @ 3.3V, 4.5V,5.5V $125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$V_{C C}$ @ 4.5V, $5.5 \mathrm{~V} \quad 125 \mathrm{mV} / \mathrm{ns}$

## 54AC/74AC648

Octal Transceiver/Register with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'AC648 consists of registered bus transceiver circuits, with outputs, D-type flip-flops and control circuitry providing multiplexed transmission of data directly from the input bus or from the internal storage registers. Data on the A or B bus will be loaded into the respective registers on the LOW-to-HIGH transition of the appropriate clock pin (CPAB or CPBA). The four fundamental data handling functions available are illustrated in Figures 1 thru 4 (See Page 2).

## Features

- Independent registers for A and B buses
- Multiplexed real-time and stored data transfers
- TRI-STATE outputs
- 300 mil slim dual-in-line package
- Outputs source/sink 24 mA
- Inverted data to output

## Ordering Code: See Section 8

## Logic Symbols

## Connection Diagrams

Pin Assignment for DIP, Flatpak and SOIC

TL/F/10133-4

Function Table

| Inputs |  |  |  |  |  | Data 1/0* |  | Function |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\overline{\mathbf{G}}$ | DIR | CPAB | CPBA | SAB | SBA | $A_{0}-A_{7}$ | $B_{0}-B_{7}$ |  |
| H | X | H or L | H or L | X | X | Input | Input | Isolation |
| H | X | $\bigcirc$ | X | X | X |  |  | Clock $\mathrm{A}_{n}$ Data into A Register |
| H | X | X | $\widetilde{ }$ | X | X |  |  | Clock $\mathrm{B}_{\mathrm{n}}$ Data into B Register |
| L | H | X | X | L | X | Input | Output | $A_{n}$ to $B_{n}$-Real Time (Transparent Mode) |
| L | H | $\widetilde{ }$ | X | L | X |  |  | Clock $A_{n}$ Data into A Register |
| L | H | H or L | X | H | X |  |  | A Register to $\mathrm{B}_{\mathrm{n}}$ (Stored Mode) |
| L | H | $\checkmark$ | X | H | X |  |  | Clock $A_{n}$ Data into A Register and Output to $B_{n}$ |
| L | L | X | X | X | L | Output | Input | $B_{n}$ to $A_{n}$-Real Time (Transparent Mode) |
| L | L | X | $\widetilde{ }$ | X | L |  |  | Clock $B_{n}$ Data into $B$ Register |
| L | L | X | HorL | X | H |  |  | B Register to $\mathrm{A}_{\mathrm{n}}$ (Stored Mode) |
| L | L | X | $\checkmark$ | X | H |  |  | Clock $\mathrm{B}_{\mathrm{n}}$ Data into B Register and Output to $\mathrm{A}_{n}$ |

*The data output functions may be enabled or disabled by various signals at the $\overline{\mathcal{G}}$ and DIR inputs. Data input functions are always enabled; i.e., data at the bus pins will be stored on every LOW-to-HIGH transition of the clock inputs.
$H=$ HIGH Voltage Level
L = LOW Voltage Level
$\mathrm{X}=$ Irrelevant
$\sim=$ LOW-to-HIGH Transition

Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Rating (Note 1)
If Milltary/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (VCC)
DC Input Diode Current (IK)
$V_{1}=-0.5 \mathrm{~V}$
$V_{1}=V_{C C}+0.5 V$
DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
DC Output Diode Current (lok)

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V} \\
& \mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
\end{aligned}
$$

DC Output Voltage (VO)
DC Output Source or Sink Current (lo)
DC V CC or Ground Current per Output Pin (ICC or IGND)
-0.5 V to +7.0 V

Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
$175^{\circ} \mathrm{C}$ PDIP
Note 1: Absolute to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating Conditions

Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )

| 'AC | 2.0 V to 6.0 V |
| :--- | ---: |
| 'ACT | 4.5 V to 5.5 V |
| Input Voltage $\left(\mathrm{V}_{1}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage $\left(\mathrm{V}_{\mathrm{O}}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Operating Temperature $\left(\mathrm{T}_{\mathrm{A}}\right)$ |  |
| 74AC/ACT | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| 54AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'AC Devices $V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{C C}$ $V_{C C}$ @ 3.3V, 4.5V, 5.5V

125 mV/ns
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$\mathrm{V}_{\mathrm{CC}}$ @ $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$

## DC Characteristics for 'AC Family Devices

## 54ACT/74ACT705 Arithmetic Logic Unit for Digital Signal Processing Applications

## General Description

The 'ACT705 is a high-speed arithmetic processing integrated circuit which is packaged in an 84-pin leadless chip carrier. It features separate input buses that provide data and instruction codes to a high-speed single-cycle 16-bit ALU and an 8 -bit by 8 -bit parallel multiplier/accumulator.
The ALU is a 16-bit parallel design which supports sixteen arithmetic and logic functions, as well as carry-in/out and borrow-in/out. The multiplier/accumulator, which offers a full 16-bit product, provides for unsigned, signed, mixed mode and imaginary number multiplication. Product accumulation with sum and difference arithmetic is available in each multiplier operating mode.
The 16-bit results of the ALU and multiplier/accumulator are multiplexed to a single set of TRI-STATE ${ }^{\oplus}$ output buffers. The two ALU and multiplier/accumulator carry-out bits, as well as the 4-bit status field indicating ALU and multiplier/ accumulator error conditions make up the remaining six bits of the entire 22 -bit output.

## Features

- 84-pin, PCC, CPGA
- Outputs source/sink 8 mA
- 'ACT705 has TTL-compatible inputs
- High throughput achieved with high degree of parallelism in the architecture
- Pipelined stages
- High-speed 16 -bit ALU and an $8 \times 8$ complex multiplier
- 16-bit full ALU performs sixteen Boolean and arithmetic functions with carry-in and carry-out
■ $8 \times 8$ parallel multiplier supports unsigned, signed, complex or mixed mode multiplications, produces 16 -bit result with carry-out
- Separate data and instruction buses allow instruction fetches in parallel with execution-single cycle operation
- Accepts 8 - or 16 -bit data and delivers a 16 -bit output
- Data register bank configured to accept a combination of 8 - or 16-bit data
- Separate clocks for ALU instruction, multiplier instruction, data, ALU accumulator and multiplier accumulator registers
- Clustered clock pins for ease of board design
- 16-bit ALU/accumulator with feedback to ALU input
- Status of accumulator inputs is monitored: conditions monitored include twos complement overflow, underflow or equal-to-zero

## Applications

■ Voice-band signal processing

- Discrete Fourier transform applications
— FIR filters
- IIR filters
- Fast Fourier transform applications
- Spectrum analysis
- Speech recognition

## Connection Diagram

## 54ACT/74ACT715•LM1882 Programmable Video Sync Generator

## General Description

The 'ACT715/LM1882 is a 20-pin TTL-input compatible device capable of generating Horizontal, Vertical and Composite Sync and Blank signals for televisions and monitors. All pulse widths are completely definable by the user. The device is capable of generating signals for both interlaced and noninterlaced modes of operation. Equalization and serration pulses can be introduced into the Composite Sync signal when needed.
Four additional signals can also be made available when Composite Sync or Blank are used. These signals can be used to generate horizontal or vertical gating pulses, cursor position or vertical Interrupt signal.
The 'ACT715/LM1882 makes no assumptions concerning the system architecture. Line rate and field/frame rate are all a function of the values programmed into the data registers, the status register, and the input clock frequency.

## Features

■ Maximum Input Clock Frequency > 100 MHz

- Interlaced and non-interlaced formats available
- Separate or composite horizontal and vertical Sync and Blank signals available
■ Complete control of pulse width via register programming
- All inputs are TTL compatible
- 8 mA drive on all outputs
- Default RS170/NTSC values mask programmed into registers
- Orderable as linear device LM1882CN or LM1882CM

## Ordering Code: See Section 8

## Connection Diagrams

TL/F/10137-1

TL/F/10137-2

## Logic Block Diagram

TL/F/10137-3

## Pin Description

There are a Total of 13 inputs and 5 outputs on the 'ACT715/LM1882.

Data Inputs D0-D7: The Data Input pins connect to the Address Register and the Data Input Register.
 device on the falling edge of the LOAD signal. The signal determines if an address ( 0 ) or data (1) is present on the data bus.
L/HBYTE: The L/HBYTE signal is latched into the device on the falling edge of the LOAD signal. The signal determines if data will be read into the 8 LSB's ( 0 ) or the 4 MSB's (1) of the Data Registers. A 1 on this pin when an ADDR/ DATA is a 0 enables Auto-Load Mode.
LOAD: The Load control pin loads data into the Address or Data Registers on the rising edge. $\overline{\text { ADDR/DATA and }}$ L/HBYTE data is loaded into the device on the falling edge of the clock. The Load pin has been implemented as a Schmitt trigger input for better noise immunity.
CLOCK: System Clock input from which all timing is derived. The clock pin has been implemented as a Schmitt trigger for better noise immunity.
CLR: The Clear pin is an asynchronous input that initializes the device when it is high. Initialization consists of setting all registers to their mask programmed values, and initializing all counters, comparators and registers. The clear pin has been implemented as a Schmitt trigger for better noise immunity.
ODD/EVEN: Output that identifies if display is in odd (HIGH) or even (LOW) field of interlace when device is in interlaced mode of operation. In noninterlaced mode of operation this input is always HIGH. Data can be serially scanned out on this pin during test mode.

VCSYNC: Outputs Vertical or Composite Sync signal based on value of the Status Register.
VCBLANK: Outputs Vertical or Composite Blanking signal based on value of the Status Register.
HBLHDR: Outputs Horizontal Blanking signal, Horizontal Gating signal or cursor position based on value of the Status Register.
HSYNVDR: Outputs Horizontal Sync signal, Vertical Gating signal or Vertical Interrupt signal based on value of Status Register.

## Register Description

All of the data registers are 12 bits wide. Width's of all pulses are defined by specifying the start count and end count of all pulses. Horizontal pulses are specified with-respect-to the number of clock pulses per line and vertical pulses are specified with-respect-to the number of lines per frame.

## REG0-STATUS REGISTER

The Status Register controls the mode of operation, the signals that are output and the polarity of these outputs.

Bits 0-2

| $\mathbf{B}_{\mathbf{2}}$ | $\mathbf{B}_{\mathbf{1}}$ | $\mathbf{B}_{\mathbf{0}}$ | VCBLANK | VCSYNC | HBLHDR | HSYNVDR |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | CBLANK | CSYNC | HGATE | VGATE |
| 0 | 0 | 1 | VBLANK | CSYNC | HBLANK | VGATE |
| 0 | 1 | 0 | CBLANK | VSYNC | HGATE | HSYNC |
| 0 | 1 | 1 | VBLANK | VSYNC | HBLANK | HSYNC |
| 1 | 0 | 0 | CBLANK | CSYNC | CURSOR | VINT |
| 1 | 0 | 1 | VBLANK | CSYNC | HBLANK | VINT |
| 1 | 1 | 0 | CBLANK | VSYNC | CURSOR | HSYNC |
| 1 | 1 | 1 | VBLANK | VSYNC | HBLANK | HSYNC |

Register Description (Continued)

| Bits 3-4 |  |  |
| :---: | :---: | :--- |
| $\mathbf{B}_{\mathbf{4}}$ | $\mathbf{B}_{\mathbf{3}}$ | Mode of Operation |
| 0 | 0 | Interlaced Double Serration and <br> Equalization |
| 0 | 1 | Non Interlaced Double Serration |
| 1 | 0 | Illegal State |
| 1 | 1 | Non Interlaced Single Serration <br> and Equalization |

Bits 5-8
Bits 5 through 8 control the polarity of the outputs. A value of zero in these bit locations indicates a pulse active LOW. A value of 1 indicates an active HIGH pulse.
B5- VCBLANK Polarity
B6- VCSYNC Polarity
B7- HBLHDR Polarity
B8- HSYNVDR Polarity
Bits 9-11
Bits 9 through 11 enable several different features of the device.
B9- Enable Equalization/Serration Pulses (0) Disable Equalization/Serration Pulses (1)
B10- Disable System Clock (0) Enable System Clock (1)
B11- Disable Counter Test Mode (0) Enable Counter Test Mode (1)

## HORIZONTAL INTERVAL REGISTERS

The Horizontal Interval Registers determine the number of clock cycles per line and the characteristics of the Horizontal Sync and Blank pulses.
REG1- Horizontal Front Porch
REG2- Horizontal Sync Pulse End Time
REG3- Horizontal Blanking Width
REG4- Horizontal Interval Width \# of Clocks per Line

## VERTICAL INTERVAL REGISTERS

The Vertical Interval Registers determine the number of lines per frame, and the characteristics of the Vertical Blank and Sync Pulses.
REG5- Vertical Front Porch
REG6- Vertical Sync Pulse End Time
REG7- Vertical Blanking Width
REG8- Vertical Interval Width \# of Lines per Frame

## EQUALIZATION AND SERRATION PULSE SPECIFICATION REGISTERS

These registers determine the width of equalization and serration pulses and the vertical interval over which they occur.
REG 9- Equalization Pulse Width End Time
REG10- Serration Pulse Width End Time
REG11- Equalization/Serration Pulse Vertical Interval Start Time
REG12- Equalization/Serration Pulse Vertical Interval End Time

VERTICAL INTERRUPT SPECIFICATION REGISTERS
These Registers determine the width of the Vertical Interrupt signal if used.
REG13- Vertical Interrupt Activate Time
REG14- Vertical Interrupt Deactivate Time

## CURSOR LOCATION REGISTERS

These 4 registers determine the cursor position location, or they generate separate Horizontal and Vertical Gating signals.
REG15- Horizontal Cursor Position Start Time
REG16-Horizontal Cursor Position End Time
REG17- Vertical Cursor Position Start Time
REG18- Vertical Cursor Position End Time

## Signal Specification

## HORIZONTAL SYNC AND BLANK SPECIFICATIONS

All horizontal signals are defined by a start and end time. The start and end times are specified in number of clock cycles per line. The start of the horizontal line is considered pulse 1 not 0 . The horizontal counters start at 1 and count until HMAX. The value of HMAX must be divisible by 2. This limitation is imposed because during interlace operation this value is internally divided by 2 in order to generate serration and equalization pulses at $2 \times$ the horizontal frequency. Horizontal signals will change on the falling edge of the CLOCK signal. Signal specifications are shown below.
Horizontal Period (HPER) $=$ REG $(4) \times$ ckper
Horizontal Blanking Width $=[\operatorname{REG}(3)-1] \times$ ckper
Horizontal Sync Width $=[$ REG(2) - REG(1) $] \times$ ckper
Horizontal Front Porch $=[R E G(1)-1] \times$ ckper

## VERTICAL SYNC AND BLANK SPECIFICATION

All vertical signals are defined in terms of number of lines per frame. This is true in both interlaced and noninterlaced modes of operation. Care must be taken to not specify the Vertical Registers in terms of lines per field. The vertical counter starts at the value of 1 and counts until the value of VMAX. No restrictions exist on the values placed in the vertical registers. Vertical Blank will change on the leading edge of HBLANK. Vertical Sync will change on the leading edge of HSYNC.
Vertical Frame Period (VPER) $=$ REG $(8) \times$ hper Vertical Field Period (VPER/n) $=$ REG $(8) \times$ hper $/ n$
Vertical Blanking Width $=[$ REG $(7)-1] \times h p e r / n$
Vertical Syncing Width $=[$ REG(6) - REG(5) $] \times$ hper $/ n$
Vertical Front Porch $=[\operatorname{REG}(5)-1] \times h p e r / n$
where $\mathrm{n}=1$ for noninterlaced

$$
\mathrm{n}=2 \text { for interlaced }
$$

## COMPOSITE SYNC AND BLANK SPECIFICATION

Composite Sync and Blank signals are created by logically ANDing (ORing) the active LOW (HIGH) signals of the corresponding vertical and horizontal components of these signals. The Composite Sync signal may also include serration and/or equalization pulses. The serration pulse interval occurs in place of the Vertical Sync interval. Equalization puls-

## Signal Specification (Continued)

es occur preceding and/or following the serration pulses. The width and location of these pulses can be programmed through the registers shown below.
Horizontal Equalization PW $=[$ REG $(9)-$ REG(1) $] \times$ ckper
Horizontal Serration PW $=[\operatorname{REG}(4) / n+$ REG(1) REG(10)] $\times$ ckper
Where $\mathrm{n}=1$ for noninterlaced single serration/equalization
$\mathrm{n}=2$ for noninterlaced double serration/equalization
$\mathrm{n}=2$ for interlaced operation

## HORIZONTAL AND VERTICAL GATING SIGNALS

Horizontal and Vertical Gating Signals are available for use when Composite Sync and Blank signals are selected and the value of bit 2 of the status register is 0 . The Vertical Gating signal will change in the same manner as that specified for the Vertical Blank.
$\begin{aligned} \text { Horizontal Gating Signal Width }= & \underset{\text { ckper }}{[\operatorname{REG}(16)-\text { REG(15) }] \times} \\ \text { Vertical Gating Signal Width } & =\underset{\text { hper }}{[\text { REG(18) }- \text { REG(17) }] \times}\end{aligned}$

## CURSOR POSITION AND VERTICAL INTERRUPT

The Cursor Position and Vertical Interrupt signal are available when Composite Sync and Blank signals are selected and bit 2 of the Status Register is set to the value of 1. The cursor position generates a single pulse of $n$ clocks wide during every line that the cursor is specified. The signals are generated by logically ORing (ANDing) the active LOW (HIGH) signals specified by the registers used for generating Horizontal and Vertical Gating signals. The Vertical Interrupt signal generates a pulse during the vertical interval specified. The Vertical Interrupt signal will change in the same manner as that specified for the Vertical Blanking signal.
Horizontal Cursor Width $=[$ REG(16) - REG(15) $] \times$ ckper
Vertical Cursor Width $=[$ REG(18) - REG(17) $] \times$ hper
Vertical Interrupt Width $=[$ REG(14) - REG(13) $] \times$ hper

## Addressing Logic

The register addressing logic is composed of two blocks of logic. The first is the address register and counter (ADDRCNTR), and the second is the address decode (ADDRDEC).

## ADDRCNTR LOGIC

Addresses for the data registers can be generated by one of two methods. Manual addressing requires that each byte of each register that needs to be loaded needs to be addressed. To load both bytes of all 19 registers would require a total of 57 Load cycles (19 Address and 38 Data cycles). Auto Addressing requires that only the initial register value be specified. The Auto Load sequence would require only 39 Load cycles to completely program all registers (1 Address and 38 Data). In the auto load sequence the low order byte of the data register will be written first followed by the high order byte on the next load cycle. At the time the High

Byte is written the address counter is incremented by 1. The counter has been implemented to loop on the initial value loaded into the address register. For example: If a value of 0 was written into the address register then the counter would count from 0 to 18 before resetting back to 0 . If a value of 15 was written into the address register then the counter would count from 15 to 18 before looping back to 15 . If a value greater than or equal to 18 is placed into the address register the counter will continuously loop on this value. Auto addressing is initiated on the falling edge of load when ADDRDATA is 0 and LHBYTE is 1 . Incrementing and loading of data registers will not commence until the falling edge of LOAD after ADDRDATA goes to 1 . The next rising edge of LOAD will load the first byte of data. Auto Incrementing is disabled on the falling edge of load after ADDRDATA and LHBYTE goes low.

Auto Addressing Mode

| Cycle \# | Load Falling Edge | Load Rising Edge |
| :---: | :--- | :--- |
| 1 | Enable Auto Addressing | Load Start Address $n$ |
| 2 | Enable Lbyte Data Load | Load Lbyte $(n)$ |
| 3 | Enable Hbyte Data Load | Load Hbyte $(n)$; Inc Counter |
| 4 | Enable Lbyte Data Load | Load Lbyte $(n+1)$ |
| 5 | Enable Hbyte Data Load | Load Hbyte $(n+1)$ Inc Counter |
| 6 | Enable Manual Addressing | Load Address |

## Addressing Logic (Continued)

## ADDRDEC LOGIC

The ADDRDEC logic decodes the current address and generates the enable signal for the appropriate register. The enable values for the registers and counters change on the falling edge of LOAD. Since the data registers are disabled at this time any overlap of enable signals will not cause register data to change. The following Addresses are used by the device.
Address 0 Status Register REGO
Address 1-18 Data Registers REG1-REG18
Address 19-21 Unused
Address 22/54 Restart Vector (Restarts Device)
Address 23/55 Clear Vector (Zeros All Registers)
Address 24-31 Unused
Address 32-50 Register Scan Addresses
Address 51-53 Counter Scan Addresses
Address 56-63 Unused
At any given time only one register at most is selected. It is possible to have no registers selected.

## VECTORED CLEAR ADDRESS

Addresses $23(17 \mathrm{H})$ or $55(37 \mathrm{H})$ is used to clear all registers simultaneously. This function may be desirable to use prior to loading new data into the Data or Status Registers. This address is read into the device in a similar fashion as all of the other registers.

## VECTORED RESTART ADDRESS

The function of addresses $22(16 \mathrm{H})$ or $54(36 \mathrm{H})$ are similar to that of the CLR pin except that the programming of the registers is not affected. It is recommended but not required that this address is read after the initial device configuration load sequence.

## SCAN MODE LOGIC

A scan mode is available in the ACT715/LM1882 that allows the user to non-destructively verify the contents of the registers. Scan mode is invoked through reading a scan address into the address register. The scan address of a given register is defined by the Data register address +32 . The internal Clocking signal is disabled when a scan address is read. Disabling the clock freezes the device in it's present state. Data can then be serially scanned out of the data registers through the ODD/EVEN Pin. The value of the two horizontal counters and 1 vertical counter can also be scanned out by using address numbers 51-53.

Normal device operation can be resumed by latching in a non-scan address. As the scanning of the registers is a nondestructive scan, the device will resume correct operation from the point at which it was halted.

## RS170 Default Register Values

The tables below show the values programmed for the RS170 Format and how they compare against the actual EIA RS170 Specifications. The default signals that will be displayed are CSYNC, CBLANK, HDRIVE and VDRIVE. The device initially starts at the beginning of the odd field of interlace. All signals have active low pulses and the clock is disabled at power up. Registers 13 and 14 are not involved in the actual signal information. If the Vertical Interrupt was selected a pulse indicating the active lines would be displayed.

| Reg | D Value H |  | Register Description |
| :---: | :---: | :---: | :--- |
| REG0 | 0 | 000 | Status Register |
| REG1 | 23 | 017 | HFP End Time |
| REG2 | 91 | $05 B$ | HSYNC Pulse End Time |
| REG3 | 157 | $09 D$ | HBLANK Pulse End Time |
| REG4 | 910 | $38 E$ | Total Horizontal Clocks |
| REG5 | 7 | 007 | VFP End Time |
| REG6 | 13 | $00 D$ | VSYNC Pulse End Time |
| REG7 | 41 | 029 | VBLANK Pulse End Time |
| REG8 | 525 | $20 D$ | Total Vertical Lines |
| REG9 | 57 | 038 | Equalization Pulse End Time |
| REG10 | 410 | $19 A$ | Serration Pulse Start Time |
| REG11 | 1 | 001 | Pulse Interval Start Time |
| REG12 | 19 | 013 | Pulse Interval End Time |
| REG13 | 41 | 029 | Vertical Interrupt Activate Time |
| REG14 | 526 | $20 E$ | Vertical Interrupt Deactivate Time |
| REG15 | 911 | $38 F$ | Horizontal Drive Start Time (1) |
| REG16 | 92 | 05 C | Horizontal Drive End Time |
| REG17 | 1 | 001 | Vertical Drive Start Time |
| REG18 | 21 | 015 | Vertical Drive End Time |

|  | Rate | Period |
| :--- | :--- | :--- |
| Input Clock | 14.31818 MHz | 69.841 ns |
| Line Rate | 15.73426 kHz | $63.556 \mu \mathrm{~S}$ |
| Field Rate | 59.94 Hz | 16.683 ms |
| Frame Rate | 29.97 Hz | 33.367 ms |

| Signal | Width | $\mu \mathbf{s}$ | $\% \mathbf{H}$ | Specification $(\mu \mathbf{s})$ |
| :--- | ---: | :---: | :---: | :---: |
| HFP | 22 Clocks | 1.536 |  | $1.5 \pm 0.1$ |
| HSYNC Width | 68 Clocks | 4.749 | 7.47 | $4.7 \pm 0.1$ |
| HBLANK Width | 156 Clocks | 10.895 | 17.15 | $10.9 \pm 0.2$ |
| HDRIVE Width | 91 Clocks | 6.356 | 10.00 | $0.1 \mathrm{H} \pm 0.005 \mathrm{H}$ |
| HEQP Width | 34 Clocks | 2.375 | 3.74 | $2.3 \pm 0.1$ |
| HSERR Width | 68 Clocks | 4.749 | 7.47 | $4.7 \pm 0.1$ |
| HPER IOD | 910 Clocks | 63.556 | 100 |  |

RS170 Default Register Values (Continued)

| Signal | Width | $\mu \mathbf{s}$ | $\% \mathbf{V}$ | Specification |

| VPERIOD (field) | 262.5 Lines | 16.683 ms |  | $16.683 \mathrm{~ms} /$ Field |
| VPERIOD (frame) | 525 Lines | 33.367 ms |  | $33.367 \mathrm{~ms} /$ Frame |

## Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
-0.5 V to +7.0 V
DC Input Diode Current (IIK)

$$
\begin{aligned}
& V_{1}=-0.5 V \\
& V_{1}=V_{C C}+0.5 V
\end{aligned}
$$

DC Input Voltage ( $\mathrm{V}_{1}$ )
DC Output Diode Current (IOK)

$$
\begin{aligned}
& V_{\mathrm{O}}=-0.5 \mathrm{~V} \\
& \mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
\end{aligned}
$$

DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current (lo)
DC V ${ }_{C C}$ or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG) Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP PDIP
$175^{\circ} \mathrm{C}$
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$\pm 15 \mathrm{~mA}$
$\pm 20 \mathrm{~mA}$
$-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$
$140^{\circ} \mathrm{C}$

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

54ACT/74ACT818 8-Bit Diagnostic Register

## General Description

The 'ACT818 is a high-speed, general-purpose pipeline register with an on-board diagnostic register for performing serial diagnostics and/or writable control store loading.
The D-to-Y path provides an 8-bit parallel data path pipeline register for normal system operation. The diagnostic register can load parallel data to or from the pipeline register and can output data through the D input port (as in WCS loading).
The 8-bit diagnostic register has multiplexer inputs that select parallel inputs from the Y-port or adjacent bits in the diagnostic register to operate as a right-shift-only register. This register can then participate in a serial loop throughout the system where normal data, address, status and control registers are replaced with 'ACT818 diagnostic pipeline registers. The loop can be used to scan in a complete test routine starting point (Data, Address, etc.). Then after a specified number of machine cycles it scans out the results to be inspected for the expected results. WCS loading can be accomplished using the same technique. An instruction word can be serially shifted into the shadow register and written into the WCS RAM by enabling the D output.

## Features

- On-line and off-line system diagnostics

■ Swaps the contents of diagnostic register and output register

- Diagnostic register and diagnostic testing
- Cascadable for wide control words as used in microprogramming
- Edge-triggered D registers
- Outputs source/sink 24 mA
- 'ACT818 has TTL-compatible inputs

■ 'ACT818 is functionally- and pin-compatible to AMD Am29818 and MMI 74S818

## Applications

- Register for microprogram control store
- Status register
- Data register
- Instruction register
- Interrupt mask register
- Pipeline register
- General purpose register
- Parallel-serial/serial-parallel converter

Ordering Code: See Section 8

Logic Symbol

## Diagnostic Register

TL/F/9801-4
Block Diagram

Functional Description
Data transfers into the diagnostic register occur on the LOW-to-HIGH transition of DCLK. Mode and SDI determine what data source will be loaded. The pipeline register is loaded on the LOW-to-HIGH transition of PCLK. Mode selects whether the data source is the data input or the diag-
nostic register output. Because of the independence of the clock inputs, data can be shifted in the diagnostic register via DCLK and loaded into the pipeline register from the data input via PCLK simultaneously, as long as no setup or hold times are violated. This simultaneous operation is legal.

Function Table

| Inputs |  |  |  | Outputs |  |  | Operation |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## 54AC/74AC821•54ACT/74ACT821 10-Bit D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'AC/'ACT821 is a 10 -bit D flip-flop with TRI-STATE outputs arranged in a broadside pinout.
The 'AC/'ACT821 is functionally identical to the AM29821.

## Features

- TRI-STATE outputs for bus interfacing
- Noninverting outputs
- Outputs source/sink 24 mA
- 'ACT821 has TTL-compatible inputs
- Standard Military Drawing (SMD)
— 'ACT821: 5962-88705

Ordering Code: See Section 8

TL/F/10139-3

Pin Assignment for LCC
$D_{7} D_{6} D_{5} N C D_{4} D_{3} D_{2}$

TL/F/10139-4

Functional Description
The 'AC/'ACT821 consists of ten D-type edge-triggered flipflops. The buffered Clock (CP) and buffered Output Enable $(\overline{\mathrm{OE}})$ are common to all flip-flops. The flip-flops will store the state of their individual $D$ inputs that meet the setup and hold time requirements on the LOW-to-HIGH CP transition. With $\overline{O E}$ LOW the contents of the flip-flops are available at
the outputs. When OE is HIGH the outputs go to the high impedance state. Operation of the $\overline{\mathrm{OE}}$ input does not affect the state of the flip-flops.
The 'AC/'ACT821 is functionally and pin compatible with the AM29821.

Function Table

| Inputs |  |  | Internal | Outputs | Function |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\overline{\mathbf{O E}}$ | CP | D | Q | O |  |

## 54ACT/74ACT823

## 9-Bit D Flip-Flop

## General Description

The 'ACT823 is a 9-bit buffered register. It features Clock Enable and Clear which are ideal for parity bus interfacing in high performance microprogramming systems. The 'ACT823 offers noninverting outputs and is fully compatible with AMD's Am29823.

## Features

- Outputs source/sink 24 mA
- TRI-STATE ${ }^{\circledR}$ outputs for bus interfacing
- Inputs and outputs are on opposite sides
- 'ACT823 has TTL-compatible inputs

Ordering Code: See Section 8

## Functional Description

The 'ACT823 consists of nine D-type edge-triggered flipflops. These have TRI-STATE outputs for bus systems organized with inputs and outputs on opposite sides. The buffered clock (CP) and buffered Output Enable ( $\overline{\mathrm{OE}}$ ) are common to all flip-flops. The flip-flops will store the state of their individual D inputs that meet the setup and hold time requirements on the LOW-to-HIGH CP transition. With $\overline{O E}$ LOW, the contents of the flip-flops are available at the outputs. When $\overline{\mathrm{OE}}$ is HIGH, the outputs go to the high impedance state. Operation of the $\overline{O E}$ input does not affect
the state of the flip-flops. In addition to the Clock and Output Enable pins, there are Clear (CLR) and Clock Enable (EN) pins. These devices are ideal for parity bus interfacing in high performance systems.
When $\overline{C L R}$ is LOW and $\overline{O E}$ is LOW, the outputs are LOW. When $\overline{\mathrm{CLR}}$ is HIGH, data can be entered into the flip-flops. When EN is LOW, data on the inputs is transferred to the outputs on the LOW-to-HIGH clock transition. When the EN is HIGH, the outputs do not change state, regardless of the data or clock input transitions.

## 54ACT/74ACT825 <br> 8-Bit D Flip-Flop

## General Description

The 'ACT825 is an 8-bit buffered register. They have Clock Enable and Clear features which are ideal for parity bus interfacing in high performance microprogramming systems. Also included are multiple enables that allow multi-use control of the interface. The 'ACT825 has noninverting outputs and is fully compatible with AMD's Am29825.

## Features

- Outputs source/sink 24 mA
- Inputs and outputs are on opposite sides
- 'ACT825 has TTL-compatible inputs

## Functional Description

The 'ACT825 consists of eight D-type edge-triggered flipflops. These devices have TRI-STATE ${ }^{\circledR}$ outputs for bus systems, organized in a broadside pinning. In addition to the clock and output enable pins, the buffered clock (CP) and buffered Output Enable ( $\overline{\mathrm{OE}}$ ) are common to all flip-flops. The flip-flops will store the state of their individual $D$ inputs that meet the setup and hold time requirements on the LOW-to-HIGH CP transition. With $\overline{\mathrm{OE}}_{1}, \overline{\mathrm{OE}}_{2}$ and $\overline{\mathrm{OE}}_{3}$ LOW, the contents of the flip-flops are available at the outputs. When one of $\overline{O E}_{1}, \overline{O E}_{2}$ or $\overline{O E}_{3}$ is HIGH, the outputs go to the high impedance state.

Operation of the $\overline{O E}$ input does not affect the state of the flip-flops. The 'ACT825 has Clear ( $\overline{\mathrm{CLR} \text { ) and Clock Enable }}$ (EN) pins. These pins are ideal for parity bus interfacing in high performance systems.
When $\overline{C L R}$ is LOW and $\overline{O E}$ is LOW, the outputs are LOW. When CLR is HIGH, data can be entered into the flip-flops. When $\overline{E N}$ is LOW, data on the inputs is transferred to the outputs on the LOW-to-HIGH clock transition. When EN is HIGH, the outputs do not change state, regardless of the data or clock input transitions.

## 54ACT／74ACT841

## 10－Bit Transparent Latch with TRI－STATE ${ }^{\circledR}$ Outputs

## General Description

The＇ACT841 bus interface latch is designed to eliminate the extra packages required to buffer existing latches and provide extra data width for wider address／data paths or buses carrying parity．The＇ACT841 is a 10－bit transparent latch，a 10 －bit version of the＇ACT373．

## Ordering Code：See Section

TL／F／10156－4

## Functional Description

The ACT841 consists of ten D-type latches with TRI-STATE outputs. The flip-flops appear transparent to the data when Latch Enable (LE) is HIGH. This allows asynchronous operation, as the output transition follows the data in transition.

On the LE HIGH-to-LOW transition, the data that meets the setup and hold time is latched. Data appears on the bus when the Output Enable ( $\overline{\mathrm{OE}}$ ) is LOW. When $\overline{\mathrm{OE}}$ is HIGH the bus output is in the high impedance state.

| Function Table |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :--- | :---: |
| Inputs |  |  | Internal | Output | Function |  |
| $\overline{O E}$ | LE | D | Q | O |  |  |
| X | X | X | X | Z | High Z |  |
| H | H | L | L | Z | High Z |  |
| H | H | H | H | Z | High Z |  |
| H | L | X | NC | Z | Latched |  |
| L | H | L | L | L | Transparent |  |
| L | H | H | H | H | Transparent |  |
| L | L | X | NC | NC | Latched |  |

H = HIGH Voltage Level
L = LOW Voltage Level
$X=$ Immaterial
$Z=$ High Impedance
NC $=$ No Change

## Logic Diagram

TL/F/10156-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate progagation delays.

## Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
-0.5 V to +7.0 V
DC Input Diode Current (IK)
$V_{1}=-0.5 \mathrm{~V}$
$V_{1}=V_{C C}+0.5 V$
DC Input Voltage ( $\mathrm{V}_{1}$ )
DC Output Diode Current (lok)
$\mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V}$
$V_{O}=V_{C C}+0.5 \mathrm{~V}$
DC Output Voltage (Vo)
DC Output Source or Sink Current (lo)
DC V CC or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )

| CDIP | $175^{\circ} \mathrm{C}$ |
| :--- | :--- |
| PDIP | $140^{\circ} \mathrm{C}$ |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating Conditions

## 54AC／74AC843 • 54ACT／74ACT843 8－Bit Transparent Latch

## General Description

The＇AC／＇ACT843 bus interface latch is designed to elimi－ nate the extra packages required to buffer existing latches and provide extra data width for wider address／data paths．
The＇AC／＇ACT843 is functionally and pin compatible with AMD＇s Am29843．

## Features

－＇ACT843 has TTL－compatible inputs
－TRI－STATE ${ }^{\circledR}$ outputs for bus interfacing

Ordering Code：See Section 8

Logic Symbols

TL／F／9800－3

## Connection Diagrams

| Pin Names | Description |
| :--- | :--- |
| $D_{0}-D_{7}$ | Data Inputs |
| $\mathrm{O}_{0}-\mathrm{O}_{7}$ | Data Outputs |
| $\overline{O E}$ | Output Enable |
| $\frac{L E}{C L R}$ | Latch Enable |
| $\overline{\text { PRE }}$ | Clear |

Functional Description
The 'AC/'ACT843 consists of nine D-type latches with TRISTATE outputs. The flip-flops appear transparent to the data when Latch Enable (LE) is HIGH. This allows asynchronous operation, as the output transition follows the data in transition. On the LE HIGH-to-LOW transition, the data that meets the setup times is latched. Data appears on the bus when the Output Enable ( $\overline{O E}$ ) is LOW. When $\overline{O E}$ is HIGH, the bus output is in the high impedance state. In
addition to the LE and $\overline{\mathrm{OE}}$ pins, the 'AC/'ACT843 has a Clear ( $\overline{\mathrm{CLR}})$ pin and a Preset ( $\overline{\mathrm{PRE}})$ pin. These pins are ideal for parity bus interfacing in high performance systems. When $\overline{\text { CLR }}$ is LOW, the outputs are LOW if $\overline{O E}$ is LOW. When $\overline{C L R}$ is HIGH, data can be entered into the latch. When PRE is LOW, the outputs are HIGH if $\overline{O E}$ is LOW. Preset overrides $\overline{\text { CLR. }}$

Function Tables

|  |  | Inputs |  |  | Internal | Outputs | Function |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

$Z=$ High Impedance
NC = No Change

## Logic Diagram

## Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (VCC)
DC Input Diode Current (IK)
$V_{1}=-0.5 \mathrm{~V}$
$V_{1}=V_{C C}+0.5 \mathrm{~V}$
DC Input Voltage ( $\mathrm{V}_{1}$ )
DC Output Diode Current (lok)
$\mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V}$
$V_{O}=V_{C C}+0.5 \mathrm{~V}$
DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current (lo)
DC V $\mathrm{V}_{\mathrm{CC}}$ or Ground Current per Output Pin (ICC or IGND)
Storage Temperature (TSTG)
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
$175^{\circ} \mathrm{C}$ $140^{\circ} \mathrm{C}$

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions

| Supply Voltage $\left(V_{C C}\right)$ | 2.0 V to 6.0 V |
| :--- | ---: |
| 'AC | 4.5 V to 5.5 V |
| 'ACT | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Input Voltage $\left(\mathrm{V}_{1}\right)$ | 0 V to $\mathrm{V}_{\mathrm{CC}}$ |
| Output Voltage $\left(\mathrm{V}_{\mathrm{O}}\right)$ |  |
| Operating Temperature $\left(\mathrm{T}_{\mathrm{A}}\right)$ | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| 74AC/ACT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |

Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'AC Devices $\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\text {CC }}$ $\mathrm{V}_{\mathrm{CC}} @ 3.3 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ ) 'ACT Devices
$\mathrm{V}_{\mathrm{IN}}$ from 0.8 V to 2.0 V $\mathrm{V}_{\mathrm{CC}}$ @ $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$

## 54ACT/74ACT845

8-Bit Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACT845 bus interface latch is designed to eliminate the extra packages required to buffer existing latches and provide easy expansion through multiple $\overline{\mathrm{OE}}$ controls.
The 'ACT845 is functionally and pin compatible with AMD's Am29845.

## Features

- 'ACT845 has TTL-compatible inputs

## Ordering Code: See Section 8

## Logic Symbols

| Pin Names | Description |
| :--- | :--- |
| $\mathrm{D}_{0}-\mathrm{D}_{7}$ | Data Inputs |
| $\mathrm{O}_{0}-\mathrm{O}_{7}$ | Data Outputs |
| $\overline{\mathrm{OE}}{ }_{1}-\overline{\mathrm{OE}_{3}}$ | Output Enables |
| $\frac{\mathrm{LE}}{\overline{\mathrm{CLR}}}$ | Latch Enable |
| $\overline{\mathrm{PRE}}$ | Clear |

Pin Assignment for LCC
$\mathrm{D}_{6} \mathrm{D}_{5} \mathrm{D}_{4} \mathrm{NC} \mathrm{D}_{3} \mathrm{D}_{2} \mathrm{D}_{1}$

## Functional Description

The 'ACT845 consists of eight D latches with TRI-STATE outputs. The flip-flops appear transparent to the data when Latch Enable (LE) is HIGH. This allows asynchronous operation as the output transition follows the data in transition.

On the LE HIGH-to-LOW transition, the data that meets the setup times is latched Data appears on the bus when the Output Enables ( $\mathrm{OE}_{1}, \overline{\mathrm{OE}}_{2}, \overline{\mathrm{OE}}_{3}$ ) are LOW. When any one of $\overline{\mathrm{OE}}_{1}, \overline{\mathrm{OE}}_{2}$ or $\overline{\mathrm{OE}}_{3}$ is HIGH, the bus output is in the high impedance state.

Function Table

|  |  | Inputs |  |  |  | Internal | Output |

NC = No Change

## Logic Diagram

TL/F/9896-4
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Ratings (Note 1)
If Milltary/Aerospace specifled devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
-0.5 V to +7.0 V
DC Input Diode Current ( $I_{K}$ )
$V_{1}=-0.5 \mathrm{~V}$
$-20 \mathrm{~mA}$
$V_{1}=V_{C C}+0.5 \mathrm{~V}$
$+20 \mathrm{~mA}$
DC Input Voltage ( $\mathrm{V}_{\mathrm{I}}$ )
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Diode Current (lok)

| $\mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V}$ | -20 mA |
| :---: | :---: |
| $V_{O}=V_{C C}+0.5 \mathrm{~V}$ | $+20 \mathrm{~mA}$ |
| DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ ) | -0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$ |
| DC Output Source or Sink Current (lo) | $\pm 50 \mathrm{~mA}$ |
| DC V CC or Ground Current Per Output Pin (ICC or IGND) | $\pm 50 \mathrm{~mA}$ |
| Storage Temperature ( $\mathrm{T}_{\mathrm{STG}}$ ) | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) |  |
| CDIP | $175^{\circ} \mathrm{C}$ |
| PDIP | $140^{\circ} \mathrm{C}$ |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )

## 'AC

'ACT
2.0 V to 6.0 V
4.5 V to 5.5 V

Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
OV to $\mathrm{V}_{\mathrm{CC}}$
OV to $\mathrm{V}_{\mathrm{CC}}$
Operating Temperature $\left(T_{A}\right)$ 74ACT
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
54ACT
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Minimum Input Edge Rate $(\Delta V / \Delta t)$
'AC Devices
$V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{C C}$
$\mathrm{V}_{\mathrm{CC}}$ @ $3.3 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate ( $\Delta \mathrm{V} / \Delta \mathrm{t}$ )
'ACT Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$V_{C C}$ @ 4.5V,5.5V $125 \mathrm{mV} / \mathrm{ns}$

## 54AC/74AC899 • 54ACT/74ACT899

## 9-Bit Latchable Transceiver

 with Parity Generator/Checker
## General Description

The 'AC/'ACT899 is a 9-bit to 9-bit parity transceiver with transparent latches. The device can operate as a feedthrough transceiver or it can generate/check parity from the 8 -bit data busses in either direction. The 'AC/'ACT899 features independent latch enables for the A-to-B direction and the B-to-A direction, a select pin for ODD/EVEN parity, and separate error signal output pins for checking parity.

## Features

■ Latchable transceiver with output sink of 24 mA

- Option to select generate parity and check or "feedthrough" data/parity in directions A-to-B or B-to-A
- Independent latch enable for A-to-B and B-to-A directions
- Select pin for ODD/EVEN parity

■ ERRA and ERRB output pins for parity checking

- Ability to simultaneously generate and check parity
- May be used in system applications in place of the '534 and '280
- May be used in system applications in place of the '657 and ' 373 (no need to change $T / \overline{\mathrm{A}}$ to check parity)
- 4 kV minimum ESD immunity

Ordering Code: See Section 8

## Logic Symbol

## Connection Diagram

## Pin Assignment for PCC

| Pin Names | Description |
| :---: | :---: |
| $\mathrm{A}_{0}-\mathrm{A}_{7}$ | A Bus Data Inputs/Data Outputs |
| $\mathrm{B}_{0}-\mathrm{B}_{7}$ | B Bus Data Inputs/Data Outputs |
| APAR, BPAR | A and B Bus Parity Inputs |
| ODD/EVEN | ODD/EVEN Parity Select, Active LOW for EVEN Parity |
| $\overline{\mathrm{GBA}}, \overline{\mathrm{GAB}}$ | Output Enables for A or B Bus, Active LOW |
| $\overline{\text { SEL }}$ | Select Pin for Feed-Through or Generate Mode, LOW for Generate Mode |
| LEA, LEB | Latch Enables for $A$ and $B$ Latches, HIGH for Transparent Mode |
| $\overline{\text { ERRA, }}$, $\overline{\text { RRB }}$ | Error Signals for Checking Generated Parity with Parity In, LOW if Error Occurs |

## Functional Description

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (VCC)
DC Input Diode Current ( $I_{\mathrm{K}}$ )

$$
\begin{aligned}
& V_{1}=-0.5 V \\
& V_{1}=V_{C C}+0.5 \mathrm{~V}
\end{aligned}
$$

DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
DC Output Diode Current (lok)

| $\begin{aligned} & V_{\mathrm{O}}=-0.5 \mathrm{~V} \\ & \mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V} \end{aligned}$ | $\begin{aligned} & -20 \mathrm{~mA} \\ & +20 \mathrm{~mA} \end{aligned}$ |
| :---: | :---: |
| DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ ) | -0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$ |
| DC Output Source or Sink Current (lo) | $\pm 50 \mathrm{~mA}$ |
| DC V ${ }_{C C}$ or Ground Current per Output Pin (ICC or IGND) | $\pm 50 \mathrm{~mA}$ |
| Storage Temperature (TSTG) | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| DC Latch-Up Source or Sink Current | $\pm 300 \mathrm{~mA}$ |
| Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) |  |
| CDIP | $175^{\circ} \mathrm{C}$ |
| PDIP | $140^{\circ} \mathrm{C}$ |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions

## ADVANCE INFORMATION

## 54AC/74AC2525 • 54AC/74AC2526 Minimum Skew Clock Driver

The 'AC2525 is a minimum skew clock driver with one input driving eight outputs specifically designed for signal generation and clock distribution applications. The 2525 is designed to distribute a single clock to eight separate receivers with low skew across all outputs during both the TPLH and TPHL transitions. The AC2526 is similar to the AC2525 but contains a multiplexed clock input to allow for systems with dual clock speeds or systems where a separate test clock has been implemented.

## Features

- Ideal for signal generation and clock distribution
- Guaranteed pin to pin and part to part skew

■ Multiplexed clock input ('2526)

- Guaranteed 2000 V minimum ESD protection
- 24 mA output drive capability

## 54AC/74AC2708•54ACT/74ACT2708 $64 \times 9$ First-In, First-Out Memory

## General Description

The 'AC/'ACT2708 is an expandable first-in, first-out memory organized as 64 words by 9 bits. An 85 MHz shift-in and 60 MHz shift-out typical data rate makes it ideal for highspeed applications. It uses a dual port RAM architecture with pointer logic to achieve the high speed with negligible fall-through time.
Separate Shift-In (SI) and Shift-Out (SO) clocks control the use of synchronous or asynchronous write or read. Other controls include a Master Reset ( $\overline{\mathrm{MR} \text { ) and Output Enable }}$ (OE) for initializing the internal registers and allowing the data outputs to be TRI-STATE ${ }^{\oplus}$. Input Ready (IR) and Output Ready (OR) signal when the FIFO is ready for I/O operations. The status flags HF and FULL indicate when the FIFO is full, empty or half full.
The FIFO can be expanded to provide different word lengths by tying off unused data inputs.

- Expandable in word width only
- 'ACT2708 has TTL-compatible inputs
- Asynchronous or synchronous operation
- Asynchronous master reset

■ Outputs source/sink 8 mA

- TRI-STATE outputs
- Full ESD protection
- Input and output pins directly in line for easy board layout
- TRW 1030 work-alike operation

## Applications

- High-speed disk or tape controllers
- A/D output buffers

■ High-speed graphics pixel buffer

- Video time base correction
- Digital filtering

## Features

■ 64-words by 9-bit dual port RAM organization
■ 85 MHz shift-in, 60 MHz shift-out data rate, typical

## Ordering Code: See Section 8

TL/F/10144-3

TL/F/10144-4

## Functional Description

## INPUTS

## Data Inputs ( $D_{0}-D_{8}$ )

Data inputs for 9 -bit wide data are TTL-compatible. Word width can be reduced by trying unused inputs to ground and leaving the corresponding outputs open.

## Reset (MR)

Reset is accomplished by pulsing the $\overline{M R}$ input LOW. During normal operation MR is HIGH. A reset is required after power up to guarantee correct operation. On reset, the data outputs go LOW, IR goes HIGH, OR goes LOW, FH and FULL go LOW. During reset, both internal read and write pointers are set to the first location in the array.

## Shift-In (SI)

Data is written into the FIFO by pulsing SI HIGH. When Shift-In goes HIGH, the data is loaded into an internal data latch. Data setup and hold times need to be adhered to with respect to the falling edge of SI . The write cycle is complete after the falling edge of SI. The shift-in is independent of any ongoing shift-out operation. After the first word has been written into the FIFO, the falling edge of SI makes HF go HIGH, indicating a non-empty FIFO. The first data word appears at the output after the falling edge of SI. After half the memory is filled, the next rising edge of SI makes FULL go HIGH indicating a half-full FIFO. When the FIFO is full, any further shift-ins are disabled.
When the FIFO is empty and $\overline{O E}$ is LOW, the falling edge of the first SI will cause the first data word just shifted-in to appear at the output, even though SO may be LOW.

## Shift-Out (SO)

Data is read from the FIFO by the Shift-Out signal provided the FIFO is not empty. SO going HIGH causes OR to go LOW indicating that output stage is busy. On the falling edge of SO, new data reaches the output after propagation delay $t_{\mathrm{D}}$. If the last data has been shifted-out of the memory, OR continues to remain LOW, and the last word shifted-out remains on the output pins.

## Output Enable ( $\overline{\mathrm{OE}}$ )

$\overline{\mathrm{OE}}$ LOW enables the TRI-STATE output buffers. When $\overline{\mathrm{OE}}$ is HIGH, the outputs are in a TRI-STATE mode.

## OUTPUTS

## Data Outputs $\left(\mathrm{O}_{0}-\mathrm{O}_{8}\right)$

Data outputs are enabled when $\overline{\mathrm{OE}}$ is LOW and in the TRISTATE condition when $\overline{O E}$ is HIGH.

## Input Ready (IR)

IR HIGH indicates data can be shifted-in. When SI goes HIGH, IR goes LOW, indicating input stage is busy. IR stays LOW when the FIFO is full and goes HIGH after the falling edge of the first shift-out.

## Output Ready (OR)

OR HIGH indicates data can be shifted-out from the FIFO. When SO goes HIGH, OR goes LOW, indicating output stage is busy. OR is LOW when the FIFO is reset or empty and goes HIGH after the falling edge of the first shift-in.

## Half-Full (HF)

This status flag along with the FULL status flag indicates the degree of fullness of the FIFO. On reset, HF is LOW; it rises on the falling edge of the first SI. The rising edge of the SI pulse that fills up the FIFO makes HF go LOW. Going from the empty to the full state with SO LOW, the falling edge of the first SI causes HF to go HIGH, the rising edge of the 33rd SI causes FULL to go HIGH, and the rising edge of the 64th SI causes HF to go LOW.
When the FIFO is full, HF is LOW and the falling edge of the first shift-out causes HF to go HIGH indicating a "non-full" FIFO.

## Full Flag (FULL)

This status flag along with the HF status flag indicates the degree of fullness of the FIFO. On reset, FULL is LOW. When half the memory is filled, on the rising edge of the next SI, the FULL flag goes HIGH. It remains set until the difference between the write pointer and the read pointer is less than or equal to one-half of the total memory of the device. The FULL flag then goes LOW on the rising edge of the next SO.

Status Flags Truth Table

| HF | FULL | Status Flag Condition |
| :--- | :--- | :--- |
| L | L | Empty |
| L | H | Full |
| H | L | $<32$ Locations Filled |
| H | H | Z32 Locations Filled |

Functional Description (Continued)

## MODES OF OPERATION

Mode 1: Shift in Sequence for FIFO Empty to Full Sequence of Operation

1. Input Ready is initially HIGH; HF and FULL flags are LOW. The FIFO is empty and prepared for valid data. OR is LOW indicating that the FIFO is not yet ready to output data.
2. Shift-In is set HIGH, and data is loaded into the FIFO. Data has to be settled $\mathrm{t}_{\mathrm{s}}$ before the falling edge of SI and held $t_{h}$ after.
3. İnput Ready (IR) goes LOW propagation delay $\mathrm{t}_{\mathrm{IR}}$ after SI goes HIGH: input stage is busy.
4. Shift-In is set LOW; IR goes HIGH indicating the FIFO is ready for additional data. Data just shifted-in arrives at output propagation delay tods after SI falls. OR goes HIGH propagation delay $t_{\mathrm{IOR}}$ after SI goes LOW, indicating the FIFO has valid data on its outputs. HF goes HIGH propagation delay $\mathrm{t}_{\mathrm{IE}}$ after SI falls, indicating the FIFO is no longer empty.
5. The process is repeated through the 64th data word. On the rising edge of the 33rd SI, FULL flag goes HIGH propagation delay $\mathrm{t}_{\mathrm{IHF}}$ after SI , indicating a half-full FIFO. HF goes LOW propagation delay $\mathrm{t}_{\mathrm{IF}}$ after the rising edge of the 64th pulse indicating that the FIFO is full. Any further shift-ins are disabled.

TL/F/10144-5
Note: SO and $\overline{O E}$ are LOW; $\overline{M R}$ is HIGH.
FIGURE 1. Modes of Operation Mode 1

## Functional Description (Continued)

## Mode 2: Master Reset

## Sequence of Operation

1. Input and Output Ready, HF and FULL can be in any state before the reset sequence with Master Reset (MR) HIGH.
2. Master Reset goes LOW and clears the FIFO, setting up all essential internal states. Master Reset must be LOW pulse width $\mathrm{t}_{\text {MRW }}$ before rising again.
3. Master Reset rises.
4. IR rises (if not HIGH already) to indicate ready to write state recovery time $\mathrm{t}_{\text {MRIRH }}$ after the falling edge of $\overline{\mathrm{MR}}$. Both HF and FULL will go LOW indicating an empty FIFO, occurring recovery times $t_{\text {MRE }}$ and $t_{\text {MRO }}$ respectively after the falling edge of $\overline{M R}$. OR falls recovery time $\mathrm{t}_{\text {MRORL }}$ after $\overline{M R}$ falls. Data at outputs goes LOW recovery time $\mathrm{t}_{\mathrm{MRONL}}$ after $\overline{\mathrm{MR}}$ goes LOW.
5. Shift-In can be taken HIGH after a minimum recovery time $\mathrm{t}_{\mathrm{MRSIH}}$ after $\overline{\mathrm{MR}}$ goes HIGH.

FIGURE 2. Mode of Operation Mode 2

## Functional Description (Continued)

Mode 3: With FIFO Full, Shift-In is Held HIGH In Anticipation of an Empty Location

## Sequence of Operation

1. The FIFO is initially full and Shift-In goes HIGH. OR is initially HIGH. Shift-Out is LOW. IR is LOW.
2. Shift-Out is pulsed HIGH, Shift-Out pulse propagates and the first data word is latched on the rising edge of SO. OR falls on this edge. On the falling edge of SO, the second data word appears after propagation delay $t_{D}$. New data is written into the FIFO after SO goes LOW.
3. Input Ready goes HIGH one fall-through time, $\mathrm{t}_{\mathrm{FT}}$, after the falling edge of SO. Also, HF goes HIGH one tof after SO falls, indicating that the FIFO is no longer full.
4. IR returns LOW puise width $t_{I P}$ after rising and shifting new data in. Also, HF returns LOW pulse width t 3 F after rising, indicating the FIFO is once more full.
5. Shift-In is brought LOW to complete the shift-in process and maintain normal operation

Note: $\overline{M R}$ and FULL are HIGH; $\overline{O E}$ is LOW.
FIGURE 3. Modes of Operation Mode 3

## Functional Description (Continued)

Mode 4: Shift-Out Sequence, FIFO Full to Empty

## Sequence of Operation

1. FIFO is initially full and OR is HIGH, indicating valid data is at the output. IR is LOW.
2. SO goes HIGH, resulting in OR going LOW one propagation delay, tor, after SO rises. OR LOW indicates output stage is busy.
3. SO goes LOW, new data reaches output one propagation delay, $t_{D}$, after SO falls; OR goes HIGH one propagation delay, tor, after SO falls and HF rises one propagation delay, tof, after SO falls. IR rises one fall-through time, $\mathrm{t}_{\mathrm{FT}}$, after SO falls.
4. Repeat process through the 64th SO pulse. FULL flag goes LOW one propagation delay, $\mathrm{t}_{\mathrm{OHF}}$, after the rising edge of 33rd SO, indicating that the FIFO is less than half full. On the falling edge of the 64th SO, HF goes LOW one propagation delay, toE, after SO, indicating the FIFO is empty. The SO pulse may rise and fall again with an attempt to unload an empty FIFO. This results in no change in the data on the outputs as the 64th word stays latched.

TL/F/10144-8
Note: SI and $\overline{\mathrm{OE}}$ are LOW; $\overline{\mathrm{MR}}$ is $\mathrm{HIGH} ; \mathrm{D}_{0}-\mathrm{D}_{8}$ are immaterial.
FIGURE 4. Modes of Operation Mode 4

## Functional Description (Continued)

Mode 5: With FIFO Empty, Shift-Out is Held HIGH in Anticipation of Data
Sequence of Operation

1. FIFO is initially empty; Shift-Out goes HIGH.
2. Shift-In pulse loads data into the FIFO and IR falls. HF rises propagation delay $\mathrm{t}_{\mathrm{X} 1}$ after the falling edge of SI .
3. OR rises a fall-through time of $\mathrm{t}_{\text {FTO }}$ after the falling edge of Shift-In, indicating that new data is ready to be output.
4. Data arrives at output one propagation delay, toD5, after the falling edge of Shift-In.
5. OR goes LOW pulse width top after rising and HF goes LOW pulse width $\mathrm{t}_{\mathrm{X} 3}$ after rising, indicating that the FIFO is empty once more.
6. Shift-Out goes LOW, necessary to complete the Shift-Out process.

TL/F/10144-9
Note: FULL is LOW; $\overline{M R}$ is HIGH; $\overline{O E}$ is LOW; $t_{D O F}=t_{\text {FTO }}-t_{O D 5}$. Data output transition-valid data arrives at output stage $t_{D O F}$ after $O R$ is HIGH.
FIGURE 5. Modes of Operation Mode 5

## FIFO Expansion

Word Width Expansion
Word width can be increased by connecting the corresponding input control signals of multiple devices. Flags can be monitored to obtain a composite signal by ANDing the corresponding flags.

TL/F/10144-10
Note: AND the corresponding flags to obtain a composite signal.
FIGURE 6. Word Width Expansion-64 x 18 FIFO

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

## 54ACT/74ACT2725

$512 \times 9$ First In, First Out Memory (FIFO)

## General Description

The $512 \times 9$ FIFO is a first-in, first-out dual port memory capable of asynchronous, simultaneous read and write. Other important features are: expansion capability in both the word depth and bit width, half-full flag capability in the single device mode, empty and full warning flags, ring pointers for fall-through time; it is suited for high-speed applications.

## Features

- First-in, first-out dual port memory
- $512 \times 9$ organization
- Low power consumption
- Asynchronous and simultaneous read and write
- Fully expandable by word depth and/or bit width
- Half-full flag capability in single device mode
- Empty and full warning flags
- Auto retransmit capability
- Outputs source/sink 8 mA
- 'ACT2725 has TTL-compatible inputs
- Pin and functionality compatible with IDT7201A

## Logic Symbol

TL/F/10138-3

| Pin Names | Description |
| :--- | :--- |
| $D_{0}-D_{8}$ | Data Inputs |
| $O_{0}-O_{8}$ | Data Outputs |
| $\bar{W}$ | Write Enable |

## 54ACT/74ACT2726 <br> $512 \times 9$ Bidirectional First In, First Out Memory (BIFIFO)

## General Description

The $512 \times 9$ FIFO is a first-in, first-out dual port memory capable of asynchronous, simultaneous read and write. Other important features are: expansion capability in both the word depth and bit width, half-full flag capability in the single device mode, empty and full warning flags, and ring pointers for zero fall-through time. There are two sets of bidirectional ports, each 9 bits wide, through which data flow can be controlled. A direction pin (DIR) controls the direction of the data: when the DIR is HIGH, $A$ is the input port and $B$ is the output port. When the DIR is LOW, the input port is B and output port is A. It is suited for high-speed applications.

## Logic Symbol

| Pin Names | Description |
| :--- | :--- |
| $D_{0}-D_{8}$ | Data Inputs |
| $O_{0}-O_{8}$ | Data Outputs |
| $\bar{W}$ | Write Enable |
| $\bar{R}$ | Read Enable |
| $\overline{X I}$ | Expansion In |
| $\overline{X O} / \overline{\mathrm{HF}}$ | Expansion Out, Half-Full Flag |
| $\overline{\mathrm{EF}}$ | Empty Flag |
| $\overline{\mathrm{FF}}$ | Full Flag |
| $\overline{\mathrm{RS}}$ | Reset |
| $\overline{\mathrm{DIR}}$ | Direction |

## Features

- First-in, first-out bidirectional memory
- $512 \times 9$ organization
- Low power consumption
- Asynchronous and simultaneous read and write
- Fully expandable by word depth and/or bit width
- Half-full flag capability in single device mode
- Master/slave multiprocessing applications
- Bidirectional and rate buffer applications
- Empty and full warning flags
- Outputs source/sink 8 mA
- 'ACT2726 has TTL-compatible inputs

## 54ACQ/74ACQ153 • 54ACTQ/74ACTQ153 Quiet Series Dual 4-Input Multiplexer

## General Description

The 'ACQ/'ACTQ153 is a high-speed dual 4 -input multiplexer with common select inputs and individual enable inputs for each section. It can select two lines of data from four sources. The two buffered outputs present data in the true (non-inverted) form. In addition to multiplexer operation, the 'ACQ/'ACTQ153 can act as a function generator and generate any two functions of three variables.

## Features

- Outputs source/sink 24 mA
- 'ACTQ153 has TTL-compatible inputs
- Guaranteed simultaneous switching noise level and dynamic threshold performance
- Guaranteed pin-to-pin skew AC performance
- Improved latch-up immunity

The information for the 'ACQ153 is advanced information only.
Ordering Code: See Section 8

## Functional Description

The 'ACQ/'ACTQ153 is a dual 4 -input multiplexer. It can select two bits of data from up to four sources under the control of the common Select inputs ( $\mathrm{S}_{0}, \mathrm{~S}_{1}$ ). The two 4-input multiplexer circuits have individual active-LOW Enables ( $\bar{E}_{a}, \overline{\mathrm{E}}_{\mathrm{b}}$ ) which can be used to strobe the outputs indepedently. When the Enables ( $\bar{E}_{a}, \bar{E}_{b}$ ) are HIGH, the corresponding outputs $Z_{a}, Z_{b}$ ) are forced LOW. The 'ACQ/'ACTQ153 is the logic implementation of a 2-pole, 4position switch, where the position of the switch is determined by the logic levels supplied to the Select inputs. The logic equations for the outputs are shown below.

$$
\begin{aligned}
\mathrm{Z}_{\mathrm{a}}= & \overline{\mathrm{E}}_{\mathrm{a}} \bullet\left(\mathrm{l}_{0 \mathrm{a}} \bullet \overline{\mathrm{~S}}_{1} \cdot \overline{\mathrm{~S}}_{0}+\mathrm{I}_{1 \mathrm{a}} \bullet \overline{\mathrm{~S}}_{1} \bullet \mathrm{~S}_{0}+\right. \\
& \left.\mathrm{I}_{2 \mathrm{a}} \cdot \mathrm{~S}_{1} \bullet \mathrm{~S}_{0}+\mathrm{I}_{3 \mathrm{a}} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{0}\right) \\
\mathrm{Z}_{\mathrm{b}}= & \overline{\mathrm{E}}_{\mathrm{b}} \bullet\left(\mathrm{l}_{0 \mathrm{~b}} \bullet \overline{\mathrm{~S}}_{1} \bullet \overline{\mathrm{~S}}_{0}+\mathrm{I}_{1 \mathrm{~b}} \bullet \overline{\mathrm{~S}}_{1} \bullet \mathrm{~S}_{0}+\right. \\
& \left.\mathrm{I}_{2 \mathrm{~b}} \cdot \mathrm{~S}_{1} \bullet \overline{\mathrm{~S}}_{0}+\mathrm{I}_{3 \mathrm{~b}} \bullet \mathrm{~S}_{1} \bullet \mathrm{~S}_{0}\right)
\end{aligned}
$$

## 54ACQ/74ACQ240•54ACTQ/74ACTQ240 Quiet Series Octal Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACQ/'ACTQ240 is an inverting octal buffer and line driver designed to be employed as a memory address driver, clock driver and bus oriented transmitter or receiver which provides improved PC board density. The 'ACQ/ 'ACTQ utilizes NSC Quiet Series technology to guarantee quiet output switching and improve dynamic threshold performance. FACT Quiet Series ${ }^{\text {TM }}$ features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- Guaranteed simultaneous switching noise level and dynamic threshold performance
■ Guaranteed pin-to-pin skew AC performance
- Improved latch-up immunity
- Inverting TRI-STATE outputs drive bus lines or buffer memory address registers
■ Outputs source/sink 24 mA
- Faster prop delays than the standard 'ACT240
- 4 kV minimum ESD immunity

## Ordering Code: See Section 8

## 54ACQ/74ACQ241•54ACTQ/74ACTQ241 Quiet Series Octal Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACQ/'ACTQ241 is an octal buffer and line driver designed to be employed as a memory address driver, clock driver and bus oriented transmitter or receiver which provides improved PC board density. The ACQ/ACTQ utilizes NSC Quiet Series technology to guarantee quiet output switching and improved dynamic threshold performance. FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- Guaranteed simultaneous switching noise level and dynamic threshold performance
■ Guaranteed pin-to-pin skew AC performance
- Improved latch-up immunity
- TRI-STATE® ${ }^{\circledR}$ outputs drive bus lines or buffer memory address registers
■ Outputs source/sink 24 mA
- Faster prop delays than the standard 'AC/'ACT241
- 4 kV minimum ESD immunity ('ACTQ)

Ordering Code: See Section 8

Note 1：Absolute maximum ratings are those values beyond which damage to the device may occur．The databook specifications should be met，without exception，to ensure that the system design is reliable over its power supply， temperature，and output／input loading variables．National does not recom－ mend operation of FACT circuits outside databook specifications．

## 54ACQ／74ACQ244 • 54ACTQ／74ACTQ244 Quiet Series Octal Buffer／Line Driver with TRI－STATE ${ }^{\circledR}$ Outputs

## General Description

The＇ACQ／＇ACTQ244 is an octal buffer and line driver de－ signed to be employed as a memory address driver，clock driver and bus oriented transmitter or receiver which pro－ vides improved PC board density．The ACQ／ACTQ utilizes NSC Quiet Series technology to guarantee quiet output switching and improved dynamic threshold performance． FACT Quiet Series ${ }^{\text {TM }}$ features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance．

## Features

Guaranteed simultaneous switching noise level and dy－ namic threshold performance
a Guaranteed pin－to－pin skew AC performance
－Improved latch－up immunity
－TRI－STATE ${ }^{\oplus}$ outputs drive bus lines or buffer memory address registers
－Outputs source／sink 24 mA
Faster prop delays than the standard＇AC／＇ACT244
－ 4 kV minimum ESD immunity

Ordering Code：See Section 8

DC Output Source or Sink Current (lo)
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$\pm 50 \mathrm{~mA}$
DC V CC or Ground Current per Output Pin (ICC or land)
Storage Temperature (TSTG)
DC Latch-Up Source or Sink Current
$\pm 300 \mathrm{~mA}$
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
$175^{\circ} \mathrm{C}$ PDIP
$140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACT circuits outside databook specifications.

## Recommended Operating Conditions

Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) 'ACQ
2.0 V to 6.0 V
'ACTQ
4.5 V to 5.5 V

Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
Operating Temperature $\left(T_{A}\right)$ 74ACQ/ACTQ
54ACQ/ACTQ
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Minimum Input Edge Rate $\Delta V / \Delta t$ 'ACQ Devices
$V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{C C}$ $\mathrm{V}_{\mathrm{CC}}$ @ $3.0 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate $\Delta \mathrm{V} / \Delta \mathrm{t}$
'ACTQ Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$V_{C C}$ @ 4.5V, $5.5 \mathrm{~V} \quad 125 \mathrm{mV} / \mathrm{ns}$

## 54ACQ/74ACQ245 • 54ACTQ/74ACTQ245 Quiet Series Octal Bidirectional Transceiver with TRI-STATE ${ }^{\circledR}$ Inputs/Outputs

## General Description

The 'ACQ/'ACTQ245 contains eight non-inverting bidirectional buffers with TRI-STATE outputs and is intended for bus-oriented applications. Current sinking capability is 24 mA at both the A and B ports. The Transmit/Receive (T/R) input determines the direction of data flow through the bidirectional transceiver. Transmit (active-HIGH) enables data from A ports to B ports; Receive (active-LOW) enables data from B ports to A ports. The Output Enable input, when HIGH, disables both A and B ports by placing them in a HIGH $Z$ condition.
The 'ACQ/'ACTQ utilizes NSC Quiet Series technology to guarantee quiet output switching and improve dynamic threshold performance. FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

© Guaranteed simultaneous switching noise level and dynamic threshold performance
■ Guaranteed pin-to-pin skew AC performance

* Improved latch-up immunity
© TRI-STATE outputs drive bus lines or buffer memory address registers
(1) Outputs source/sink 24 mA

■ Faster prop delays than the standard 'ACT245

- 4 kV minimum ESD immunity ('ACQ)

Ordering Code: See Section 8

Pin Assignment for DIP, Flatpak and SOIC

TL/F/10236-3

TL/F/10236-4
Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
-0.5 V to +7.0 V
DC Input Diode Current (IK)

$$
\begin{aligned}
& V_{1}=-0.5 V \\
& V_{1}=V_{C C}+0.5 V
\end{aligned}
$$

-20 mA
$+20 \mathrm{~mA}$
DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
-0.5 V to to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$\pm 50 \mathrm{~mA}$
$\pm 50 \mathrm{~mA}$
$-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$
DC Latch-Up Source or Sink Current
$\pm 300 \mathrm{~mA}$
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
CDIP
$175^{\circ} \mathrm{C}$
PDIP

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACT circuits outside databook specifications.

## Recommended Operating

 ConditionsSupply Voltage (VCC)
'ACQ

Input Voltage ( $\mathrm{V}_{1}$ )
2.0V to 6.0 V
4.5 V to 5.5 V

OV to $\mathrm{V}_{\mathrm{CC}}$
Output Voltage (Vo)
Operating Temperature $\left(T_{A}\right)$ 74ACQ/ACTQ
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Minimum Input Edge Rate $\Delta V / \Delta t$ 'ACQ Devices $\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\mathrm{CC}}$ $\mathrm{V}_{\mathrm{CC}}$ @ $3.0 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate $\Delta V / \Delta t$ 'ACTQ Devices $\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V $\mathrm{V}_{\mathrm{CC}}$ @ $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$

## 54ACQ/74ACQ273 • 54ACTQ/74ACTQ273 <br> Quiet Series Octal D Flip-Fiop

## General Description

The 'AC/'ACT273 has eight edge-triggered D-type flip-flops with individual $D$ inputs and $Q$ outputs. The common buffered Clock (CP) and Master Reset (MR) input load and reset (clear) all flip-flops simultaneously.
The register is fully edge-triggered. The state of each $D$ input, one setup time before the LOW-to-HIGH clock transition, is transferred to the corresponding flip-flop's Q output.
All outputs will be forced LOW independently of Clock or Data inputs by a LOW voltage level on the $\overline{M R}$ input. The device is useful for applications where the true output only is required and the Clock and Master Reset are common to all storage elements.
The 'ACQ/'ACTQ utilizes NSC Quiet Series technology to guarantee quiet output switching and improved dynamic The information for the ACQ273 is Advanced Information only.

threshold performance. FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- Guaranteed simultaneous switching noise level and dynamic threshold performance
- Guaranteed pin-to-pin skew AC performance
- Improved latch-up immunity
- Buffered common clock and asynchronous master reset

■ Outputs source/sink 24 mA

- Faster prop delays than the standard 'AC/'ACT273

口 4 kV minimum ESD immunity

## 54ACQ/74ACQ373 • 54ACTQ/74ACTQ373 <br> Quiet Series Octal Transparent Latch <br> with TRI-STATE® Outputs

## General Description

The 'ACQ/'ACTQ373 consists of eight latches with TRISTATE outputs for bus organized system applications. The latches appear transparent to the data when Latch Enable (LE) is HIGH. When LE is low, the data satisfying the input timing requirements is latched. Data appears on the bus when the Output Enable (OE) is LOW. When OE is HIGH, the bus output is in the high impedance state.
The 'ACQ/'ACTQ373 utilizes NSC Quiet Series technology to guarantee quiet output switching and improve dynamic threshold performance. FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- Guaranteed simultaneous switching noise level and dynamic threshold performance
- Guaranteed pin-to-pin skew AC performance
- Improved latch up immunity
- Eight latches in a single package
- TRI-STATE outputs drive bus lines or buffer memory address registers
■ Outputs source/sink 24 mA
- Faster prop delays than the standard 'AC/'ACT373
- 4 kV minimum ESD immunity ('ACQ)

Ordering Code: See Section 8

## Logic Symbols

## Connection Diagrams

Pin Assignment for DIP, Flatpak and SOIC

Pin Assignment for LCC and PCC
$\mathrm{D}_{3} \mathrm{D}_{2} \mathrm{O}_{2} \mathrm{O}_{1} \mathrm{D}_{1}$

## Functional Description

The 'ACQ/'ACTQ373 contains eight D-type latches with TRI-STATE standard outputs. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent, i.e., a latch output will change state each time its D input changes. When LE is LOW, the latches store the information that was present on the D inputs a setup time preceding the HIGH-to-LOW transition of LE. The TRI-STATE standard outputs are controlled by the Output Enable ( $\overline{\mathrm{OE}}$ ) input. When $\overline{\mathrm{OE}}$ is LOW, the standard outputs are in the 2 -state mode. When $\overline{O E}$ is HIGH, the standard outputs are in the high impedance mode but this does not interfere with entering new data into the latches.

Truth Table

| Inputs |  |  | Outputs |
| :---: | :---: | :---: | :---: |
| $L E$ | $\overline{O E}$ | $D_{\boldsymbol{n}}$ | $O_{\boldsymbol{n}}$ |
| $X$ | $H$ | $X$ | $Z$ |
| $H$ | $L$ | $L$ | $L$ |
| $H$ | $L$ | $H$ | $H$ |
| $L$ | $L$ | $X$ | $O_{0}$ |

$H=$ HIGH Voltage Level
L = LOW Voltage Level
Z $=$ High Impedance
$X=$ Immaterial
$\mathrm{O}_{0}=$ Previous $\mathrm{O}_{0}$ before HIGH to Low transition of Latch Enable

## 54ACQ/74ACQ374 • 54ACTQ/74ACTQ374 <br> Quiet Series Octal D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACQ/'ACTQ374 is a high-speed, low-power octal Dtype flip-flop featuring separate D-type inputs for each flipflop and TRI-STATE outputs for bus-oriented applications. A buffered Clock (CP) and Output Enable ( $\overline{\mathrm{OE}})$ are common to all flip-flops.
The 'ACQ/'ACTQ374 utilizes Quiet Series technology to guarantee quiet output switching and improve dynamic threshold performance. FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

■ Guaranteed simultaneous switching noise level and dynamic threshold performance

- Guaranteed pin-to-pin skew AC performance
- Improved latch-up immunity

■ Buffered positive edge-triggered clock

- TRI-STATE outputs drive bus lines or buffer memory address registers
- Outputs source/sink 24 mA
- Faster prop delays than the standard 'AC/'ACT374
- 4 kV minimum ESD immunity

## Ordering Code: See Section 8

## Logic Symbols

Pin Assignment for DIP, Flatpak and SOIC

TL/F/10238-3

| Pin Names | Description |
| :--- | :--- |
| $D_{0}-D_{7}$ | Data Inputs |
| $C P$ | Clock Pulse Input |
| $\overline{O E}$ | TRI-STATE Output Enable Input |
| $O_{0}-O_{7}$ | TRI-STATE Outputs |

## Functional Description

The 'ACQ/'ACTQ374 consists of eight edge-triggered flipflops with individual D-type inputs and TRI-STATE true outputs. The buffered clock and buffered Output Enable are common to all flip-flops. The eight flip-flops will store the state of their individual $D$ inputs that meet the setup and hold time requirements on the LOW-to-HIGH Clock (CP) transition. With the Output Enable ( $\overline{\mathrm{OE}}$ ) LOW, the contents of the eight flip-flops are available at the outputs. When the $\overline{\mathrm{OE}}$ is HIGH, the outputs go to the high impedance state. Operation of the $\overline{\mathrm{OE}}$ input does not affect the state of the flip-flops.

## Logic Diagram

Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specifled devices are required, please contact the National Semiconductor Sales Office/Distributors for avallability and specifications.
Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ )
-0.5 V to +7.0 V
DC Input Diode Current (IK)
$V_{1}=-0.5 \mathrm{~V}$
$V_{1}=V_{C C}+0.5 V$
DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
DC Output Diode Current (Iok)

$$
V_{O}=-0.5 \mathrm{~V}
$$

$-20 \mathrm{~mA}$
$+20 \mathrm{~mA}$
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$-20 \mathrm{~mA}$

$$
V_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
$$

$+20 \mathrm{~mA}$
DC Output Voltage (V)
-0.5 V to to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Source
or Sink Current (lo)
$\pm 50 \mathrm{~mA}$
DC $V_{C C}$ or Ground Current per Output Pin (ICC or IGND)
$\pm 50 \mathrm{~mA}$
Storage Temperature (TSTG)
DC Latch-Up Source or Sink Current
$-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$

Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
CDIP
$175^{\circ} \mathrm{C}$
$140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating Conditions

Supply Voltage (VCC) 'ACQ 2.0V to 6.0 V
'ACTQ
Input Voltage ( $V_{1}$ ) 4.5 V to 5.5 V OV to $\mathrm{V}_{\mathrm{Cc}}$
Output Voltage (VO) OV to $\mathrm{V}_{\mathrm{Cc}}$
Operating Temperature $\left(T_{A}\right)$ 74ACQ/ACTQ
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ 54ACQ/ACTQ
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Minimum Input Edge Rate $\Delta \mathrm{V} / \Delta \mathrm{t}$ 'ACQ Devices $V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{C C}$ $\mathrm{V}_{\mathrm{CC}}$ @ $3.0 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate $\Delta \mathrm{V} / \Delta \mathrm{t}$ 'ACTQ devices $\mathrm{V}_{\mathrm{in}}$ from 0.8 V to 2.0 V $\mathrm{V}_{\mathrm{CC}}$ @ $4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$

## 54ACQ/74ACQ377 • 54ACTQ/74ACTQ377 Quiet Series Octal D Flip-Flop with Clock Enable

## General Description

The 'ACQ/'ACTQ377 has 8 edge-triggered D-type flip-flops with individual $D$ inputs and $Q$ outputs. The common buffered Clock (CP) input loads all flip-flops simultaneously, when the Clock Enable ( $\overline{\mathrm{CE}}$ ) is low. The register is fully edge-triggered. The state of each D input, one set-up time before the LOW-to-HIGH clock transition, is transferred to the corresponding flip-flop's Q output. The $\overline{C E}$ input must be stable only one set-up time prior to the LOW-to-HIGH clock transition for predictable operation.
The 'ACQ/'ACTQ utilizes NSC Quiet Series technology to guarantee quiet output switching and improved dynamic threshold performance. FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

■ Guaranteed simultaneous switching noise level and dynamic threshold performance

- Guaranteed pin-to-pin skew AC performance
- Ideal for addressable register applications
- Clock enable for address and data synchronization applications
- Eight edge-triggered D flip-flops
- Buffered common clock
- Outputs source/sink 24 mA
- Faster prop delays than the standard 'AC/'ACT377
- 4 kV minimum ESD immunity

## 54ACQ/74ACQ533 • 54ACTQ/74ACTQ533 Quiet Series Octal Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACQ/'ACTQ533 consists of eight latches with TRISTATE outputs for bus organized system applications. The flip-flops appear transparent to the data when Latch Enable (LE) is HIGH. When LE is low, the data satisfying the input timing requirements is latched. Data appears on the bus when the Output Enable (OE) is LOW. When OE is HIGH, the bus output is in the high impedance state.
The 'ACQ/'ACTQ533 utilizes NSC Quiet Series technology to guarantee quiet output switching and improve dynamic threshold performance. FACT Quiet Series ${ }^{\text {TM }}$ features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

■ Guaranteed simultaneous switching noise level and dynamic threshold performance

- Guaranteed pin-to-pin skew AC performance
- Improved latch up immunity
- Eight latches in a single package
- TRI-STATE outputs drive bus lines or buffer memory address registers
■ Outputs source/sink 24 mA
- Inverted version of the 'ACQ/'ACTQ373
- 4 kV minimum ESD immunity

Ordering Code: See Section 8

$\mathrm{D}_{5} \overline{\mathrm{O}}_{5} \overline{\mathrm{O}}_{6} \mathrm{D}_{6} \mathrm{D}_{7}$

## Functional Description

The 'ACQ/'ACTQ533 contains eight D-type latches with TRI-STATE standard outputs. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent, i.e., a latch output will change state each time its D input changes. When LE is LOW, the latches store the information that was present on the $D$ inputs a setup time preceding the HIGH-to-LOW transition of LE. The TRI-STATE standard outputs are controlled by the Output Enable ( $\overline{\mathrm{OE}}$ ) input. When $\overline{\mathrm{OE}}$ is LOW, the standard outputs are in the 2-state mode. When $\overline{O E}$ is HIGH, the standard outputs are in the high impedance mode but this does not interfere with entering new data into the latches.

Truth Table

| Inputs |  |  | Outputs |
| :---: | :---: | :---: | :---: |
| $L E$ | $\overline{O E}$ | $D_{\mathbf{n}}$ | $\overline{\mathbf{O}}_{\boldsymbol{n}}$ |
| $X$ | $H$ | $X$ | $Z$ |
| $H$ | $L$ | $L$ | $H$ |
| $H$ | $L$ | $H$ | $L$ |
| $L$ | $L$ | $X$ | $\bar{O}_{\mathbf{0}}$ |

$H=$ HIGH Voltage Level
L = LOW Voltage Level
$Z=$ High Impedance
$X=$ Immaterial
$\bar{\delta}_{0}=$ Previous $\bar{O}_{0}$ before HIGH to Low transition of Latch Enable

## Logic Diagram

TL/F/10630-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

| Absolute Maximum Rating (Note 1) |  |
| :---: | :---: |
| If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications. |  |
| Supply Voltage (VCC) | -0.5 V to +7.0 V |
| DC Input Diode Current ( $l_{1 /}$ ) |  |
| $\mathrm{V}_{1}=-0.5 \mathrm{~V}$ | -20 mA |
| $V_{1}=V_{C C}+0.5 \mathrm{~V}$ | $+20 \mathrm{~mA}$ |
| DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ ) | -0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$ |
| DC Output Diode Current (lok) |  |
| $\mathrm{V}_{\mathrm{O}}=-0.5 \mathrm{~V}$ | -20 mA |
| $\mathrm{V}_{\mathrm{O}}=\mathrm{V}_{\text {CC }}+0.5 \mathrm{~V}$ | $+20 \mathrm{~mA}$ |
| DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ ) | -0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$ |
| DC Output Source or Sink Current (lo) | $\pm 50 \mathrm{~mA}$ |
| DC VCC or Ground Current per Output Pin (ICC or IGND) | $\pm 50 \mathrm{~mA}$ |
| Storage Temperature (TSTG) | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| DC Latchup Source or Sink Current | $\pm 300 \mathrm{~mA}$ |
| Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) |  |
| CDIP | $175^{\circ} \mathrm{C}$ |
| PDIP | $140^{\circ} \mathrm{C}$ |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating

 Conditions| Supply Voltage (VCC) |  |
| :--- | ---: |

## 54ACQ/74ACQ534•54ACTQ/74ACTQ534 Quiet Series Octal D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACQ/'ACTQ534 is a high-speed, low-power octal Dtype flip-flop featuring separate D-type inputs for each flipflop and TRI-STATE outputs for bus-oriented applications. A buffered Clock (CP) and Output Enable ( $\overline{\mathrm{OE}}$ ) are common to all flip-flops. The 'ACQ/'ACTQ534 is the same as the 'ACQ/ 'ACTQ374 except that the outputs are inverted.
The 'ACQ/'ACTQ534 utilizes Quiet Series technology to guarantee quiet output switching and improve dynamic threshold performance. FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- Guaranteed simultaneous switching noise level and dynamic threshold performance
- Guaranteed pin-to-pin skew AC performance
- Improved latch-up immunity
- Buffered positive edge-triggered clock
- TRI-STATE outputs for bus-oriented applications
- Inverted output version of the 'ACQ/'ACTQ374
. Faster prop delays than the standard 'ACT534
- 4 kV minimum ESD immunity

## Ordering Code: See Section 8

$D_{5} \overline{\mathrm{O}}_{5} \overline{\mathrm{O}}_{6} \mathrm{D}_{6} \mathrm{D}_{7}$

## Functional Description

The 'ACQ/'ACTQ534 consists of eight D-type flip-flops with individual inputs and TRI-STATE complementary outputs. The buffered clock and buffered Output Enable are common to all flip-flops. The eight flip-flops will store the state of their individual D inputs that meet the setup and hold times
requirements on the LOW-to-HIGH Clock (CP) transition. With the Output Enable ( $\overline{O E}$ ) LOW, the contents of the eight flip-flops are available at the outputs. When the $\overline{\mathrm{OE}}$ is HIGH, the outputs go to the high impedance state. Operation of the $\overline{\mathrm{OE}}$ input does not affect the state of the flip-flops.

## Logic Diagram

TL/F/10247-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.
Function Table

| Inputs |  |  | Output |
| :---: | :---: | :---: | :---: |

$$

$\pm 300 \mathrm{~mA}$
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
$175^{\circ} \mathrm{C}$
PDIP
$140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating Conditions

## 54ACQ／74ACQ543 • 54ACTQ／74ACTQ543 Quiet Series Octal Registered Transceiver with TRI－STATE ${ }^{\circledR}$ Outputs

## General Description

The ACQ／ACTQ543 is a non－inverting octal transceiver containing two sets of D－type registers for temporary stor－ age of data flowing in either direction．Separate Latch En－ able and Output Enable inputs are provided for each regis－ ter to permit independent input and output control in either direction of data flow．
The ACQ／ACTQ utilizes NSC Quiet Series technology to guarantee quiet output switching and improved dynamic threshold performance．FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance．

## Features

－Guaranteed simultaneous switching noise level and dynamic threshold performance
－Guaranteed pin－to－pin skew AC performance
－8－bit octal latched transceiver
－Separate controls for data flow in each direction
－Back－to－back registers for storage
－Outputs source／sink 24 mA
－ 4 kV minimum ESD immunity

## 54ACQ/74ACQ563 • 54ACTQ/74ACTQ563 Quiet Series Octal Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACQ/'ACTQ563 is a high speed octal latch with buffered common Latch Enable (LE) and buffered common Output Enable ( $\overline{\mathrm{OE}}$ ) inputs. The 'ACQ/'ACTQ563 is functionally identical to the 'ACQ/'ACTQ573, but with inverted outputs. The ACQ/ACTQ utilizes NSC Quiet Series technology to guarantee quiet output switching and improved dynamic threshold performance. FACT Quiet Series ${ }^{\text {TM }}$ features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

■ Guaranteed simultaneous switching noise level and dynamic threshold perforfmance
■ Guaranteed pin-to-pin skew AC performance

- Improved latch-up immunity
a Inputs and outputs on opposite sides of package allow easy interface with microprocessors
■ Outputs source/sink 24 mA
- Faster prop delays than standard ACT563
$\square$ Functionally identical to the ACQ/ACTQ573 but with inverted outputs
口 4 kV minimum ESD immunity

Ordering Code: See Section 8

## Logic Symbols

Connection Diagrams
Pin Assignment for DIP, Flatpak and SOIC

TL/F/10631-3

Pin Assignment for LCC

TL/F/10631-4

Functional Description
The 'ACQ/'ACTQ563 contains eight D-type latches with TRI-STATE complementary outputs. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent, i.e., a latch output will change state each time its D input changes. When LE is LOW the latches store the information that was present on the D inputs a setup time preceding the HIGH-toLOW transition of LE. The TRI-STATE buffers are controlled by the Output Enable ( $\overline{O E}$ ) input. When $\overline{O E}$ is LOW, the buffers are in the bi-state mode. When $\overline{\text { OE }}$ is HIGH the buffers are in the high impedance mode but that does not interfere with entering new data into the latches.

Function Table

| Inputs |  |  | Internal | Outputs | Function |
| :---: | :---: | :---: | :---: | :---: | :--- |
| $\overline{\text { OE }}$ | LE | D | Q | O |  |
| H | X | X | X | Z | High-Z |
| H | H | L | H | Z | High-Z |
| H | H | H | L | Z | High-Z |
| H | L | X | NC | Z | Latched |
| L | H | L | H | H | Transparent |
| L | H | H | L | L | Transparent |
| L | L | X | NC | NC | Latched |

$\mathrm{H}=\mathrm{HIGH}$ Voltage Level
$\mathrm{L}=$ LOW Voltage Level
$\mathrm{X}=$ Immaterial
$\mathrm{Z}=$ High Impedance
$\mathrm{NC}=$ No Change

## Logic Diagram

Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Rating (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

## Supply Voltage (VCC)

DC Latchup Source or Sink Current
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) $\begin{array}{ll}\text { CDIP } & 175^{\circ} \mathrm{C} \\ \text { PDIP } & 140^{\circ} \mathrm{C}\end{array}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

Recommended Operating Conditions

## 54ACQ/74ACQ564 • 54ACTQ/74ACTQ564 <br> Quiet Series Octal D Flip-Flop <br> with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACTQ564 is a high speed octal D-type flip-flop with buffered common clock (CP) and a buffered common Output Enable (OE). The information presented to the D inputs is stored in the flip-flops on the low-to-high clock (CP) transition. The 'ACQ/'ACTQ564 utilizes NSC Quiet Series technology to guarantee quiet output switching and improved dynamic threshold performance. FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- Guaranteed simultaneous switching noise level and dynamic threshold performance
- Guaranteed pin-to-pin skew AC performance
- Improved latch-up immunity
- Inputs and outputs on opposite sides of package allow easy interface with $\mu$ P's
- Outputs source/sink 24 mA
- Faster prop delays than the standard 'ACT564
- 4 kV minimum ESD immunity

## Ordering Code: See Section 8

## Functional Description

The 'ACQ/'ACTQ564 consists of eight edge-triggered flipflops with individual D-type inputs and TRI-STATE true outputs. The buffered clock and buffered Output Enable are common to all flip-flops. The eight flip-flops will store the state of their individual $D$ inputs that meet the setup and hold time requirements on the LOW-to-HIGH Clock (CP) transition. With the Output Enable ( $\overline{\mathrm{OE}}$ ) LOW, the contents of the eight flip-flops are available at the outputs. When the $\overline{\mathrm{OE}}$ is HIGH, the outputs go to the high impedance state. Operation of the $\overline{O E}$ input does not affect the state of the flip-flops.

Function Table

| Inputs |  |  | Internal | Outputs | Function |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\overline{\mathrm{OE}}$ | CP | D | Q | $\mathrm{O}_{\mathrm{N}}$ |  |

TL/F/10632-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

## Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
-0.5 V to +7.0 V
DC Input Diode Current ( $l_{1 K}$ )
$V_{1}=-0.5 \mathrm{~V}$

- 20 mA
$V_{1}=V_{C C}+0.5 \mathrm{~V}$
$+20 \mathrm{~mA}$

DC Input Voltage ( $\mathrm{V}_{1}$ )
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Diode Current (lok)
$V_{O}=-0.5 \mathrm{~V}$

$$
-20 \mathrm{~mA}
$$

$V_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
$+20 \mathrm{~mA}$
DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
-0.5 V to to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Source or Sink Current (lo)
$\pm 50 \mathrm{~mA}$
DC V ${ }_{C C}$ or Ground Current
per Output Pin (lcc or land)
$\pm 50 \mathrm{~mA}$
Storage Temperature (TSTG)
$-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$
DC Latch-Up Source or Sink Current
$\pm 300 \mathrm{~mA}$
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )

| CDIP | $175^{\circ} \mathrm{C}$ |
| :--- | :--- |
| PDIP | $140^{\circ} \mathrm{C}$ |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## 54ACQ/74ACQ573 • 54ACTQ/74ACTQ573 Quiet Series Octal Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACQ/'ACTQ573 is a high-speed octal latch with buffered common Latch Enable (LE) and buffered common Output Enable ( $\overline{\mathrm{OE}}$ ) inputs. The 'ACQ/'ACTQ573 is functionally identical to the 'ACQ/'ACTQ373 but with inputs and outputs on opposite sides of the package. The 'ACQ/'ACTQ utilizes NSC Quiet Series technology to guarantee quiet output switching and improved dynamic threshold performance. FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- Guaranteed simultaneous switching raise level and dynamic threshold performance
- Guaranteed pin-to-pin skew AC performance
- Improved latch-up immunity
- Inputs and outputs on opposite sides of package allow easy interface with microprocessors
■ Outputs source/sink 24 mA
- Faster prop delays than standard 'ACT573
- 4 kV minimum ESD immunity

Ordering Code: See Section 8

## Logic Symbols

Pin Assignment for DIP, Flatpak and SOIC

TL/F/10633-3

| Pin Names | Description |
| :--- | :--- |
| $\mathrm{D}_{0}-\mathrm{D}_{7}$ | Data Inputs |
| $\frac{\mathrm{LE}}{}$ | Latch Enable Input |
| $\overline{\mathrm{OE}}$ | TRI-STATE Output Enable Input |
| $\mathrm{O}_{0}-\mathrm{O}_{7}$ | TRI-STATE Latch Outputs |

TL/F/10633-4

## Functional Description

The 'ACQ/'ACTQ573 contains eight D-type latches with TRI-STATE output buffers. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent, i.e., a latch output will change state each time its D input changes. When LE is LOW the latches store the information that was present on the $D$ inputs a setup time preceding the HIGH-to-LOW transition of LE. The TRI-STATE buffers are controlled by the Output Enable ( $\overline{\mathrm{OE}}$ ) input. When $\overline{\mathrm{OE}}$ is LOW, the buffers are enabled. When $\overline{O E}$ is HIGH the buffers are in the high impedance mode but this does not interfere with entering new data into the latches.

## Truth Table

| Inputs |  |  | Outputs |
| :---: | :---: | :---: | :---: |
| $\overline{\mathbf{O E}}$ | LE | D | $\mathbf{O}_{\boldsymbol{n}}$ |
| L | $H$ | $H$ | $H$ |
| L | $H$ | L | L |
| L | L | X | $O_{0}$ |
| H | X | X | Z |

H = HIGH Voltage
L = LOW Voltage
$\mathrm{Z}=$ High Impedance
$X=$ Immaterial
$\mathrm{O}_{0}=$ Previous $\mathrm{O}_{0}$ before HIGH-to-LOW transition of Latch Enable

## Logic Diagram

Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Rating (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Supply Voltage (VCC)
DC Input Diode Current ( $l_{\mathrm{IK}}$ )

$$
\begin{array}{ll}
V_{1}=-0.5 \mathrm{~V} & -20 \mathrm{~mA} \\
V_{1}=V_{C C}+0.5 V & +20 \mathrm{~mA}
\end{array}
$$

DC Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
-0.5 V to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$
DC Output Diode Current (lok)

$$
\begin{aligned}
& V_{\mathrm{O}}=-0.5 \mathrm{~V} \\
& \mathrm{~V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}
\end{aligned}
$$

$$
-20 \mathrm{~mA}
$$

$$
+20 \mathrm{~mA}
$$

DC Output Voltage ( $\mathrm{V}_{\mathrm{O}}$ )
DC Output Source or Sink Current (lo)
DC V CC or Ground Current per Output Pin (ICC or IGND)
-0.5 V to to $\mathrm{V}_{\mathrm{CC}}+0.5 \mathrm{~V}$

Storage Temperature (TSTG)
DC Latchup Source or Sink Current
$\pm 300 \mathrm{~mA}$ Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ ) CDIP
$175^{\circ} \mathrm{C}$ PDIP
$140^{\circ} \mathrm{C}$
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## Recommended Operating Conditions

Supply Voltage (VCC) 'ACQ
'ACTQ
Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
Output Voltage (VO)
Operating Temperature $\left(T_{A}\right)$
74ACQ/ACTQ
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
54ACQ/ACTQ
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Minimum Input Edge Rate $\Delta V / \Delta t$
'ACQ Devices
$\mathrm{V}_{\text {IN }}$ from $30 \%$ to $70 \%$ of $\mathrm{V}_{\mathrm{CC}}$
$\mathrm{V}_{\mathrm{CC}}$ @ 3.0V, 4.5V, 5.5V
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate $\Delta V / \Delta t$
'ACTQ Devices
$\mathrm{V}_{\mathrm{IN}}$ from 0.8 V to 2.0 V
$\mathrm{V}_{\mathrm{CC}}$ @ 4.5V,5.5V
$125 \mathrm{mV} / \mathrm{ns}$

## 54ACQ/74ACQ574 • 54ACTQ/74ACTQ574 <br> Quiet Series Octal D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACQ/'ACTQ574 is a high-speed, low-power octal Dtype flip-flop with a buffered Common Clock (CP) and a buffered common Output Enable (味). The information presented to the D inputs is stored in the flip-flops on the LOW-toHIGH clock (OP) transition.
'ACQ/'ACTQ574 utilizes Quiet Series technology to guarantee quiet output switching and improve dynamic threshold performance. FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.
The 'ACQ/'ACTQ574 is functionally identical to the 'ACTQ374 but with different pin-out.

## Features

■ Guaranteed simultaneous switching noise level and dynamic threshold performance

- Guaranteed pin-to-pin skew AC performance
- Inputs and outputs on opposite sides of the package allowing easy interface with microprocessors
- Functionally identical to the 'ACQ/ACTQ374
- TRI-STATE outputs drive bus lines or buffer memory address registers
■ Outputs source/sink 24 mA
- Faster prop delays than the standard 'AC/'ACT574
- 4 kV minimum ESD immunity

## Ordering Code: See Section 8

## Functional Description

The 'ACQ/'ACTQ574 consists of eight edge-triggered flipflops with individual D-type inputs and TRI-STATE true outputs. The buffered clock and buffered Output Enable are common to all flip-flops. The eight flip-flops will store the state of their individual $D$ inputs that meet the setup and hold time requirements on the LOW-to-HIGH Clock (CP) transition. With the Output Enable ( $\overline{\mathrm{OE}}$ ) LOW, the contents of the eight flip-flops are available at the outputs. When $\overline{O E}$ is HIGH, the outputs go to the high impedance state. Operation of the $\overline{\mathrm{OE}}$ input does not affect the state of the flipflops.

Function Table

| Inputs |  |  | Internal | Outputs | Function |
| :---: | :---: | :---: | :---: | :---: | :--- |

## Logic Diagram

TL/F/10634-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circults outside databook specifications.

## Recommended Operating Conditions

Supply Voltage ( $\mathrm{V}_{\mathrm{CC}}$ ) 'ACQ
2.0 V to 6.0 V
'ACTQ
Input Voltage ( $\mathrm{V}_{\mathrm{l}}$ )
4.5 V to 5.5 V

Output Voltage (VO)
Operating Temperature $\left(T_{A}\right)$ 74ACQ/ACTQ
$-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ 54ACQ/ACTQ
$-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
Minimum Input Edge Rate $\Delta V / \Delta t$ 'ACQ Devices $V_{\text {IN }}$ from $30 \%$ to $70 \%$ of $V_{C C}$ $\mathrm{V}_{\mathrm{CC}}$ @ $3.0 \mathrm{~V}, 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$
Minimum Input Edge Rate $\Delta \mathrm{V} / \Delta \mathrm{t}$ 'ACTQ Devices
$\mathrm{V}_{\text {IN }}$ from 0.8 V to 2.0 V
$\mathrm{V}_{\mathrm{CC}} @ 4.5 \mathrm{~V}, 5.5 \mathrm{~V}$
$125 \mathrm{mV} / \mathrm{ns}$

## 54ACQ／74ACQ646 • 54ACTQ／74ACTQ646 Quiet Series Octal Transceiver／Register with TRI－STATE ${ }^{\circledR}$ Outputs

## General Description

The＇ACQ／＇ACTQ646 consist of registered bus transceiver circuits，with outputs，D－type flip－flops，and control circuitry providing multiplexed transmission of data directly from the input bus or from the internal storage registers．Data on the A or B bus will be loaded into the respective registers on the LOW－to－HIGH transition of the appropriate clock pin（CPAB or CPBA）．
The＇ACQ／＇ACTQ utilizes NSC Quiet Series technology to guarantee quiet output switching and improved dynamic threshold performance．FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance．
The information on the ACQ646 is Advanced Information only．

## Features

■ Guaranteed simultaneous switching noise level and dy－ namic threshold performance
－Guaranteed pin－to－pin skew AC performance
－Independent registers for A and B busses
－Multiplexed real－time and stored data transfers
－ 300 mil slim dual－in－line package
－Outputs source／sink 24 mA
－Faster prop delays than the standard＇AC／＇ACT646
－ 4 kV minimum ESD immunity

The information on the ACQ646 is Advanced Information only．

## 54ACQ/74ACQ657 • 54ACTQ/74ACTQ657 Quiet Series Octal Bidirectional Transceiver with 8-Bit Parity Generator/Checker and TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACQ/'ACTQ657 contains eight non-inverting buffers with TRI-STATE outputs and an 8-bit parity generator/ checker. Intended for bus oriented applications, the device combines the '245 and the '280 functions in one package.
The 'ACQ/'ACTQ utilizes NSC Quiet Series technology to guarantee quiet output switching and improved dynamic threshold performance. FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- Guaranteed simultaneous switching noise level and dynamic threshold performance
- Guaranteed pin-to-pin skew AC performance
- Combines the '245 and the '280 functions in one package
■ 300 mil 24 -pin slim dual-in-line package
- Outputs source/sink 24 mA
- 4 kV minimum ESD immunity

The Information on the ACQ657 Is Advanced Information only.

## 54ACQ/74ACQ821 Quiet Series 10-Bit D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACQ821 is a 10 -bit $D$ flip-flop with non-inverting TRISTATE outputs arranged in a broadside pinout. The ACQ821 utilizes NSC Quiet Series technology to guarantee quiet output switching and improved dynamic threshold performance. FACT Quiet SeriesTM features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- Guaranteed simultaneous switching noise level and dynamic threshold performance
- Guaranteed pin-to-pin skew AC performance
- Non-inverting TRI-STATE outputs for bus interfacing
- 4 kV minimum ESD immunity
- Outputs source/sink 24 mA

Functionally identical to the AM29821

## 54ACTQ/74ACTQ827 Quiet Series 10-Bit Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACTQ827 10-bit bus buffer provides high performance bus interface buffering for wide data/address paths or buses carrying parity. The 10 -bit buffers have NOR output enables for maximum control flexibility. The 'ACTQ827 utilizes NSC Quiet Series technology to guarantee quiet output switching and improved dynamic threshold performance. FACT Quiet Series ${ }^{\text {TM }}$ feature GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- Guaranteed simultaneous switching noise level and dynamic threshold performance
- Guaranteed pin-to-pin skew AC performance
m Inputs and outputs on opposite sides of package allow easy interface with microprocessors
I Improved latch-up immunity
- Outputs source/sink 24 mA
. Functionally and pin-compatible to AMD's AM29827
a 'ACTQ827 has TTL-compatible inputs
- 4 kV minimum ESD immunity

## 54ACTQ/74ACTQ841 Quiet Series 10-Bit Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'ACTQ841 bus interface latch is designed to eliminate the extra packages required to buffer existing latches and provide extra data width for wider address/data paths or buses carrying parity. The ' 841 is a 10-bit transparent latch, a 10 -bit version of the '373. The 'ACTQ841 utilizes NSC Quiet Series technology to guarantee quiet output switching and improved dynamic threshold performance, FACT Quiet Series ${ }^{\text {TM }}$ features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- Guaranteed simultaneous switching noise level and dynamic threshold performance
- Guaranteed pin-to-pin skew AC performance
- Inputs and outputs on opposite sides of package allow easy interface with microprocessors
( Improved latch-up immunity

## 54FCT/74FCT138 <br> 1-of-8 Decoder/Demultiplexer

## General Description

The 'FCT138 is a high-speed 1-of-8 decoder/demultiplexer. This device is ideally suited for high-speed bipolar memory chip select address decoding. The multiple input enables allow parallel expansion to a 1-of-24 decoder using just three 'FCT138 devices or a 1-of-32 decoder using four 'FCT138 devices and one inverter.
FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT138 is pin and functionally equivalent to IDT 54FCT/74FCT138
- Demultiplexing capability
- Multiple input enable for easy expansion
- Active LOW mutually exclusive outputs
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{I}_{\mathrm{OL}}=48 \mathrm{~mA}$ (Com), 32 mA (Mil)
- CMOS power levels
- ESD immunity $\geq 4 \mathrm{kV}$ typ

■ Military Product compliant to MIL-STD 883 and Standard Military Drawing \#5962-87654

## 54FCT/74FCT240 <br> Inverting Octal Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT240 is an inverting octal buffer and line driver designed to be employed as a memory address driver, clock driver and bus oriented transmitter or receiver which provides improved PC board density.
FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

■ NSC 54FCT/74FCT240 is pin and functionally equivalent to IDT 54FCTT/74FCT240

- Inverting TRI-STATE outputs

Input clamp diodes to limit bus reflections

- TTL/CMOS input and output level compatible
- $\mathrm{IOL}_{\mathrm{OL}}=64 \mathrm{~mA}$ (commercial), 48 mA (military)
- CMOS power levels
- ESD immunity $\geq 4 \mathrm{kV}$ typ
- Military product compliant to MIL-STD 883 and standard military drawing \# 5962-87655

## Ordering Code: See Section 8

DC Characteristics for 'FCT Family Devices (Continued)
Typical values are at $\mathrm{V}_{\mathrm{CC}}=5.0 \mathrm{~V}, 25^{\circ} \mathrm{C}$ ambient and maximum loading. For test conditions shown as Max, use the value specified for the appropriate device type: $\mathrm{Com}: \mathrm{V}_{\mathrm{CC}}=5.0 \mathrm{~V} \pm 5 \%, \mathrm{~T}_{\mathrm{A}}=0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$; Mil: $\mathrm{V}_{\mathrm{CC}}=5.0 \mathrm{~V} \pm 10 \%, \mathrm{~T}_{\mathrm{A}}=-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}, \mathrm{V}_{\mathrm{HC}}=\mathrm{V}_{\mathrm{CC}}-0.2 \mathrm{~V}$.

Note 1: Maximum test duration not to exceed one second, not more than one output shorted at one time.
Note 2: This parameter guaranteed but not tested.
Note 3: Per TTL driven input $\left(V_{I N}=3.4 \mathrm{~V}\right)$; all other inputs at $\mathrm{V}_{\mathrm{CC}}$ or GND.
Note 4: This parameter is not directly testable, but is derived for use in Total Power Supply calculations.
Note 5: Values for these conditions are examples of the Icc formula. These limits are guaranteed but not tested.
Note 6: $\mathrm{I}_{\mathrm{C}}=$ I $_{\text {QUIESCENT }}+\mathrm{I}_{\text {INPUTS }}+\mathrm{l}_{\text {DYNAMIC }}$
$I_{C}=I_{C C}+\Delta I_{C C} D_{H} N_{T}+I_{C C D}\left(f_{C P} / 2+f_{1} N_{l}\right)$
$I_{C C}=$ Quiescent Current
$\Delta I_{C C}=$ Power Supply Current for a TTL High Input $\left(V_{\mathbb{I N}}=3.4 \mathrm{~V}\right)$
$D_{H}=$ Duty Cycle for TTL Inputs High
$N_{T}=$ Number of Inputs at $D_{H}$
$I_{C C D}=$ Dynamic Current Caused by an Input Transition Pair (HLH or LHL)
$\mathrm{f}_{\mathrm{CP}}=$ Clock Frequency for Register Devices (Zero for Non-Register Devices)
$f_{f}=$ Input Frequency
$N_{l}=$ Number of Inputs at $f_{1}$
All currents are milliamps and all frequencies are in megahertz.
Note 7: For $54 F C T, I_{C C D}=0.40 \mathrm{~mA} / \mathrm{MHz}$.
Refer to applicable standard military drawing or NSC Table I for test conditions and $\mathrm{I}_{\mathrm{C}} / \mathrm{I}_{\mathrm{CC}}$ limits.

## 54FCT/74FCT241

## Octal Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT241 is an octal buffer and line driver designed to be employed as a memory address driver, clock driver and bus-oriented transmitter or receiver which provides improved PC board density.
FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT241 is pin and functionally equivalent to IDT 54FCT/74FCT241
■ Non-inverting TRI-STATE outputs drive bus lines or buffer memory address registers
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{l}_{\mathrm{OL}}=64 \mathrm{~mA}$ (Com), 48 mA (Mil)
- CMOS power levels
- ESD immunity $\geq 4 \mathrm{kV}$ typical
- Military product compliant to MIL-STD 883

## Ordering Code: See Section 8

Logic Symbol

## 54FCT／74FCT244

## Octal Buffer／Line Driver with TRI－STATE® Outputs

## General Description

The＇FCT244 is an octal buffer and line driver designed to be employed as a memory address driver，clock driver and bus－oriented transmitter／receiver which provides improved PC board density．
FACTTM FCT utilizes NSC quiet series technology to pro－ vide improved quiet output switching and dynamic threshold performance．
FACT FCT and GTOTM output control and undershoot cor－ rector in addition to a split ground bus for superior perform－ ance．

## Features

－NSC 54FCT／74FCT244 is pin and functionally equiva－ lent to IDT 54FCT／74FCT244
－Controlled output edge rates and undershoot for im－ proved noise immunity．Internal split ground for im－ proved noise immunity
－Input clamp diodes to limit bus reflections
－TTL／CMOS input and output level compatible
－ $\mathrm{l}_{\mathrm{OL}}=64 \mathrm{~mA}$（commercial）and 48 mA （military）
－CMOS power levels
－ESD immunity $\geq 4 \mathrm{kV}$ typ
－Military product compliant to MIL－STD 883C and stan－ dard military drawing \＃5962－87630

Ordering Code：See Section 8

## 54FCT/74FCT245

Octal Bidirectional Transceiver with TRI-STATE ${ }^{\circledR}$ Inputs/Outputs

## General Description

The 'FCT245 contains eight non-inverting bidirectional buffers with TRI-STATE outputs and is intended for bus-oriented applications. The Transmit/Receive (T/伿) input determines the direction of data flow through the bidirectional transceiver. Transmit (active-HIGH) enables data from A ports to B ports; Receive (active-LOW) enables data from B ports to A ports. The Output Enable input, when HIGH, disables both $A$ and $B$ ports by placing them in a HIGH $Z$ condition.
FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- NSC54FCT/74FCT245 is pin and functionally equivalent to IDT54FCT/74FCT245
- Controlled output edge rates and undershoot for improved noise immunity. Internal split ground for improved noise immunity.
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{l}_{\mathrm{OL}}=64 \mathrm{~mA}$ (commercial) and 48 mA (military)
- CMOS power levels

■ ESD immunity $\geq 4 \mathrm{kV}$ typ

- Military product compliant to MIL-STD 883 and Standard Military Drawing \# 5962-87629

## Ordering Code: See Section 8

## 54FCT/74FCT273 Octal D Flip-Flop

## General Description

The 'FCT273 has eight edge-triggered D-type flip-flops with individual D inputs and Q outputs. The common buffered Clock (CP) and Master Reset (MR) input load and reset (clear) all flip-flops simultaneously.
The register is fully edge-triggered. The state of each D input, one setup time before the LOW-to-HIGH clock transition, is transferred to the corresponding flip-flop's Q output.
All outputs will be forced LOW independently of Clock or Data inputs by a LOW voltage level on the $\overline{M R}$ input. The device is useful for applications where the true output only is required and the Clock and Master Reset are common to all storage elements.

## Features

- Ideal buffer for MOS microprocessor or memory
- Eight edge-triggered D flip-flops
- Buffered common clock
- Buffered, asynchronous master reset
- TTL input and output level compatible
- TTL levels accept CMOS levels
- $\mathrm{lOL}=48 \mathrm{~mA}$ (Com), 32 mA (Mil)
- NSC 54/74FCT273 is pin and functionally equivalent to IDT 54/74FCT273

Ordering Code: See Section 8

## 54FCT/74FCT373

## Octal Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT373 consists of eight latches with TRI-STATE outputs for bus organized system applications. The flip-flops appear transparent to the data when Latch Enable (LE) is HIGH. When LE is LOW, the data that meets the setup time is latched. Data appears on the bus when the Output Enable $(\overline{\mathrm{OE}})$ is LOW. When $\overline{\mathrm{OE}}$ is HIGH, the bus output is in the high impedance state.
FACT FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT373 is pin and functionally equivalent to IDT 54FCT/74FCT373
- Controlled output edge rates and undershoot for improved noise immunity. Internal split ground for improved noise immunity
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{IOL}=48 \mathrm{~mA}$ (commercial) and 32 mA (military)
- CMOS power levels
- ESD immunity $\geq 4 \mathrm{kV}$ typ
- Military product compliant to MIL-STD 883 and standard military drawing \#5962-87644

## Ordering Code: See Section 8

TL/F/10242-4

## Functional Description

The 'FCT373 contains eight D-type latches with TRI-STATE standard outputs. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent, i.e., a latch output will change state each time its $D$ input changes. When LE is LOW, the latches store the information that was present on the D inputs a setup time preceding the HIGH-to-LOW transition of LE. The TRI-STATE standard outputs are controlled by the Output Enable ( $\overline{\mathrm{OE}}$ ) input. When $\overline{\mathrm{OE}}$ is LOW, the standard outputs are in the 2-state mode. When $\overline{\mathrm{OE}}$ is HIGH, the standard outputs are in the high impedance mode but this does not interfere with entering new data into the latches.

Truth Table

| Inputs |  |  | Outputs |
| :---: | :---: | :---: | :---: |
| LE | $\overline{\mathbf{O E}}$ | $\mathbf{D}_{\boldsymbol{n}}$ | $\mathbf{O}_{\boldsymbol{n}}$ |
| X | H | X | Z |
| $H$ | L | L | L |
| $H$ | L | H | H |
| L | L | X | $\mathrm{O}_{\mathbf{n}}$ |

$H=$ HIGH Voltage Level
L = LOW Voltage Level
$Z=$ High Impedance
$X=$ Immaterial
$\mathrm{O}_{\mathrm{n}}=$ Previous $\mathrm{O}_{\mathrm{n}}$ before HIGH to Low transition of Latch Enable

## Logic Diagram

[^113]Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

## Absolute Maximum Rating (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Terminal Voltage with Respect to GND (VTERM)

| 54FCT | -0.5 V to +7.0 V |
| :--- | ---: |
| 74FCT | -0.5 V to +7.0 V |
| Temperature under Bias (TBIAS) | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| 74FCT | $-65^{\circ} \mathrm{C}$ to $+135^{\circ} \mathrm{C}$ |
| 54FCT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Storage Temperature (TSTG) | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| 74FCT | 0.5 W |
| 54FCT | 120 mA |
| Power Dissipation (PT) |  |
| DC Output Current (louT) |  |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. Exposure to absolute maximum rating conditions for extended periods may affect reliability. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables.

Recommended Operating Conditions

| Supply Voltage (VCC) |  |
| :--- | ---: |
| 54 FCT | 4.5 V to 5.5 V |

## 54FCT/74FCT374 Octal D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT374 is a high-speed, low-power octal D-type flipflop featuring separate D-type inputs for each flip-flop and TRI-STATE outputs for bus-oriented applications. A buffered Clock (CP) and Output Enable ( $\overline{\mathrm{OE}}$ ) are common to all flip-flops.
FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT374 is pin and functionally equivalent to IDT 54FCT/74FCT374
- Controlled output edge rates and undershoot for improved noise immunity. Internal split ground for improved noise immunity
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- lol $=48 \mathrm{~mA}$ (commercial) and 32 mA (military)
- CMOS power levels
- ESD immunity $\geq 4 \mathrm{kV}$ typ
- Military product compliant to MIL-STD 883 and standard military drawing \#5962-87628

Ordering Code: See Section 8

## Logic Symbols

IEEE/IEC

Connection Diagrams

TL/F/10243-4

## Functional Description

The 'FCT374 consists of eight edge-triggered flip-flops with individual D-type inputs and TRI-STATE true outputs. The buffered clock and buffered Output Enable are common to all flip-flops. The eight flip-flops will store the state of their individual $D$ inputs that meet the setup and hold time requirements on the LOW-to-HIGH Clock (CP) transition. With the Output Enable ( $\overline{\mathrm{OE}}$ ) LOW, the contents of the eight flipflops are available at the outputs. When the $\overline{\mathrm{OE}}$ is HIGH, the outputs go to the high impedance state. Operation of the $\overline{\mathrm{OE}}$ input does not affect the state of the flip-flops.

## Truth Table

## 54FCT377/74FCT377

## Octal D Flip-Flop with Clock Enable

## General Description

The FCT377 has eight edge-triggered, D-type flip-flops with individual $D$ inputs and $Q$ outputs. The common buffered Clock (CP) input loads all flip-flops simultaneously, when the Clock Enable ( $\overline{\mathrm{CE}}$ ) is LOW.
The register is fully edge-triggered. The state of each D input, one setup time before the LOW-to-HIGH clock transition, is transferred to the corresponding flip-flop's Q output. The $\overline{C E}$ input must be stable only one setup time prior to the LOW-to-HIGH clock transition for predictable operation.
FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT377 is pin and functionally equivalent to IDT 54FCT/74FCT377
- Ideal for addressable register applications
- Clock enables for address and data synchronization applications
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{lOL}^{2}=48 \mathrm{~mA}$ (com), 32 mA (mil)
- CMOS power levels
- ESD immunity $\geq 4 \mathrm{kV}$ typ
- Military product compliant to MIL-STD 883 and Standard Military Drawing \# 5962-87627

## Ordering Code: See Section 8

## 54FCT/74FCT521

 8-Bit Identity Comparator
## General Description

The 'FCT521 is an expandable 8-bit comparator. It compares two words of up to eight bits each and provides a LOW output when the two words match bit for bit. The expansion input $\bar{T}_{A}=\mathrm{B}$ also serves as an active LOW enable input.
FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT521 is pin and functionally equivalent to IDT 54FCT/74FCT521
- Expandable to any word length
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{l}_{\mathrm{OL}}=48 \mathrm{~mA}$ (Com), 32 mA (Mil)
- CMOS power levels
- 4 kV minimum ESD immunity
- Military Product compliant to MIL-STD 883

## 54FCT/74FCT533

## Octal Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT533 consists of eight latches with TRI-STATE outputs for bus organized system applications. The flip-flops appear transparent to the data when Latch Enable (LE) is HIGH. When LE is LOW, the data that meets the setup times is latched. Data appears on the bus when the Output Enable ( $\overline{\mathrm{OE}}$ ) is LOW. When $\overline{\mathrm{OE}}$ is HIGH the bus output is in the high impedance state. FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance. FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance. The 'FCT533 is the same as the 'FCT373, except that the outputs are inverted.

## Features

- NSC 54FCT/74FCT533 is pin and functionally equivalent to IDT 54FCT/74FCT533
- TRI-STATE outputs for bus interfacing
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{I}_{\mathrm{OL}}=48 \mathrm{~mA}$ (Com), 32 mA (Mil)
- CMOS power levels

■ ESD immunity 4 kV typ

- Military product compliant to MIL-STD 883 and Standard Military Drawing \#5962-88651

$\mathrm{H}=\mathrm{HIGH}$ Voltage Level
L = LOW Voltage Level
$X=\operatorname{Logic}(0)$ or logic(1) must be valid Input Level
$\mathrm{O}_{\mathrm{n}}=$ Previous $\overline{\mathrm{O}}_{\mathrm{n}}$ before high to low transition of latch enable.

## Functional Description

The 'FCT533 contains eight D-type latches with TRI-STATE output buffers. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent and the latch output will change state each time its D input changes. When LE is LOW, the latches store the information that was present on the $D$ in-
puts a setup time preceding the HIGH-to-LOW transition of LE. The TRI-STATE buffers are controlled by the Output Enable ( $\overline{\mathrm{OE}}$ ) input. When $\overline{\mathrm{OE}}$ is LOW the latch contents are presented inverted at the outupts $\overline{\mathrm{O}}_{7}-\overline{\mathrm{O}}_{0}$. When $\overline{\mathrm{OE}}$ is HIGH the buffers are in the high impedance mode but this does not interfere with entering new data into the latches.

## 54FCT/74FCT534

Octal D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT534 is a high-speed, low-power octal D-type flipflop featuring separate D-type inputs for each flip-flop and TRI-STATE outputs for bus-oriented applications. A buffered Clock (CP) and Output Enable ( $\overline{\mathrm{OE}}$ ) are common to all flip-flops. FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance. The 'FCT534 is the same as the 'FCT374 except that the outputs are inverted.

## Features

- NSC 54/74FCT534 is pin and functionally equivalent to IDT 54/74FCT534

■ Edge-triggered D-type inputs

- Buffered positive edge-triggered clock
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{IOL}_{\mathrm{OL}}=48 \mathrm{~mA}$ (com), 32 mA (mil)
- CMOS power levels
(asD immunity $\geq 4 \mathrm{kV}$ typ
■ Military product compliant to MIL-STD-883

Ordering Code: See Section 8

## Functional Description

The 'FCT534 consists of eight edge-triggered flip-flops with individual D-type inputs and TRI-STATE complementary outputs. The buffered clock and buffered Output Enable are common to all flip-flops. The eight flip-flops will store the state of their individual $D$ inputs that meet the setup and hold times requirements on the LOW-to-HIGH Clock (CP)
transition. With the Output Enable ( $\overline{\mathrm{OE}})$ LOW, the contents of the eight flip-flops are available at the outputs. When the $\overline{\mathrm{OE}}$ is HIGH, the outputs go to the high impedance state. Operation of the $\overline{\mathrm{OE}}$ input does not affect the state of the flip-flops.

## Logic Diagram

Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.
Function Table

| Inputs |  |  | Output |
| :---: | :---: | :---: | :---: |
| $\mathbf{C P}$ | OE | $\mathbf{D}$ | $\overline{\mathbf{O}}$ |
| $\sim$ | L | H | L |
| $\sim$ | L | L | H |
| L | L | X | $\overline{\mathrm{O}}_{0}$ |
| X | H | X | Z |

$H=H I G H$ Voltage Level
L = LOW Voltage Level
X = Immaterial
$\widetilde{\sim}=$ LOW-to-HIGH Clock Transition
$Z=$ High Impedance
$\overline{\mathrm{O}}_{0}=$ Value stored from previcus clock cycle

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. Exposure to absolute maximum rating conditions for extended periods may affect reliability. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables.

## Recommended Operating Conditions

| Supply Voltage $\left(V_{C C}\right)$ | 4.5 V to 5.5 V |
| :--- | ---: |

## 54FCT540

## Inverting Octal Buffer/Line Driver

 with TRI-STATE ${ }^{\circledR}$ Outputs
## General Description

The 'FCT540 is an inverting octal buffer and line driver designed to be employed as a memory address driver, clock driver and bus oriented transmitter or receiver which provides improved PC board density.
The FACT540 is functionally equivalent to the FCT240 while providing broadside pinout.
The FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features undershoot corrector and a split ground bus for superior performance.

## Features

NSC 54FCT540 is pin and functionally equivalent to IDT 54FCT540

- Controlled output edge rates and undershoot for improved noise immunity. Internal split ground for improved noise immunity
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{l}_{\mathrm{OL}}=48 \mathrm{~mA}$
- CMOS power levels
- 2 kV minimum ESD immunity
- Military product compliant to MIL-STD 883 and Standard Military Drawing \#5962-89767

Ordering Code: See Section 8

## 54FCT541

Non-Inverting Octal Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT541 is a non-inverting octal buffer and line driver designed to be employed as a memory address driver, clock driver and bus oriented transmitter or receiver which provides improved PC board density.
The FCT541 is functionally equivalent to the FCT 241 with the exception of packaging, inputs and outputs are on the opposite side of the package.
FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features undershoot corrector and split ground bus for superior performance.

## Features

- NSC 54FCT541 is pin and functionally equivalent to IDT 54FCT541
- Input clamp diodes to limit bus reflections

TTL/CMOS input and output level compatible

- $\mathrm{IOL}_{\mathrm{OL}}=48 \mathrm{~mA}$
- CMOS power levels
- 2 kV minimum ESD immunity
- Military product compliant to MIL-STD 883 and standard military drawing \# 5962-89766

## Ordering Code: See Section 8

## Logic Symbol

## 54FCT/74FCT543

## Octal Registered Transceiver

## General Description

The 'FCT543 octal transceiver contains two sets of D-type latches for temporary storage of data flowing in either direction. Separate Latch Enable and Output Enable inputs are provided for each register to permit independent control of inputting and outputting in either direction of data flow.
FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT543 is pin and functionally equivalent to IDT 54FCT/74FCT543
- Back to back registers for storage
- Separate controls for data flow in each direction
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{l}_{\mathrm{OL}}=64 \mathrm{~mA}$ (com), 48 mA (mil)
- CMOS power levels
- 4 kV minimum ESD immunity
- Military Product compliant to MIL-STD 883

## 54FCT/74FCT563

## Octal Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT563 is a high-speed octal latch with buffered common Latch Enable (LE) and buffered common Output Enable ( $\overline{\mathrm{OE}}$ ) inputs.
FACT FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.

FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.
The 'FCT563 device is functionally identical to the 'FCT573, but with inverted outputs.

## Features

■ Inputs and outputs on opposite side of package allow easy interface with microprocessors

- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible

■ $\mathrm{I}_{\mathrm{OL}}=48 \mathrm{~mA}$ (Com), 32 mA (Mil)

- CMOS power levels
- ESD immunity $\geq 4$ kV typ

M Military product compliant to MIL-STD-883

## Ordering Code: See Section 8

## Logic Symbols

## Connection Diagrams

Pin Assignment for DIP, Flatpak and SOIC

TL/F/10670-3

TL/F/10670-4

## Functional Description

The 'FCT563 contains eight D-type latches with TRI-STATE complementary outputs. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent, i.e., a latch output will change state each time its D input changes. When LE is LOW the latches store the information that was present on the D inputs a setup time preceding the HIGH-to-LOW transition of LE. The TRI-STATE buffers are controlled by the Output Enable ( $\overline{O E}$ ) input. When $\overline{O E}$ is LOW, the buffers are in the TRI-STATE mode. When OE is HIGH the buffers are in the high impedance mode but that does not interfere with entering new data into the latches.

Function Table

| Inputs |  |  | Outputs | Function |
| :---: | :---: | :---: | :---: | :--- |
| $\overline{\mathbf{O E}}$ | LE | D | $\mathbf{O}$ |  |
| H | X | X | Z | High-Z |
| L | H | L | H | Transparent |
| L | H | H | L | Transparent |
| L | L | X | NC | Latched |

$H=$ HIGH Voltage Level
$\mathrm{L}=$ LOW Voltage Level
$\mathrm{X}=$ Immaterial
$\mathrm{Z}=$ High Impedance
$\mathrm{NC}=$ No Change

## Logic Diagram

Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Terminal Voltage with Respect to GND (VTERM)

| 54FCT | -0.5 V to +7.0 V |
| :--- | ---: |
| 74 FCT | -0.5 V to +7.0 V |
| Temperature under Bias (T $\mathrm{T}_{\text {BIAS }}$ ) | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| 74FCT | $-65^{\circ} \mathrm{C}$ to $+135^{\circ} \mathrm{C}$ |
| 54 FCT |  |
| Storage Temperature (TSTG) | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| 74 FCT | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| 54FCT | 0.5 W |
| Power Dissipation (PT) | 120 mA |
| DC Output Current (lOUT) |  |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. Exposure to absolute maximum rating conditions for extended periods may affect reliability. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables.

Recommended Operating Conditions

| Supply Voltage (VCC) |  |
| :--- | ---: |
| 54 FCT | 4.5 V to 5.5 V |
| 74 FCT | 4.75 V to 5.25 V |
| Input Voltage | 0 V to V CC |
| Output Voltage | 0 V to VCC |
| Operating Temperature $\left(\mathrm{T}_{\mathrm{A}}\right)$ |  |
| 54 FCT | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| 74 FCT | $0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$ |
| Junction Temperature ( $\left.\mathrm{T}_{\mathrm{J}}\right)$ |  |
| CDIP | $175^{\circ} \mathrm{C}$ |
| PDIP | $140^{\circ} \mathrm{C}$ |

## 54FCT/74FCT564

## Octal D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT564 is a high-speed, low power octal flip-flop with a buffered common Clock (CP) and a buffered common Output Enable ( $\overline{\mathrm{OE}}$ ). The information presented to the D inputs is stored in the flip-flops on the LOW-to-HIGH Clock (CP) transition.
FACT FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

The 'FCT564 device is functionally identical to the 'FCT574, but with inverted outputs.

## Features

NSC 54FCT/74FCT564 is pin and functionally equivalent to IDT 54FCT/74FCT564

- TRI-STATE outputs for bus-oriented applications
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{I}_{\mathrm{OL}}=48 \mathrm{~mA}$ (com), 32 mA (mil)
(1) CMOS power levels
- ESD immunity $\geq 4 \mathrm{kV}$ typ
- Military product compliant to MIL-STD 883

## Ordering Code: See Section 8

## Logic Symbols

54FCT/74FCT573

## Octal Latch with TRI-STATE®

## General Description

The 'FCT573 is a high-speed octal latch with buffered common Latch Enable (LE) and buffered common Output Enable ( $\overline{\mathrm{OE}}$ ) inputs.
FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.
The 'FCT573 is functionally identical to the 'FCT373 but has inputs and outputs on opposite sides.

## Outputs

## Ordering Code: See Section 8

## Logic Symbols

## Features

■ NSC 54/74FCT573 is pin and functionally equivalent to IDT 54/74FCT573

- TRI-STATE outputs for bus interfacing
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{l}_{\mathrm{OL}}=48 \mathrm{~mA}$ (Com), 32 mA (Mil)
- CMOS power levels
- ESD immunity $\geq 4 \mathrm{kV}$ typ
- Military Product compliant to MIL-STD-883 and Standard Military Drawing \#5962-88639

| $\mathrm{O}_{0}-\mathrm{O}_{7}$ | TRI-STATE Latch Outputs |

TL/F/10672-4

## Functional Description

The FCT573 contains eight D-type latches with TRI-STATE output buffers. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent, and the latch output will change state each time its D input changes. When LE is LOW the latches store the information that was present on the D inputs a setup time preceding the HIGH-to-LOW transition of LE. The TRI-STATE buffers are controlled by the Output Enable ( $\overline{(\mathrm{OE})}$ input. When $\overline{\mathrm{OE}}$ is LOW, the latch contents are presented inverted at the outputs $\overline{\mathrm{O}}_{7}-\overline{\mathrm{O}}_{0}$. When $\overline{\mathrm{OE}}$ is HIGH the buffers are in the high impedance mode but this does not interfere with entering new data into the latches.

Truth Table

| Inputs |  |  | Outputs |
| :---: | :---: | :---: | :---: |
| $\overline{O E}$ | LE | D | $\mathbf{O}_{\boldsymbol{n}}$ |
| L | $H$ | $H$ | $H$ |
| L | $H$ | $L$ | $L$ |
| L | L | $X$ | $O_{0}$ |
| $H$ | $X$ | $X$ | $Z$ |

$H=$ HIGH Voltage
L = LOW Voltage
$Z=$ High Impedance
$X=$ Immaterial
$\mathrm{O}_{0}=$ Previous $\mathrm{O}_{0}$ before HIGH -to-LOW transition of Latch Enable

## Logic Diagram

TL/F/10672-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

## Recommended Operating

## 54FCT/74FCT574 <br> Octal D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT574 is a high-speed, low power octal flip-flop with a buffered common Clock (CP) and a buffered common Output Enable ( $\overline{\mathrm{OE}}$ ). The information presented to the D inputs is stored in the flip-flops on the LOW-to-HIGH Clock (CP) transition.
FACT FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

The 'FCT574 is functionally identical to the 'FCT374 except for the pinouts.

## Features

■ NSC 54FCT/74FCT574 is pin and functionally equivalent to IDT 54FCT/74FCT574
■ Controlled output edge rates and undershoot for improved noise immunity. Internal split ground for improved noise immunity.

- Input clamp diodes to limit bus reflections.
- TTL/CMOS input and output level compatible.

■ $\mathrm{IOL}^{-1} 48 \mathrm{~mA}$ (Com) and 32 mA (Mil)

- CMOS power levels
- ESD immunity $\geq 4 \mathrm{kV}$ typ
- Military Product compliant to MIL-STD 883

Ordering Code: See Section 8

IEEE/IEC

TL/F/10673-4

TL/F/10673-3

## Functional Description

The 'FCT574 consists of eight edge-triggered flip-flops with individual D-type inputs and TRI-STATE true outputs. The buffered clock and buffered Output Enable are common to all flip-flops. The eight flip-flops will store the state of their individual $D$ inputs that meet the setup and hold time requirements on the LOW-to-HIGH Clock (CP) transition. With the Output Enable ( $\overline{\mathrm{OE}}$ ) LOW, the contents of the eight flipflops are available at the outputs. When $\overline{O E}$ is HIGH, the outputs go to the high impedance state. Operation of the $\overline{O E}$ input does not affect the state of the flip-flops.

Function Table

| Inputs |  |  | Internal | Outputs | Function |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\overline{\text { OE }}$ | CP | D | Q | $\mathrm{O}_{\mathrm{N}}$ |  |
| H | H | L | NC | Z | Hold |
| H | H | H | NC | Z | Hold |
| H | $\checkmark$ | L | L | Z | Load |

COUT for 74FCT only.

## 54FCT/74FCT646

## Octal Transceiver/Register with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT646 consist of registered bus transceiver circuits, with outputs, D-type flip-flops and control circuitry providing multiplexed transmission of data directly from the input bus or from the internal storage registers. Data on the A or B bus will be loaded into the respective registers on the LOW-to-HIGH transition of the appropriate clock pin (CPAB or CPBA).
FACTTM FCT utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCT features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

## Features

■ NSC 54FCT/74FCT646 is pin and functionally equivalent to IDT 54FCT/74FCT646

- Independent registers for $A$ and $B$ buses multiplexed real time and stored time
- Input clamp diodes to limit bus reflections

■ TTL/CMOS input and output level compatible

- $\mathrm{l}_{\mathrm{OL}}=64 \mathrm{~mA}$ (Com), 48 mA (Mil)
- CMOS power levels
- 4 kV minimum ESD immunity
- Military product compliant to MIL-STD-883

## 54FCT/74FCT138A <br> 1-of-8 Decoder/Demultiplexer

## General Description

The 'FCT138A is a high-speed 1 -of-8 decoder/demultiplexer. This device is ideally suited for high-speed bipolar memory chip select address decoding. The multiple input enables allow parallel expansion to a 1-of-24 decoder using just three 'FCT138A devices or a 1 -of-32 decoder using four 'FCT138A devices and one inverter.
FACTTM FCTA utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCTA features undershoot correction and split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT138A is pin and functionally equivalent to IDT 54FCT/74FCT138A
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{l}_{\mathrm{OL}}=48 \mathrm{~mA}$ (Com), 32 mA (Mil)
- CMOS power levels
- 4 kV minimum ESD immunity

■ Military Product compliant to MIL-STD 883

## Logic Symbol

TL/F/10658-3

| Pin Names | Description |
| :--- | :--- |
| $\mathrm{A}_{0}-\mathrm{A}_{2}$ | Address Inputs |

| $\mathrm{E}_{3}$ | Enable Input |
| $\overline{\mathrm{O}}_{0}-\overline{\mathrm{O}}_{7}$ | Outputs |

## 54FCT/74FCT240A

## Octal Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT240A is an inverting octal buffer and line driver designed to be employed as a memory address driver, clock driver and bus oriented transmitter or receiver which provides improved PC board density.

## Features

- NSC 54/74FCT240A is pin and functionally equivalent to IDT 54/74FCT240A
- Inverting TRI-STATE outputs drive bus lines or buffer memory address registers

## Ordering Code: See Section 8

## Logic Symbol

TL/F/10268-1

## Connection Diagrams

Pin Assignment for DIP, Flatpak and SOIC

TL/F/10268-2

- TTL input and output level compatible
- TTL inputs accept CMOS levels
- High current latch up immunity

■ $\mathrm{lol}^{2}=64 \mathrm{~mA}$ (commercial) and 48 mA (military)

- Electrostatic discharge protection $\geq 2 \mathrm{kV}$
- Military product compliant to MIL-STD 883C
- Inherently radiation tolerant

TL/F/10268-3

## 54FCT/74FCT241A

## Octal Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT241A is an octal buffer and line driver designed to be employed as a memory address driver, clock driver and bus-oriented transmitter or receiver which provides improved PC board density.

## Features

- NSC 54/74FCT241A is pin and functionally equivalent to IDT 54/74FCT241A
- Non-inverting TRI-STATE outputs drive bus lines or buffer memory address registers
- 'FCT241A has TTL-compatible inputs
- Military product compliant to MIL-STD-883C
- Inherently radiation tolerant
- $\mathrm{lOL}_{\mathrm{OL}}=64 \mathrm{~mA}$ (Comm) and 48 mA (Mil)
- TTL input and output level compatible
- High current latch up

Ordering Code: See Section 8
Logic Symbol

## 54FCT/74FCT244A <br> Octal Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT244A is an octal buffer and line driver designed to be employed as a memory address driver, clock driver and bus-oriented transmitter/receiver which provides improved PC board density.

## Features

- NSC 54/74FCT244A is pin and functionally equivalent to IDT 54/74FCT244A
- TRI-STATE outputs drive lines or buffer memory address registers
■ TTL input and output level compatible
- TTL inputs accept CMOS levels
- High current latch up immunity
( $\mathrm{IOL}=64 \mathrm{~mA}$ (commercial) and 48 mA (military)
- Electrostatic discharge protection $\geq 2 \mathrm{kV}$
m Military product compliant to MIL-STD 883C
- Inherently radiation tolerant

## Ordering Code: See Section 8

## Logic Symbol

## 54FCT/74FCT245A <br> Octal Bidirectional Transceiver with TRI-STATE ${ }^{\circledR}$ Inputs/Outputs

## General Description

The 'FCT245A contains eight non-inverting bidirectional buffers with TRI-STATE outputs and is intended for bus-oriented applications. The Transmit/Receive (T/ $\bar{R}$ ) input determines the direction of data flow through 'he bidirectional transceiver. Transmit (active-HIGH) enables data from A ports to B ports; Receive (active-LOW) enables data from B ports to A ports. The Output Enable input, when HIGH, disables both A and B ports by placing them in a HIGH Z condition.

## Features

- NSC 54/74FCT245A is pin and functionally equivalent to IDT 54/74FCT245A
- Non-inverting buffers
- Bidirectional data path
- TTL input and output level compatible

■ TTL inputs accept CMOS levels

- High current latch up immunity
- $\mathrm{IOL}=64 \mathrm{~mA}$ (commercial) and 48 mA (military)
- Electrostatic discharge protection $\geq 2 \mathrm{kV}$
- Military product compliant to MIL-STD 883C
- Inherently radiation tolerant

Ordering Code: See Section 8

## Logic Symbols

National Semiconductor

54FCT/74FCT273A Octal D Flip-Flop

## General Description

The 'FCT273A has eight edge-triggered D-type flip-flops with individual D inputs and Q outputs. The common buffered Clock (CP) and Master Reset (MR) input load and reset (clear) all flip-flops simultaneously.
The register is fully edge-triggered. The state of each $D$ input, one setup time before the LOW-to-HIGH clock transition, is transferred to the corresponding flip-flop's Q output.
All outputs will be forced LOW independently of Clock or Data inputs by a LOW voltage level on the $\overline{M R}$ input. The device is useful for applications where the true output only is required and the Clock and Master Reset are common to all storage elements.
FACTTM FCTA utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCTA features NSC correction and split ground bus for superior performance.

## ADVANCE INFORMATION

## Features

■ NSC 54FCT/74FCT273A is pin and functionally equivalent to IDT 54FCT/74FCT273A
■ Ideal buffer for MOS microprocessor or memory

- Buffered common clock

■ Buffered, asynchronous master reset

- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{lOL}_{\mathrm{OL}}=48 \mathrm{~mA}$ (Com), 32 mA (Mil)
- CMOS power levels
- 4 kV minimum ESD immunity
- Military Product compliant to MIL-STD 883

## Logic Symbols

| Pin Names | Description |
| :--- | :--- |
| $\frac{D_{0}-D_{7}}{M R}$ | Data Inputs |
| $C P$ | Master Reset |

## 54FCT/74FCT373A

## Octal Transparent Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT373A consists of eight latches with TRI-STATE outputs for bus organized system applications. The flip-flops appear transparent to the data when Latch Enable (LE) is HIGH. When LE is LOW, the data that meets the setup time is latched. Data appears on the bus when the Output Enable ( $\overline{\mathrm{OE}}$ ) is LOW. When $\overline{\mathrm{OE}}$ is HIGH, the bus output is in the high impedance state.

## Features

- NSC 54/74FCT373A pin and functionally equivalent to IDT 54/74FCT373A
- Eight latches in a single package
- TRI-STATE outputs for bus interfacing
- TTL input and output level compatible
- High current latch up immunity
- $\mathrm{l}_{\mathrm{OL}}=48 \mathrm{~mA}$ (commercial) and 32 mA (military)

■ Military product compliant to MIL-STD 883

Ordering Code: See Section 8

## Logic Symbols

## Connection Diagrams

Pin Assignment for DIP, Flatpak and SOIC

Pin Assignment for LCC

TL/F/10618-4

## Functional Description

The 'FCT373A contains eight D-type latches with TRISTATE outputs. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent, i.e., a latch output will change state each time its D input changes. When LE is LOW, the latches store the information that was present on the D inputs a setup time preceding the HIGH-to-LOW transition of LE. The TRI-STATE outputs are controlled by the Output Enable ( $\overline{\mathrm{OE}}$ ) input. When $\overline{\mathrm{OE}}$ is LOW, the standard outputs are in the 2 -state mode. When $\overline{\mathrm{OE}}$ is HIGH, the standard outputs are in the high impedance mode but this does not interfere with entering new data into the latches.

## Truth Table

| Inputs |  |  | Outputs |
| :---: | :---: | :---: | :---: |

## DC Characteristics for 'FCTA Family Devices (Continued)

Typical values are at $\mathrm{V}_{\mathrm{CC}}=5.0 \mathrm{~V}, 25^{\circ} \mathrm{C}$ ambient and maximum loading. For test conditions shown as Max, use the value specified for the appropriate device type: Com: $\mathrm{V}_{\mathrm{CC}}=5.0 \mathrm{~V} \pm 5 \%, \mathrm{~T}_{\mathrm{A}}=0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$; Mil: $\mathrm{V}_{\mathrm{CC}}=5.0 \mathrm{~V} \pm 10 \%, \mathrm{~T}_{\mathrm{A}}=-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}, \mathrm{V}_{\mathrm{HC}}=\mathrm{V}_{\mathrm{CC}}-0.2 \mathrm{~V}$

## 54FCT/74FCT374A <br> Octal D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT374A is a high-speed, low-power octal D-type flipflop featuring separate D-type inputs for each flip-flop and TRI-STATE outputs for bus-oriented applications. A buffered Clock (CP) and Output Enable ( $\overline{\mathrm{OE}}$ ) are common to all flip-flops.

## Features

- NSC 54/74FCT374A is pin and functionally equivalent to IDT 54/74FCT374A
- Buffered positive edge triggered clock
- TRI-STATE outputs for bus-oriented applications
- TTL input and output level compatible
- TTL inputs accept CMOS levels
- High current latch up immunity
- $\mathrm{l}_{\mathrm{OL}}=48 \mathrm{~mA}$ (commercial) and 32 mA (military)
- Electrostatic discharge protection $\geq 2 \mathrm{kV}$
- Inherently radiation tolerant

Ordering Code: See Section 8

## Functional Description

The 'FCT374A consists of eight edge-triggered flip-flops with individual D-type inputs and TRI-STATE outputs. The buffered clock and buffered Output Enable are common to all flip-flops. The eight flip-flops will store the state of their individual $D$ inputs that meet the setup and hold time requirements on the LOW-to-HIGH Clock (CP) transition. With the Output Enable ( $\overline{\mathrm{OE}}$ ) LOW, the contents of the eight flipflops are available at the outputs. When the $\overline{\mathrm{OE}}$ is HIGH, the outputs go to the high impedance state. Operation of the $\overline{\mathrm{OE}}$ input does not affect the state of the flip-flops.

## Truth Table

## 54FCT377A/74FCT377A Octal D Flip-Flop with Clock Enable

## General Description

The FCT377A has eight edge-triggered, D-type flip-flops with individual $D$ inputs and $Q$ outputs. The common buffered Clock (CP) input loads all flip-flops simultaneously, when the Clock Enable ( $\overline{\mathrm{CE}}$ ) is LOW.
The register is fully edge-triggered. The state of each $D$ input, one setup time before the LOW-to-HIGH clock transition, is transferred to the corresponding flip-flop's Q output. The $\overline{\mathrm{CE}}$ input must be stable only one setup time prior to the LOW-to-HIGH clock transition for predictable operation.
FACTTM FCTA utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCTA features undershoot corrector in addition to a split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT377A is pin and functionally equivalent to IDT 54FCT/74FCT377A
- Ideal for addressable register applications
- Clock enables for address and data synchronization applications
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
- $\mathrm{lOL}^{2}=48 \mathrm{~mA}$ (com), 32 mA (mil)
- CMOS power levels
- ESD immunity $\geq 4 \mathrm{kV}$.
- Military product compliant to MIL-STD 883

## 54FCT/74FCT521A <br> 8-Bit Identity Comparator

## General Description

The 'FCT521A is an expandable 8-bit comparator. It compares two words of up to eight bits each and provides a LOW output when the two words match bit for bit. The expansion input $\bar{I}_{\mathrm{A}}=\mathrm{B}$ also serves as an active LOW enable input.
FACTTM FCTA utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.

FACT FCTA features undershoot correction and split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT521A is pin and functionally equivalent to IDT 54FCT/74FCT521A

## 54FCT/74FCT533A

## Octal Transparent Latch with TRI-STATE® Outputs

## General Description

The 'FCT533A consists of eight latches with TRI-STATE outputs for bus organized system applications. The flip-flops appear transparent to the data when Latch Enable (LE) is HIGH. When LE is LOW, the data that meets the setup times is latched. Data appears on the bus when the Output Enable ( $\overline{\mathrm{OE})}$ is LOW. When OE is HIGH the bus output is in the high impedance state. The 'FCT533A is the same as the 'FCT373A, except that the outputs are inverted.
FACT FCTA utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.

FACT FCTA features undershoot correction and split ground bus for superior performance.

Pin Assignment for DIP, SOIC and Flatpak

TL/F/10638-2

Pin Assignment for LCC

TL/F/10638-3

| Pin Names | Description |
| :--- | :--- |
| $\mathrm{D}_{0}-\mathrm{D}_{7}$ | Data Inputs |
| LE | Latch Enable Input (Active HIGH) |
| $\overline{\mathrm{OE}}$ | Output Enable Input (Active LOW) |
| $\overline{\mathrm{O}}_{0}-\overline{\mathrm{O}}_{7}$ | Complementary TRI-STATE Outputs |

the D inputs a setup time preceding the HIGH-to-LOW transition of LE. The TRI-STATE buffers are controlled by the Output Enable ( $\overline{\mathrm{OE}}$ ) input. When $\overline{O E}$ is LOW the latch contents are presented inverted at the outupts $\overline{\mathrm{O}}_{7}-\overline{\mathrm{O}}_{0}$. When $\overline{\mathrm{OE}}$ is HIGH the buffers are in the high impedance mode but this does not interfere with entering new data into the latches.

| Inputs |  |  | Output |
| :---: | :---: | :---: | :---: |
| LE | $\overline{\mathbf{O E}}$ | $\mathbf{D}$ | $\overline{\mathbf{O}}$ |
| $H$ | L | H | L |

| X | H | X | Z |

$H=$ HIGH Voltage Level
L = LOW Voltage Level
$X=\operatorname{Logic}(0)$ or logic(1) must be valid Input Level
Function Table

## Functional Description

The 'FCT533A contains eight D-type latches with TRISTATE output buffers. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent and the latch output will change state each time its $D$ input changes. When LE is LOW, the latches store the information that was present on

## Logic Diagram

TL/F/10638-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

## 54FCT/74FCT534A

## Octal D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT534A is a high-speed, low-power octal D-type flipflop featuring separate D-type inputs for each flip-flop and TRI-STATE outputs for bus-oriented applications. A buffered Clock (CP) and Output Enable ( $\overline{\mathrm{OE}}$ ) are common to all flip-flops. The 'FCT534A is the same as the 'FCT374A except that the outputs are inverted.

## Features

- NSC 54/74FCT534A is pin and functionally equivalent to IDT 54/74FCT534A
- Edge-triggered D-type inputs
- Buffered positive edge-triggered clock
- TTL input and output level compatible
- TTL inputs accept CMOS levels
- High current latch up
- $\mathrm{loL}^{\prime}=48 \mathrm{~mA}$ (Com), 32 mA (Mil)

■ Military product compliant to MIL-STD-883

Ordering Code: See Section 8

| $\overline{O E}$ | TRI-STATE Output Enable Input |
| $\overline{\mathrm{O}}_{0}-\bar{O}_{7}$ | Complementary TRI-STATE Outputs |

TL/F/10619~4

## Functional Description

The 'FCT534A consists of eight edge-triggered flip-flops with individual D-type inputs and TRI-STATE complementary outputs. The buffered clock and buffered Output Enable are common to all flip-flops. The eight flip-flops will store the state of their individual $D$ inputs that meet the setup and hold times requirements on the LOW-to-HIGH Clock (CP)
transition. With the Output Enable (OE) LOW, the contents of the eight flip-flops are available at the outputs. When the $\overline{\mathrm{OE}}$ is HIGH, the outputs go to the high impedance state. Operation of the OE input does not affect the state of the flip-flops.

## 54FCT/74FCT543A Octal Registered Transceiver

## General Description

The FCT543A octal transceiver contains two sets of D-type latches for temporary storage of data flowing in either direction. Separate Latch Enable and Output Enable inputs are provided for each register to permit independent control of inputting and outputting in either direction of data flow.
FACTTM FCTA utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCTA features undershoot correction and split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT543A is pin and functionally equivalent to IDT 54FCT/74FCT543A
■ Speed controls for data flow in each direction
- Back to back latched transceiver

⿴囗 Input clamp diodes to limit bus reflections

- TTL/CMOS input and output level compatible
m $\mathrm{I}_{\mathrm{OL}}=64 \mathrm{~mA}$ (com), 48 mA (mil)
- CMOS power levels
- 4 kV minimum ESD immunity
- Military product complaint to MIL-STD 883

Ordering Code: See Section 8

| $\mathrm{B}_{0}-\mathrm{B}_{7}$ | B-to-A Data Inputs or |
|  | A-to-B TRI-STATE Outputs |

## Functional Description

The FCT543A contains two sets of eight D-type latches, with separate input and output controls for each set. For data flow from $A$ to $B$, for example, the $A$-to- $B$ Enable ( $\overline{C E A B}$ ) input must be LOW in order to enter data from $A_{0}-$ $A_{7}$ or take data from $B_{0}-B_{7}$, as indicated in the Data I/O Control Table. With $\overline{C E A B}$ LOW, a LOW signal on the A-to-B Latch Enable ( $\overline{L E A B}$ ) input makes the A-to-B latches transparent; a subsequent LOW-to-HIGH transition of the LEAB signal puts the $A$ latches in the storage mode and their outputs no longer change with the $A$ inputs. With CEAB and $\overline{O E A B}$ both LOW, the TRI-STATE B output buffers are active and reflect the data present at the output of the A latches. Control of data flow from $B$ to $A$ is similar, but using the $\overline{C E B A}, \overline{L E B A}$ and $\overline{O E B A}$ inputs.

Data I/O Control Table

## 54FCT/74FCT544A

## Octal Registered Transceiver

## General Description

The 'FCT544A octal transceiver contains two sets of D-type latches for temporary storage of data flowing in either direction. Separate Latch Enable and Output Enable inputs are provided for each register to permit independent control of inputting and outputting in either direction of data flow. The 'FCT544A inverts data in both directions.
FACTTM FCTA utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCTA features undershoot correction and split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT544A is pin and functionally equivalent to IDT 54FCT/74FCT544A
- Back to back registers for storage separate controls for data flow in each direction
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible
$\mathrm{l}_{\mathrm{OL}}=64 \mathrm{~mA}$ (Com), 48 mA (Mil)
- CMOS power levels
- 4 kV minimum ESD immunity
- Military Product compliant to MIL-STD 883

## Ordering Code: See Section 8

| $\overline{\mathrm{B}}_{0}-\overline{\mathrm{B}}_{7}$ | B-to-A Data Inputs or A-to-B |
|  | TRI-STATE Outputs |

TL/F/10669-4

## Functional Description

The 'FCT544A contains two sets of eight D-type latches, with separate input and output controls for each set. For data flow from $A$ to $B$, for example, the $A-t o-B$ Enable ( $\overline{\mathrm{CEAB}}$ ) input must be LOW in order to enter data from $\overline{\mathrm{A}}_{0}-$ $\overline{\mathrm{A}}_{7}$ or take data from $\overline{\mathrm{B}}_{0}-\overline{\mathrm{B}}_{7}$, as indicated in the Data 1/O Control Table. With CEAB LOW, a LOW signal on the A-to-B Latch Enable ( $\overline{\mathrm{LEAB}}$ ) input makes the A-to-B latches transparent; a subsequent LOW-to-HIGH transition of the LEAB signal puts the $A$ latches in the storage mode and their outputs no longer change with the $A$ inputs. With $\overline{C E A B}$ and $\overline{O E A B}$ both LOW, the TRI-STATE B output buffers are active and reflect the data present at the output of the A latches. Control of data flow from $B$ to $A$ is similar, but using the $\overline{C E B A}, \overline{L E B A}$ and $\overline{O E B A}$ outputs.

|  | Input |  | Latch | Output |
| :---: | :---: | :---: | :---: | :---: |

## 54FCT/74FCT563A Octal Latch with TRI-STATE ${ }^{\circledR}$ <br> Outputs

## General Description

The 'FCT563A is a high-speed octal latch with buffered common Latch Enable (LE) and buffered common Output Enable ( $\overline{O E}$ ) inputs.
The 'FCT563A device is functionally identical to the 'FCT573A, but with inverted outputs.

FACTTM FCTA utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCTA features undershoot correction and split ground bus for superior performance.

## Features

- Inputs and outputs on opposite side of package allow easy interface with microprocessors
- Useful as input or output port for microprocessors
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible

■ $\mathrm{lOL}_{\mathrm{OL}}=48 \mathrm{~mA}(\mathrm{Com}), 32 \mathrm{~mA}$ (Mil)

- CMOS power levels
- 4 kV minimum ESD immunity
- Military product compliant to MIL-STD-883
- Inherently radiation tolerant

## Ordering Code: See Section 8

TL/F/10639-4

Functional Description
The 'FCT563A contains eight D-type latches with TRISTATE complementary outputs. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent, i.e., a latch output will change state each time its $D$ input changes. When LE is LOW the latches store the information that was present on the D inputs a setup time preceding the HIGH-toLOW transition of LE. The TRI-STATE buffers are controlled by the Output Enable ( $\overline{O E}$ ) input. When $\overline{O E}$ is LOW, the buffers are in the TRI-STATE mode. When OE is HIGH the buffers are in the high impedance mode but that does not interfere with entering new data into the latches.

Function Table

| Inputs |  |  |  | Outputs |
| :---: | :---: | :---: | :---: | :--- |
| Function |  |  |  |  |
|  | LE | D | $\mathbf{O}$ |  |
| H | X | X | Z | High-Z |
| L | H | L | H | Transparent |
| L | H | H | L | Transparent |
| L | L | X | NC | Latched |

H = HIGH Voltage Level
L = LOW Voltage Level
$X=$ Immaterial
$Z=$ High Impedance
$N C=$ No Change

## Logic Diagram

Absolute Maximum Ratings (Note 1)
If Milltary/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Terminal Voltage with Respect to GND (VTERM)

| 54FCTA | -0.5 V to +7.0 V |
| :--- | ---: |
| 74FCTA | -0.5 V to +7.0 V |
| Temperature under Bias (T ${ }_{\text {BIAS }}$ ) |  |
| 74FCTA | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| 54FCTA | $-65^{\circ} \mathrm{C}$ to $+135^{\circ} \mathrm{C}$ |
| Storage Temperature (TSTG) |  |
| 74FCTA | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| 54FCTA | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Power Dissipation (PT) | 0.5 W |
| DC Output Current (louT) | 120 mA |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACTTM circuits outside databook specifications.

## 54FCT/74FCT564A

## Octal D Flip-FIop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT564A is a high-speed, low power octal flip-flop with a buffered common Clock (CP) and a buffered common Output Enable ( $\overline{\mathrm{OE}}$ ). The information presented to the $D$ inputs is stored in the flip-flops on the LOW-to-HIGH Clock (CP) transition.

The 'FCT564A device is functionally identical to the 'FCT574A, but with inverted outputs.
FACTTM FCTA utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.

FACT FCTA features undershoot correction and split ground bus for superior performance.

## Features

- TRI-STATE outputs for bus-oriented applications
- Useful as input or output port for microprocessors
- Input clamp diodes to limit bus reflections
- TTL/CMOS input and output level compatible

■ $\mathrm{lOL}^{2}=48 \mathrm{~mA}$ (Com), 32 mA (Mil)

- CMOS power levels

■ 4 kV minimum ESD immunity

- Military product compliant to MIL-STD-883
- Inherently radiation tolerant

Ordering Code: See Section 8

## 54FCT/74FCT573A <br> Octal Latch with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT573A is a high-speed octal latch with buffered common Latch Enable (LE) and buffered common Output Enable ( $\overline{\mathrm{OE}}$ ) inputs.

The 'FCT573A is functionally identical to the 'FCT373A but has inputs and outputs on opposite sides.

## Features

- NSC 54/74FCT573A is pin and functionally equivalent to IDT 54/74FCT573A
- Inputs and outputs on opposite sides of package allowing easy interface with microprocessors
- Useful as input or output port for microprocessors
- $\mathrm{IOL}=48 \mathrm{~mA}$ (Com), 32 mA (Mil)
- TRI-STATE outputs for bus interfacing
- Military product compliant to MIL-STD-883
- TTL input and output level compatible
- TTL inputs accept CMOS levels

Ordering Code: See Section 8

## Logic Symbols

## Connection Diagrams

Pin Assignment for DIP, Flatpak and SOIC

Pin Assignment for LCC

TL/F/10641-4

## Functional Description

The FCT573A contains eight D-type latches with TRISTATE output buffers. When the Latch Enable (LE) input is HIGH, data on the $D_{n}$ inputs enters the latches. In this condition the latches are transparent, and the latch output will change state each time its $D$ input changes. When LE is LOW the latches store the information that was present on the D inputs a setup time preceding the HIGH-to-LOW transition of LE. The TRI-STATE buffers are controlled by the Output Enable ( $\overline{\mathrm{OE}})$ input. When $\overline{\mathrm{OE}}$ is LOW, the latch contents are presented inverted at the outputs $\overline{\mathrm{O}}_{7}-\overline{\mathrm{O}}_{0}$. When $\overline{\mathrm{OE}}$ is HIGH the buffers are in the high impedance mode but this does not interfere with entering new data into the latches.

Truth Table

| Inputs |  |  | Outputs |
| :---: | :---: | :---: | :---: |
| $\overline{O E}$ | LE | $\mathbf{D}$ | $\mathbf{O}_{\boldsymbol{n}}$ |

## 54FCT/74FCT574A

## Octal D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT574A is a high-speed, low power octal flip-flop with a buffered common Clock (CP) and a buffered common Output Enable ( $\overline{\mathrm{OE}}$ ). The information presented to the D inputs is stored in the flip-flops on the LOW-to-HIGH Clock (CP) transition.
The 'FCT574A is functionally identical to the 'FCT374A except for the pinouts.

## Features

- NSC 54/74FCT574A is pin and functionally equivalent to IDT54/74FCT574A
- Inputs and outputs on opposite sides of package allowing easy interface with microprocessors
- Useful as input or output port for microprocessors
- Functionally identical to 'FCT374A

■ TRI-STATE outputs for bus-oriented applications
■ 'FCT574A has TTL-compatible inputs

- $\mathrm{loL}=48 \mathrm{~mA}$ (Comm) and 32 mA (Mil)
- TTL inputs accept CMOS levels

Ordering Code: See Section 8

Logic Symbols

Pin Assignment for DIP, Flatpak and SOIC

## Connection Diagrams

## Functional Description

The 'FCT574A consists of eight edge-triggered flip-flops with individual D-type inputs and TRI-STATE true outputs. The buffered clock and buffered Output Enable are common to all flip-flops. The eight flip-flops will store the state of their individual D inputs that meet the setup and hold time requirements on the LOW-to-HIGH Clock (CP) transition. With the Output Enable ( $\overline{O E}$ ) LOW, the contents of the eight flip-flops are available at the outputs. When OE is HIGH, the outputs go to the high impedance state. Operation of the $\overline{\mathrm{OE}}$ input does not affect the state of the flip-flops.

Function Table

## Logic Diagram

TL/F/10150-5
Please note that this diagram is provided only for the understanding of logic operations and should not be used to estimate propagation delays.

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specifled devices are required,
please contact the National Semiconductor Sales
Office/Distributors for availability and specifications.
Terminal Voltage with Respect to GND (V TERM)
54FCTA
74FCTA
Temperature under Bias (TBIAS)
74FCTA
54FCTA
Storage Temperature (TSTG)
74FCTA
54FCTA
Power Dissipation (PT)
DC Output Current (louT)
Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables. National does not recommend operation of FACT FCT circuits outside databook specifications.

Recommended Operating Conditions
Supply Voltage $\left(V_{C C}\right)$
$54 F C T A$ 4.5 V to 5.5 V 74FCTA
Input Voltage
Output Voltage
Operating Temperature $\left(T_{A}\right)$ 54 FCTA $\quad-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ 74FCTA $\quad 0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$
Junction Temperature ( $\mathrm{T}_{\mathrm{J}}$ )
CDIP
$175^{\circ} \mathrm{C}$
PDIP
$140^{\circ} \mathrm{C}$

## DC Characteristics for 'FCTA Family Devices

Typical values are at $\mathrm{V}_{\mathrm{CC}}=5.0 \mathrm{~V}, 25^{\circ} \mathrm{C}$ ambient and maximum loading. For test conditions shown as Max, use the value specified for the appropriate device type: Com: $\mathrm{V}_{\mathrm{CC}}=5.0 \mathrm{~V} \pm 5 \%, \mathrm{~T}_{\mathrm{A}}=0^{\circ} \mathrm{C}$ to $+70^{\circ} \mathrm{C}$; Mil: $\mathrm{V}_{\mathrm{CC}}=5.0 \mathrm{~V} \pm 10 \%, \mathrm{~T}_{\mathrm{A}}=-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}, \mathrm{V}_{\mathrm{HC}}=\mathrm{V}_{\mathrm{CC}}-0.2 \mathrm{~V}$

## ADVANCE INFORMATION

## 54FCT／74FCT646A <br> Octal Transceiver／Register with TRI－STATE® Outputs

## General Description

The FCT646A consist of registered bus transceiver circuits， with outputs，D－type flip－flops and control circuitry providing multiplexed transmission of data directly from the input bus or from the internal storage registers．Data on the A or B bus will be loaded into the respective registers on the LOW－ to－HIGH transition of the appropriate clock pin（CPAB or CPBA）．
FACTTM FCTA utilizes NSC quiet series technology to pro－ vide improved quiet output switching and dynamic threshold performance．
FACT FCTA features undershoot correction and split ground bus for superior performance．

## Features

■ NSC 54FCT／74FCT646A is pin and functionally equiva－ lent to IDT 54FCT／74FCT646A
－Independent registers for $A$ and $B$ buses
－Multiplexed real－time and stored data transfers
－Input clamp diodes to limit bus reflections
－TTL／CMOS input and output level compatible
■ $\mathrm{IOL}^{-1} 64 \mathrm{~mA}$（Com）， 48 mA （Mil）
－CMOS power levels
－ 4 kV minimum ESD immunity
－Military Product compliant to MIL－STD 883

## 54FCT/74FCT821A • 54FCT/74FCT821B 10-Bit D Flip-Flop with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT821A/B is a 10 -bit D flip-flop with TRI-STATE oututs arranged in a broadside pinout.
FACTTM FCTA/B utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCTA features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

FACT FCTB features an undershoot corrector in addition to a split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT821A/B is pin and functionally equivalent to IDT 54FCT/74FCT821A/B
- High-speed parallel registers with positive edge-triggered D-type flip-flops for ringing suppression
- Buffered common clock enable (EN) and asynchronous clear input (CLR)
- Input clamp diodes for ringing suppression
- TTL/CMOS input and output level compatible
- $\mathrm{l}_{\mathrm{OL}}=48 \mathrm{~mA}(\mathrm{COM}), 32 \mathrm{~mA}$ (MIL)
- CMOS power levels
- 4 kV minimum ESD immunity
- Military Product compliant to MIL-STD 883
- TRI-STATE outputs for bus interfacing
- Noninverting outputs

## 54FCT/74FCT823A • 54FCT/74FCT823B 9-Bit D Flip-Flop

## General Description

The 'FCT823A/B is a 9 -bit buffered register. It features Clock Enable and Clear which are ideal for parity bus interfacing in high performance microprogramming systems. FACTTM FCTA/B utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCTA features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.
FACT FCTB features an undershoot corrector in addition to a split ground bus for superior performance.

## Features

NSC 54FCT/74FCT823A/B is pin and functionally equivalent to IDT 54FCT/74ACT823A/B
■ High speed parallel registers with positive edge-triggered D-type flip-flop
(1) Buffered common clock enable ( $\overline{\mathrm{EN}}$ ) and asynchronous clear input (CLR)
(wnput clamp diodes to limit bus reflections
(TTL/CMOS input and output level compatible

## 54FCT/74FCT825A - 54FCT/74FCT825B 8-Bit D Flip-Flop

## General Description

The 'FCT825A/B is an 8 -bit buffered register. They have Clock Enable and Clear features which are ideal for parity bus interfacing in high performance microprogramming systems. Also included are multiple enables that allow multiuse control of the interface.

FACTTM FCTA/B utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCTA features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

FACT FCTB features an undershoot corrector in addition to a split ground bus for superior performance.

## 54FCT/74FCT827A • 54FCT/74FCT827B 10-Bit Buffer/Line Driver with TRI-STATE ${ }^{\circledR}$ Outputs

## General Description

The 'FCT827A/B 10-bit bus buffer provides high performance bus interface buffering for wide data/address paths or buses carrying parity. The 10 -bit buffers have NOR output enables for maximum control flexibility.
FACTTM FCTA/B utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCTA features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.

FACT FCTB features an undershoot corrector in addition to a split ground bus for superior performance.

## Features

## 54FCT/74FCT843A • 54FCT/74FCT843B 9-Bit Transparent Latch

## General Description

The 'FCT843A/B bus interface latch is designed to eliminate the extra packages required to buffer existing latches and provide extra data width for wider address/data paths. FACTTM FCTA/B utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCTA features GTOTM output control and undershoot corrector in addition to a split ground bus for superior performance.
FACT FCTB features an undershoot corrector in addition to a split ground bus for superior performance.

## Features

- NSC 54FCT/74FCT843A/B is pin and functionally equivalent to IDT 54FCT/74FCT843A/B
- High Speed parallel latches
- Buffered common latch enable, clear and preset inputs

## 54FCT/74FCT899A

## 9-Bit Latchable Transceiver with Parity Generator/Checker

## General Description

The 'FCT899A is a 9-bit to 9-bit parity transceiver with transparent latches. The device can operate as a feed-through transceiver or it can generate/check parity from the 8-bit data busses in either direction. It has a guaranteed current sinking capability of 24 mA at the A-bus and 64 mA at the B-bus.

The 'FCT899A features independent latch enables for the A-to-B direction and the B-to-A direction, a select pin for ODD/EVEN parity, and separate error signal output pins for checking parity.
FACTTM FCTA utilizes NSC quiet series technology to provide improved quiet output switching and dynamic threshold performance.
FACT FCTA features undershoot correction and split ground bus for superior performance.

## Ordering Code: See Section 8

## Logic Symbol

## Features

- Latchable transceiver with output sink of 24 mA at the A-bus and 64 mA at the B-bus

■ Option to select generate parity and check or "feedthrough'" data/parity in directions A-to-B or B-to-A

- Independent latch enables for $\mathrm{A}-\mathrm{to}-\mathrm{B}$ and B -to-A directions
- Select pin for ODD/EVEN parity
- ERRA and ERRB output pins for parity checking
- Ability to simultaneously generate and check parity
- CMOS power levels
- Guaranteed 4000 V min ESD protection

## Connection Diagram

| Pin Names | Description |
| :---: | :---: |
| $\mathrm{A}_{0}-\mathrm{A}_{7}$ | A Bus Data Inputs/Data Outputs |
| $\mathrm{B}_{0}-\mathrm{B}_{7}$ | B Bus Data Inputs/Data Outputs |
| APAR, BPAR | $A$ and B Bus Parity Inputs |
| ODD/EVEN | ODD/EVEN Parity Select, Active LOW for EVEN Parity |
| $\overline{\mathrm{GBA}}, \overline{\mathrm{GAB}}$ | Output Enables for A or B Bus, Active LOW |
| $\overline{\text { SEL }}$ | Select Pin for Feed-Through or Generate Mode, LOW for Generate Mode |
| LEA, LEB | Latch Enables for A and B Latches, HIGH for Transparent Mode |
| $\overline{\text { ERRA }}$, ERRB | Error Signals for Checking Generated Parity with Parity In, LOW if Error Occurs |

## Functional Description

The 'FCT899A has three principal modes of operation which are outlined below. These modes apply to both the A-to-B and $B$-to-A directions.

- Bus $A(B)$ communicates to Bus $B(A)$, parity is generated and passed on to the $B(A)$ Bus as BPAR (APAR). If LEB (LEA) is HIGH and the Mode Select (SEL) is LOW, the parity generated from $B[0: 7]$ ( $A[0: 7]$ ) can be checked and monitored by ERRB (ERRA).
- Bus $A(B)$ communicates to Bus $B(A)$ in a feed-through mode if SEL is HIGH. Parity is still generated and checked as ERRA and ERRB in the feed-through mode (can be used as an interrupt to signal a data/parity bit error to the CPU).
- Independent Latch Enables (LEA and LEB) allow other permutations of generating/checking (see Function Table below).

Function Table

| Inputs |  |  |  |  | Operation |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\overline{\text { GAB }}$ | $\overline{\text { GBA }}$ | SEL | LEA | LEB |  |
| H | H | X | X | X | Busses A and B are TRI-STATE ${ }^{\text {® }}$. |
| H | L | L | L | H | Generates parity from $B[0: 7]$ based on $O / \bar{E}$ (Note 1). Generated parity $\rightarrow$ APAR. Generated parity checked against BPAR and output as $\overrightarrow{\text { ERRB. }}$ |
| H | L | L | H | H | Generates parity from $\mathrm{B}[0: 7]$ based on $\mathrm{O} / \overline{\mathrm{E}}$. Generated parity $\rightarrow$ APAR. Generated parity checked against BPAR and output as ERRB. Generated parity also fed back through the A latch for generate/check as ERRA. |
| H | L | L | X | L | Generates parity from $B$ latch data based on $O / E$. Generated parity $\rightarrow$ APAR. Generated parity checked against latched BPAR and output as ERRB. |
| H | L | H | X | H | BPAR/B[0:7] $\rightarrow$ APAR/A0:7] Feed-through mode. Generated parity checked against BPAR and output as ERRB. |
| H | L | H | H | H | BPAR/B[0:7] $\rightarrow$ APAR/A[0:7] <br> Feed-through mode. Generated parity checked against BPAR and output as ERRB. Generated parity also fed back through the A latch for generate/check as ERRA. |
| L | H | L | H | L | Generates parity for $A[0: 7]$ based on $O / \bar{E}$. Generated parity $\rightarrow$ BPAR. Generated parity checked against APAR and output as ERRA. |
| L | H | L | H | H | Generates parity from $A[0: 7]$ based on $O / \bar{E}$. Generated parity $\rightarrow$ BPAR. Generated parity checked against APAR and output as ERRA. Generated parity also fed back through the B latch for generate/check as ERRB. |
| L | H | L | L | X | Generates parity from A latch data based on O/E. Generated parity $\rightarrow$ BPAR. Generated parity checked against latched APAR and output as ERRA. |
| L | H | H | H | L | APAR/A[0:7] $\rightarrow$ BPAR/B[0:7] <br> Feed-through mode. Generated parity checked against APAR and output as ERRA. |
| L | H | H | H | H | APAR/A[0:7] $\rightarrow$ BPAR/B[0:7] <br> Feed-through mode. Generated parity checked against APAR and output as ERRA. Generated parity also fed back through the B latch for generate/check as ERRB. |

Absolute Maximum Ratings (Note 1)
If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.
Terminal Voltage with Respect to GND (VTERM)

| 54FCTA | -0.5 V to +7.0 V |
| :--- | ---: |
| 74FCTA | -0.5 V to +7.0 V |
| Temperature under Bias (TBIAS) | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| 74FCTA | $-65^{\circ} \mathrm{C}$ to $+135^{\circ} \mathrm{C}$ |
| 54FCTA |  |
| Storage Temperature (TSTG) | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| 74FCTA | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| 54FCTA | 0.5 W |
| Power Dissipation (PT) | 120 mA |
| DC Output Current (louT) |  |

Note 1: Absolute maximum ratings are those values beyond which damage to the device may occur. Exposure to absolute maximum rating conditions for extended periods may affect reliability. The databook specifications should be met, without exception, to ensure that the system design is reliable over its power supply, temperature, and output/input loading variables.

## Bookshelf of Technical Support Information

National Semiconductor Corporation recognizes the need to keep you informed about the availability of current technical literature.

This bookshelf is a compilation of books that are currently available. The listing that follows shows the publication year and section contents for each book.

Please contact your local National sales office for possible complimentary copies. A listing of sales offices follows this bookshelf.
We are interested in your comments on our technical literature and your suggestions for improvement.
Please send them to:
Technical Communications Dept. M/S 16-300
2900 Semiconductor Drive

ALS/AS LOGIC DATABOOK—1990<br>Introduction to Advanced Bipolar Logic • Advanced Low Power Schottky • Advanced Schottky

# ASIC DESIGN MANUAL/GATE ARRAYS \& STANDARD CELLS—1987 

SSI/MSI Functions • Peripheral Functions • LSI/VLSI Functions • Design Guidelines • Packaging

## CMOS LOGIC DATABOOK—1988

CMOS AC Switching Test Circuits and Timing Waveforms • CMOS Application Notes • MM54HC/MM74HC MM54HCT/MM74HCT • CD4XXX • MM54CXXX/MM74CXXX • Surface Mount

## DATA ACQUISITION LINEAR DEVICES-1989

Active Filters • Analog Switches/Multiplexers • Analog-to-Digital Converters • Digital-to-Analog Converters Sample and Hold • Temperature Sensors • Voltage Regulators • Surface Mount

## DATA COMMUNICATION/LAN/UART DATABOOK—1990

LAN IEEE 802.3 • High Speed Serial/IBM Data Communications • ISDN Components • UARTs Modems • Transmission Line Drivers/Receivers

## DISCRETE SEMICONDUCTOR PRODUCTS DATABOOK—1989

Selection Guide and Cross Reference Guides • Diodes • Bipolar NPN Transistors Bipolar PNP Transistors • JFET Transistors • Surface Mount Products • Pro-Electron Series Consumer Series • Power Components • Transistor Datasheets • Process Characteristics

DRAM MANAGEMENT HANDBOOK—1989
Dynamic Memory Control • Error Detection and Correction • Microprocessor Applications for the DP8408A/09A/17/18/19/28/29 • Microprocessor Applications for the DP8420A/21A/22A
Microprocessor Applications for the NS32CG821

## EMBEDDED SYSTEM PROCESSOR DATABOOK—1989

Embedded System Processor Overview • Central Processing Units • Slave Processors • Peripherals Development Systems and Software Tools

## F100K ECL LOGIC DATABOOK \& DESIGN GUIDE-1990

Family Overview • 300 Series (Low-Power) Datasheets • 100 Series Datasheets • 11C Datasheets ECL BiCMOS SRAM, ECL PAL, and ECL ASIC Datasheets • Design Guide • Circuit Basics • Logic Design Transmission Line Concepts • System Considerations • Power Distribution and Thermal Considerations Testing Techniques • Quality Assurance and Reliability • Application Notes

FACTTM ADVANCED CMOS LOGIC DATABOOK—1990<br>Description and Family Characteristics • Ratings, Specifications and Waveforms<br>Design Considerations • 54AC/74ACXXX • 54ACT/74ACTXXX • Quiet Series: 54ACQ/74ACQXXX<br>Quiet Series: 54ACTQ/74ACTQXXX • 54FCT/74FCTXXX • FCTA: 54FCTXXXA/74FCTXXXA

FAST® ${ }^{\circledR}$ ADVANCED SCHOTTKY TTL LOGIC DATABOOK—1990<br>Circuit Characteristics • Ratings, Specifications and Waveforms • Design Considerations • 54F/74FXXX

## FAST ${ }^{\circledR}$ APPLICATIONS HANDBOOK—1990

Reprint of 1987 Fairchild FAST Applications Handbook
Contains application information on the FAST family: Introduction • Multiplexers • Decoders • Encoders
Operators • FIFOs • Counters • TTL Small Scale Integration • Line Driving and System Design
FAST Characteristics and Testing • Packaging Characteristics

## GENERAL PURPOSE LINEAR DEVICES DATABOOK—1989

Continuous Voltage Regulators • Switching Voltage Regulators • Operational Amplifiers • Buffers • Voltage Comparators Instrumentation Amplifiers • Surface Mount

GRAPHICS HANDBOOK—1989
Advanced Graphics Chipset • DP8500 Development Tools • Application Notes
INTERFACE DATABOOK—1990
Transmission Line Drivers/Receivers • Bus Transceivers • Peripheral Power Drivers • Display Drivers
Memory Support • Microprocessor Support • Level Translators and Buffers • Frequency Synthesis • Hi-Rel Interface

## LINEAR APPLICATIONS HANDBOOK—1986

The purpose of this handbook is to provide a fully indexed and cross-referenced collection of linear integrated circuit applications using both monolithic and hybrid circuits from National Semiconductor.
Individual application notes are normally written to explain the operation and use of one particular device or to detail various methods of accomplishing a given function. The organization of this handbook takes advantage of this innate coherence by keeping each application note intact, arranging them in numerical order, and providing a detailed Subject Index.

## LS/S/TTL DATABOOK—1989 <br> Contains former Fairchild Products <br> Introduction to Bipolar Logic •Low Power Schottky • Schottky • TTL • TTL—Low Power

## MASS STORAGE HANDBOOK—1989

Rigid Disk Pulse Detectors • Rigid Disk Data Separators/Synchronizers and ENDECs
Rigid Disk Data Controller • SCSI Bus Interface Circuits • Floppy Disk Controllers• Disk Drive Interface Circuits
Rigid Disk Preamplifiers and Servo Control Circuits • Rigid Disk Microcontroller Circuits • Disk Interface Design Guide
MEMORY DATABOOK—1990
PROMs, EPROMs, EEPROMs • TTL I/O SRAMs • ECL I/O SRAMs

## MICROCONTROLLER DATABOOK—1989

COP400 Family • COP800 Family • COPS Applications • HPC Family • HPC Applications MICROWIRE and MICROWIRE/PLUS Peripherals • Microcontroller Development Tools

## MICROPROCESSOR DATABOOK—1989

Series 32000 Overview • Central Processing Units • Slave Processors • Peripherals
Development Systems and Software Tools • Application Notes • NSC800 Family

## PROGRAMMABLE LOGIC DATABOOK \& DESIGN MANUAL-1990 <br> Product Line Overview • Datasheets • Designing with PLDs • PLD Design Methodology • PLD Design Development Tools Fabrication of Programmable Logic • Application Examples

## RELIABILITY HANDBOOK-1986

Reliability and the Die • Internal Construction • Finished Package • MIL-STD-883 • MIL-M-38510
The Specification Development Process • Reliability and the Hybrid Device • VLSI/VHSIC Devices
Radiation Environment • Electrostatic Discharge • Discrete Device • Standardization Quality Assurance and Reliability Engineering • Reliability and Documentation • Commercial Grade Device European Reliability Programs • Reliability and the Cost of Semiconductor Ownership
Reliability Testing at National Semiconductor • The Total Military/Aerospace Standardization Program 883B/RETSTM Products • MILS/RETSTM Products • 883/RETSTM Hybrids • MIL-M-38510 Class B Products Radiation Hardened Technology • Wafer Fabrication • Semiconductor Assembly and Packaging Semiconductor Packages • Glossary of Terms • Key Government Agencies • AN/ Numbers and Acronyms Bibliography • MIL-M-38510 and DESC Drawing Cross Listing

## SPECIAL PURPOSE LINEAR DEVICES DATABOOK-1989

Audio Circuits • Radio Circuits • Video Circuits • Motion Control Circuits • Special Function Circuits Surface Mount

## TELECOMMUNICATIONS—1990

Line Card Components • Integrated Services Digital Network Components • Analog Telephone Components Application Notes

    Note: ICC limit for 54 ACT @ $25^{\circ} \mathrm{C}$ is identical to 74 ACT @ $25^{\circ} \mathrm{C}$.

[^80]:    *All outputs loaded; thresholds on input associated with output under test
    $\dagger$ Maximum test duration 2.0 ms, one output loaded at a time.

[^81]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms, one output loaded at a time.

[^82]:    *All outputs loaded; thresholds on input associated with output under test.
    †Maximum test duration 2.0 ms , one output loaded at a time.
    Note: ICC for 54 ACT @ $25^{\circ} \mathrm{C}$ is identical to 74 ACT @ $25^{\circ} \mathrm{C}$.

[^83]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.
    Note: ICc limit for 54 ACT @ $25^{\circ} \mathrm{C}$ is identical to 74 ACT @ $25^{\circ} \mathrm{C}$.

[^84]:    *Maximum of 9 outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^85]:    *Voltage Range 5.0 is $5.0 \mathrm{~V} \pm 0.5 \mathrm{~V}$.
    Voltage Range 3.3 is $3.3 \mathrm{~V} \pm 0.3 \mathrm{~V}$.

[^86]:    *Voltage Range 5.0 is $5.0 \mathrm{~V} \pm 0.5 \mathrm{~V}$.

[^87]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^88]:    H $=$ HIGH Voltage Level
    L = LOW Voltage Level
    $\mathrm{X}=$ Immaterial
    $Z=$ High Impedance

[^89]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^90]:    H = HIGH Voitage Level
    L = LOW Voltage Level
    $\mathrm{X}=$ Immaterial
    Z $=$ High Impedance

[^91]:    ＊All outputs loaded；thresholds on input associated with output under test．
    $\dagger$ Maximum test duration 2.0 ms，one output loaded at a time．

[^92]:    *All outputs loaded; thresholds on input associated with output under test.

[^93]:    H＝HIGH Voltage Level
    L＝LOW Voltage Level
    $X=$ Immaterial
    $Z=$ High Impedance

[^94]:    ＊All outputs loaded thresholds on input associated with output under test．
    $\dagger$ Maximum test duration 2.0 ms ，one output loaded at a time．

[^95]:    H = HIGH Voltage Level
    L = LOW Voltage Level

[^96]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^97]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^98]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^99]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^100]:    H = HIGH Voltage Level
    L = LOW Voltage Level
    $\mathrm{X}=$ Immaterial
    $Z=$ High Impedance
    $\mathcal{\sim}=$ LOW-to-HIGH Transition

[^101]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^102]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^103]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^104]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^105]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms, one output loaded at a time.

[^106]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^107]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^108]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms , one output loaded at a time.

[^109]:    *All outputs loaded; thresholds on input associated with output under test.
    $\dagger$ Maximum test duration 2.0 ms, one output loaded at a time.
